Intel® Fortran Compiler User and Reference Guides

Document Number: 304970-006US

Contents

Legal Information.....77
Getting Help and Support.....79

Chapter 1: Introduction
Introducing the Intel(R) Fortran Compiler.....81
Notational Conventions.....81
Related Information.....87

Part I: Building Applications

Chapter 2: Overview: Building Applications
.....93

Chapter 3: Introduction: Basic Concepts
Choosing Your Development Environment.....95
Invoking the Intel® Fortran Compiler.....95
Default Tools.....97
Specifying Alternative Tools and Locations.....99
Compilation Phases.....99
Compiling and Linking for Optimization.....100
Compiling and Linking Multithread Programs.....101
What the Compiler Does by Default.....102
Generating Listing and Map Files.....103
Saving Compiler Information in your Executable.....104

Chapter 4: Building Applications from the Command Line
Using the Compiler and Linker from the Command Line.....107
Syntax for the ifort Command.....108
Examples of the ifort Command.....109
Creating, Running, and Debugging an Executable Program.....110
Redirecting Command-Line Output to Files.....113
Using Makefiles to Compile Your Application.....114
Specifying Memory Models to use with Systems Based on Intel® 64 Architecture.....115
Allocating Common Blocks.....116
Running Fortran Applications from the Command Line.....118

Chapter 5: Input and Output Files
Understanding Input File Extensions.....121
Producing Output Files.....122
Temporary Files Created by the Compiler or Linker.....124

Chapter 6: Setting Environment Variables
Using the ifortvars File to Specify Location of Components.....127
Setting Compile-Time Environment Variables.....129
Setting Run-Time Environment Variables.....132

Chapter 7: Using Compiler Options
Compiler Options Overview.....137
Using the Option Mapping Tool.....138
Compiler Directives Related to Options.....140

Chapter 8: Preprocessing
Using the fpp Preprocessor.....143
Using fpp Directives.....146
Using Predefined Preprocessor Symbols.....153

Chapter 9: Using Configuration Files and Response Files

Configuration Files and Response Files Overview.....157
Using Configuration Files.....157
Using Response Files.....158

Chapter 10: Debugging

Debugging Fortran Programs.....161
Preparing Your Program for Debugging.....161
Locating Unaligned Data.....164
Debugging a Program that Encounters a Signal or Exception...164
Debugging and Optimizations.....165
Debugging Multithreaded Programs.....168

Chapter 11: Data and I/O

Data Representation.....171
Data Representation Overview.....171
Integer Data Representations.....174
Logical Data Representations.....176
Character Representation.....178
Hollerith Representation.....179
Using Traceback Information.....181
Supported Native and Nonnative Numeric Formats.....181
Porting Nonnative Data.....187
Specifying the Data Format.....188
Fortran I/O.....197
Devices and Files Overview.....197
Logical Devices.....197
Types of I/O Statements.....201
Forms of I/O Statements.....203
Assigning Files to Logical Units.....205
File Organization.....208
Internal Files and Scratch Files.....209
File Access and File Structure.....210
File Records.....213

Record Types.....213
Record Length.....222
Record Access.....223
Record Transfer.....225
Specifying Default Pathnames and File Names.....227
Opening Files: OPEN Statement.....228
Obtaining File Information: INQUIRE Statement.....232
Closing Files: CLOSE Statement.....234
Record I/O Statement Specifiers.....235
File Sharing on Linux* OS and Mac OS* X Systems.....236
Specifying the Initial Record Position.....237
Advancing and Nonadvancing Record I/O.....238
User-Supplied OPEN Procedures: USEROPEN Specifier...238
Microsoft Fortran PowerStation Compatible Files.....246
Using Asynchronous I/O.....253

Chapter 12: Structuring Your Program

Structuring Your Program Overview.....257
Creating Fortran Executables.....257
Using Module (.mod) Files.....258
Using Include Files.....260
Advantages of Internal Procedures.....261
Storing Object Code in Static Libraries.....261
Storing Routines in Shareable Libraries.....261

Chapter 13: Programming with Mixed Languages

Programming with Mixed Languages Overview.....263
Calling Subprograms from the Main Program.....263
Summary of Mixed-Language Issues.....264
Adjusting Calling Conventions in Mixed-Language Programming.....266
Adjusting Calling Conventions in Mixed-Language Programming Overview.....266

ATTRIBUTES Properties and Calling Conventions.....268
Adjusting Naming Conventions in Mixed-Language Programming.....274
Adjusting Naming Conventions in Mixed-Language Programming Overview.....274
C/C++ Naming Conventions.....274
Procedure Names for Fortran, C, C++, and MASM.....275
Reconciling the Case of Names.....276
Fortran Module Names and ATTRIBUTES.....278
Prototyping a Procedure in Fortran.....279
Exchanging and Accessing Data in Mixed-Language Programming.....280
Exchanging and Accessing Data in Mixed-Language Programming.....280
Passing Arguments in Mixed-Language Programming.....281
Using Modules in Mixed-Language Programming.....283
Using Common External Data in Mixed-Language Programming.....285
Handling Data Types in Mixed-Language Programming.....289
Handling Data Types in Mixed-Language Programming Overview.....289
Handling Numeric, Complex, and Logical Data Types.....290
Handling Fortran Array Pointers and Allocatable Arrays.....293
Handling Integer Pointers.....294
Handling Arrays and Fortran Array Descriptors.....295
Handling Character Strings.....301
Handling User-Defined Types.....305
Intel(R) Fortran/Visual Basic* Mixed-Language Programs.....306
Interoperability with C.....306
Compiling and Linking Intel® Fortran/C Programs.....311
Calling C Procedures from an Intel® Fortran Program.....312

Chapter 14: Using Libraries

Supplied Libraries.....315
Creating Static Libraries.....319
Creating Shared Libraries.....321
Calling Library Routines.....323
Portability Considerations.....325
Portability Library Overview.....325
Using the IFPORT Portability Module.....325
Portability Routines.....326
Math Libraries.....329

Chapter 15: Error Handling

Handling Compile Time Errors.....331
Understanding Errors During the Build Process.....331
Compiler Message Catalog Support.....335
Using Source Code Verification.....336
Handling Run-Time Errors.....351
Understanding Run-Time Errors.....351
Run-Time Default Error Processing.....353
Run-Time Message Display and Format.....353
Values Returned at Program Termination.....356
Methods of Handling Errors.....357
Using the END, EOR, and ERR Branch Specifiers.....357
Using the IOSTAT Specifier and Fortran Exit Codes.....358
Locating Run-Time Errors.....359
List of Run-Time Error Messages.....361
Signal Handling (Linux* OS and Mac OS* X only).....410
Overriding the Default Run-Time Library Exception Handler.....411
Using Traceback Information.....412

Chapter 16: Portability Considerations

Portability Considerations Overview.....429
Understanding Fortran Language Standards.....429
Understanding Fortran Language Standards Overview...429
Using Standard Features and Extensions.....430
Using Compiler Optimizations.....431
Minimizing Operating System-Specific Information.....432
Storing and Representing Data.....432
Formatting Data for Transportability.....433

Chapter 17: Troubleshooting
Troubleshooting Your Application.....435

Chapter 18: Reference Information
Key Compiler Files Summary.....437
Compiler Limits.....438

Part II: Compiler Options

Chapter 19: Overview: Compiler Options
New Options.....444
Deprecated and Removed Compiler Options.....457

Chapter 20: Alphabetical Compiler Options
Compiler Option Descriptions and General Rules.....465
0 - 9

Chapter 21: Quick Reference Guides and Cross References

Windows* OS Quick Reference Guide and Cross Reference...1127
Linux* OS and Mac OS* X Quick Reference Guide and Cross Reference....1178

Chapter 22: Related Options

Linking Tools and Options....1229
Fortran Preprocessor Options....1232

Part III: Optimizing Applications

Chapter 23: Intel(R) Fortran Optimizing Applications

Overview: Optimizing Applications....1239
Optimizing with the Intel® Compiler....1239
Optimizing for Performance....1241
Overview of Parallelism Method....1242
Quick Reference Lists....1244
Other Resources....1245

Chapter 24: Evaluating Performance

Performance Analysis....1247
Using a Performance Enhancement Methodology....1247
Intel® Performance Analysis Tools and Libraries....1250
Performance Enhancement Strategies....1251

Using Compiler Reports.....1258
Compiler Reports Overview.....1258
Compiler Reports Quick Reference.....1258
Generating Reports.....1260
Interprocedural Optimizations (IPO) Report.....1263
Profile-guided Optimization (PGO) Report.....1269
High-level Optimization (HLO) Report.....1273
High Performance Optimizer (HPO) Report.....1286
Parallelism Report.....1287
Software Pipelining (SWP) Report (Linux* and Windows*).....1288
Vectorization Report.....1294
OpenMP* Report.....1299

Chapter 25: Using Compiler Optimizations

Automatic Optimizations Overview.....1301
Enabling Automatic Optimizations.....1302
Targeting IA-32 and Intel(R) 64 Architecture Processors Automatically.....1306
Targeting Multiple IA-32 and Intel(R) 64 Architecture Processors for Run-time Performance.....1310
Targeting IA-64 Architecture Processors Automatically.....1313
Restricting Optimizations.....1314

Chapter 26: Using Parallelism: OpenMP* Support

OpenMP* Support Overview.....1317
OpenMP* Options Quick Reference.....1318
OpenMP* Source Compatibility and Interoperability with Other Compilers.....1321
Using OpenMP*.....1323
Parallel Processing Model.....1326
Verifying OpenMP* Using Parallel Lint.....1331
OpenMP* Clauses".....1342

Data Scope Attribute Clauses Overview.....1342
Specifying Schedule Type and Chunk Size.....1342
COPYIN Clause.....1344
DEFAULT Clause.....1345
PRIVATE, FIRSTPRIVATE, and LASTPRIVATE Clauses....1346
REDUCTION Clause.....1348
SHARED Clause.....1351
OpenMP* Directives.....1352
Programming with OpenMP*.....1352
Combined Parallel and Worksharing Constructs.....1359
Parallel Region Directives.....1360
Synchronization Constructs.....1364
THREADPRIVATEthreadprivate Directive.....1370
Worksharing Construct Directives.....1371
Tasking Directives.....1374
OpenMP* Advanced Issues.....1375
OpenMP* Examples.....1379
Libraries, Directives, Clauses, and Environmental Variables...1383
OpenMP* Environment Variables.....1383
OpenMP* Directives and Clauses Summary.....1392
OpenMP* Library Support.....1398

Chapter 27: Using Parallelism: Automatic Parallelization

Auto-parallelization Overview.....1447
Auto-Parallelization Options Quick Reference.....1450
Auto-parallelization: Enabling, Options, Directives, and Environment Variables.....1451
Programming with Auto-parallelization.....1453
Programming for Multithread Platform Consistency.....1454

Chapter 28: Using Parallelism: Automatic Vectorization

Automatic Vectorization Overview.....1459
Automatic Vectorization Options Quick Reference.....1459

Programming Guidelines for Vectorization.....1461
Vectorization and Loops.....1462
Loop Constructs.....1466
Absence of Loop-carried Memory Dependency with IVDEP Directive.....1474
Vectorization Examples.....1475

Chapter 29: Using Parallelism: Multi-Threaded Applications

Creating Multithread Applications Overview.....1479
Basic Concepts of Multithreading.....1479
Developing Multithread Applications.....1480
Writing a Multithread Program Overview.....1480
Modules for Multithread Programs.....1481
Starting and Stopping Threads.....1481
Thread Routine Format.....1484
Sharing Resources.....1488
Thread Local Storage.....1491
Synchronizing Threads.....1491
Handling Errors in Multithread Programs.....1492
Table of Multithread Routines.....1492
Working with Multiple Processes.....1495

Chapter 30: Using Interprocedural Optimization (IPO)

Interprocedural Optimization (IPO) Overview.....1497
Interprocedural Optimization (IPO) Quick Reference.....1500
Using IPO.....1501
IPO-Related Performance Issues.....1504
IPO for Large Programs.....1504
Understanding Code Layout and Multi-Object IPO.....1506
Creating a Library from IPO Objects.....1508
Requesting Compiler Reports with the xi* Tools.....1510
Inline Expansion of Functions.....1511

Inline Function Expansion.....1511
Compiler Directed Inline Expansion of User Functions...1512
Developer Directed Inline Expansion of User Functions.....1514

Chapter 31: Using Profile-Guided Optimization (PGO)

Profile-Guided Optimizations Overview.....1519
Profile-Guided Optimization (PGO) Quick Reference.....1520
Profile an Application.....1530
PGO Tools.....1532
PGO Tools Overview.....1532
code coverage Tool.....1532
test prioritization Tool.....1552
profmerge and proforder Tools.....1561
Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations.....1566
Comparison of Function Order Lists and IPO Code Layout.....1573
PGO API Support.....1573
API Support Overview.....1573
PGO Environment Variables.....1574
Dumping Profile Information.....1576
Interval Profile Dumping.....1578
Resetting the Dynamic Profile Counters.....1579
Dumping and Resetting Profile Information.....1579

Chapter 32: Using High-Level Optimization (HLO)

High-Level Optimizations (HLO) Overview.....1581
Loop Unrolling.....1583
Loop Independence.....1584
Prefetching with Options.....1589

Chapter 33: Optimization Support Features

Optimization Support Features Overview.....1591
Loop Support.....1591
Loop Unrolling Support.....1595
Vectorization Support.....1596
Prefetching Support.....1602
Software Pipelining Support (IA-64 Architecture).....1605
About Register Allocation.....1606

Chapter 34: Programming Guidelines

Coding Guidelines for Intel® Architectures.....1611
Setting Data Type and Alignment.....1613
Using Arrays Efficiently.....1623
Improving I/O Performance.....1630
Improving Run-time Efficiency.....1636
Using Fortran Intrinsics.....1638
Understanding Run-time Performance.....1638
Understanding Data Alignment.....1642
Timing Your Application.....1643
Applying Optimization Strategies.....1647
Optimizing the Compilation Process.....1658
Optimizing the Compilation Process Overview.....1658
Efficient Compilation.....1658
Stacks: Automatic Allocation and Checking.....1660
Little-endian-to-Big-endian Conversion (IA-32 Architecture).....1664
Symbol Visibility Attribute Options (Linux* and Mac OS* X).....1669
Data Alignment Options.....1671

Part IV: Floating-point Operations

Chapter 35: Overview: Floating-point Operations

Chapter 36: Floating-point Options Quick Reference

Chapter 37: Understanding Floating-point Operations

Programming Tradeoffs in Floating-point Applications.....1681
Floating-point Optimizations.....1682
Using the -fp-model (/fp) Option.....1684
Denormal Numbers.....1688
Floating-point Environment.....1688
Setting the FTZ and DAZ Flags.....1689
Checking the Floating-point Stack State.....1691

Chapter 38: Tuning Performance

Overview: Tuning Performance.....1693
Avoiding Exact Floating-point Comparison.....1693
Handling Floating-point Array Operations in a Loop Body.....1694
Reducing the Impact of Denormal Exceptions.....1694
Avoiding Mixed Data Type Arithmetic Expressions.....1696
Using Efficient Data Types.....1698

Chapter 39: Handling Floating-point Exceptions

Overview: Controlling Floating-point Exceptions.....1699
Handling Floating-point Exceptions.....1700
File fordef.for and Its Usage.....1703
Setting and Retrieving Floating-point Status and Control Words (IA-32).....1706
Overview: Setting and Retrieving Floating-point Status and Control Word.....1706
Understanding Floating-point Status Word.....1709
Floating-point Control Word Overview.....1710
Using Exception, Precision, and Rounding Parameters...1711
Handling Floating-point Exceptions with the -fpe or /fpe Compiler Option.....1714

Using the -fpe or /fpe Compiler Options.....1714
Understanding the Impact of Application Types.....1717

Chapter 40: Understanding IEEE Floating-point Operations

Overview: Understanding IEEE Floating-point Standard.....1721
Floating-point Formats.....1721
Limitations of Numeric Conversion.....1721
Special Values.....1722
Representing Floating-point Numbers.....1724
Floating-point Representation.....1724
Retrieving Parameters of Numeric Representations.....1725
ULPs, Relative Error, and Machine Epsilon.....1727
Native IEEE Floating-point Representation.....1728
Handling Exceptions and Errors.....1732
Loss of Precision Errors.....1732
Rounding Errors.....1733

Part V: Language Reference

Chapter 41: Overview: Language Reference

New Language Features.....1739

Chapter 42: Conformance, Compatibility, and Fortran 2003 Features

Language Standards Conformance.....1741
Language Compatibility.....1741
Fortran 2003 Features.....1741

Chapter 43: Program Structure, Characters, and Source Forms

Program Structure.....1745
Statements.....1746

Names.....1748
Keywords.....1750
Character Sets.....1750
Source Forms.....1752
Free Source Form.....1754
Fixed and Tab Source Forms.....1757
Source Code Useable for All Source Forms.....1761

Chapter 44: Data Types, Constants, and Variables

Intrinsic Data Types.....1763
Integer Data Types.....1765
Real Data Types.....1769
Complex Data Types.....1774
General Rules for Complex Constants.....1775
COMPLEX(4) Constants.....1775
COMPLEX(8) or DOUBLE COMPLEX Constants.....1776
COMPLEX(16) Constants.....1777
Logical Data Types.....1778
Logical Constants.....1779
Character Data Type.....1779
Character Constants.....1780
C Strings in Character Constants.....1781
Character Substrings.....1783
Derived Data Types.....1784
Derived-Type Definition.....1785
Default Initialization.....1785
Structure Components.....1786
Structure Constructors.....1790
Binary, Octal, Hexadecimal, and Hollerith Constants.....1792
Binary Constants.....1792
Octal Constants.....1793
Hexadecimal Constants.....1793

Hollerith Constants.....1794
Determining the Data Type of Nondecimal Constants...1795
Variables.....1798
Data Types of Scalar Variables.....1799
Arrays.....1800

Chapter 45: Expressions and Assignment Statements

Expressions.....1817
Numeric Expressions.....1818
Character Expressions.....1823
Relational Expressions.....1823
Logical Expressions.....1825
Defined Operations.....1827
Summary of Operator Precedence.....1827
Initialization and Specification Expressions.....1828
Assignment Statements.....1833
Intrinsic Assignments.....1833
Defined Assignments.....1839
Pointer Assignments.....1840
WHERE Statement and Construct Overview.....1843
FORALL Statement and Construct Overview.....1843

Chapter 46: Specification Statements

Type Declaration Statements.....1846
Declaration Statements for Noncharacter Types.....1847
Declaration Statements for Character Types.....1849
Declaration Statements for Derived Types.....1852
Declaration Statements for Arrays.....1853
ALLOCATABLE Attribute and Statement Overview.....1862
ASYNCHRONOUS Attribute and Statement Overview.....1862
AUTOMATIC and STATIC Attributes and Statements Overview.....1862
BIND Attribute and Statement Overview.....1862

COMMON Statement Overview.....1862
DATA Statement Overview.....1863
DIMENSION Attribute and Statement Overview.....1863
EQUIVALENCE Statement Overview.....1863
Making Arrays Equivalent.....1863
Making Substrings Equivalent.....1865
EQUIVALENCE and COMMON Interaction.....1870
EXTERNAL Attribute and Statement Overview.....1872
IMPLICIT Statement Overview.....1872
INTENT Attribute and Statement Overview.....1872
INTRINSIC Attribute and Statement Overview.....1872
NAMELIST Statement Overview.....1873
OPTIONAL Attribute and Statement Overview.....1873
PARAMETER Attribute and Statement Overview.....1873
POINTER Attribute and Statement Overview.....1873
PROTECTED Attribute and Statement Overview.....1873
PUBLIC and PRIVATE Attributes and Statements Overview....1873
SAVE Attribute and Statement Overview.....1873
TARGET Attribute and Statement Overview.....1874
VALUE Attribute and Statement Overview.....1874
VOLATILE Attribute and Statement Overview.....1874

Chapter 47: Dynamic Allocation

ALLOCATE Statement Overview.....1875
Allocation of Allocatable Arrays.....1876
Allocation of Pointer Targets.....1877
DEALLOCATE Statement Overview.....1878
Deallocation of Allocatable Arrays.....1878
Deallocation of Pointer Targets.....1880
NULLIFY Statement Overview.....1881

Chapter 48: Execution Control

Branch Statements.....1883

Unconditional GO TO Statement Overview.....1884
Computed GO TO Statement Overview.....1884
The ASSIGN and Assigned GO TO Statements Overview.....1884
Arithmetic IF Statement Overview.....1885
CALL Statement Overview.....1885
CASE Constructs Overview.....1885
CONTINUE Statement Overview.....1885
DO Constructs Overview.....1885
Forms for DO Constructs.....1886
Execution of DO Constructs.....1886
DO WHILE Statement Overview.....1894
CYCLE Statement Overview.....1894
EXIT Statement Overview.....1894
END Statement Overview.....1894
IF Construct and Statement Overview.....1894
IF Construct Overview.....1894
IF Statement Overview.....1894
PAUSE Statement Overview.....1894
RETURN Statement Overview.....1895
STOP Statement Overview.....1895

Chapter 49: Program Units and Procedures

Main Program.....1898
Modules and Module Procedures.....1898
Module References.....1899
USE Statement.....1899
Intrinsic Modules.....1900
ISO_C_BINDING.....1901
ISO_FORTRAN_ENV.....1904
IEEE Intrinsic Modules and Procedures.....1906
Block Data Program Units.....1914

Functions, Subroutines, and Statement Functions.....1914
General Rules for Function and Subroutine Subprograms.....1915
Functions.....1916
Subroutines.....1918
Statement Functions.....1918
External Procedures.....1918
Internal Procedures.....1918
Argument Association.....1920
Optional Arguments.....1923
Array Arguments.....1924
Pointer Arguments.....1925
Assumed-Length Character Arguments.....1926
Character Constant and Hollerith Arguments.....1927
Alternate Return Arguments.....1928
Dummy Procedure Arguments.....1929
References to Generic Procedures.....1930
References to Non-Fortran Procedures.....1935
Procedure Interfaces.....1935
Determining When Procedures Require Explicit Interfaces.....1937
Defining Explicit Interfaces.....1938
Defining Generic Names for Procedures.....1938
Defining Generic Operators.....1940
Defining Generic Assignment.....1942
CONTAINS Statement Overview.....1944
ENTRY Statement Overview.....1944
ENTRY Statements in Function Subprograms.....1944
ENTRY Statements in Subroutine Subprograms.....1945
IMPORT Statement Overview.....1946

Chapter 50: Intrinsic Procedures

Argument Keywords in Intrinsic Procedures.....1949
Overview of Bit Functions.....1951
Categories and Lists of Intrinsic Procedures.....1953
Categories of Intrinsic Functions.....1953
Intrinsic Subroutines.....1975

Chapter 51: Data Transfer I/O Statements

Records and Files.....1979
Components of Data Transfer Statements.....1980
I/O Control List.....1981
I/O Lists.....1990
READ Statements.....1997
Forms for Sequential READ Statements.....1998
Forms for Direct-Access READ Statements.....2012
Forms for Stream READ Statements.....2014
Forms and Rules for Internal READ Statements.....2014
ACCEPT Statement Overview.....2017
WRITE Statements.....2017
Forms for Sequential WRITE Statements.....2017
Forms for Direct-Access WRITE Statements.....2026
Forms for Stream WRITE Statements.....2027
Forms and Rules for Internal WRITE Statements.....2027
PRINT and TYPE Statements Overview.....2028
REWRITE Statement Overview.....2029

Chapter 52: I/O Formatting

Format Specifications.....2031
Data Edit Descriptors.....2039
Forms for Data Edit Descriptors.....2040
General Rules for Numeric Editing.....2042
Integer Editing.....2044
Real and Complex Editing.....2049
Logical Editing (L).....2061

Character Editing (A).....2062
Default Widths for Data Edit Descriptors.....2065
Terminating Short Fields of Input Data.....2066
Control Edit Descriptors.....2068
Forms for Control Edit Descriptors.....2068
Positional Editing.....2070
Sign Editing.....2071
Blank Editing.....2073
Scale-Factor Editing (P).....2074
Slash Editing (/).....2077
Colon Editing (:).....2079
Dollar-Sign ($) and Backslash (\ ) Editing.....2079
Character Count Editing (Q).....2080
Character String Edit Descriptors.....2083
Character Constant Editing.....2083
H Editing.....2084
Nested and Group Repeat Specifications.....2086
Variable Format Expressions.....2086
Printing of Formatted Records.....2089
Interaction Between Format Specifications and I/O Lists.....2090

Chapter 53: File Operation I/O Statements

BACKSPACE Statement Overview.....2103
CLOSE Statement Overview.....2103
DELETE Statement Overview.....2103
ENDFILE Statement Overview.....2103
FLUSH Statement Overview.....2103
INQUIRE Statement Overview.....2103
ACCESS Specifier.....2104
ACTION Specifier.....2104
ASYNCHRONOUS Specifier.....2105
BINARY Specifier (W*32, W*64).....2105

BLANK Specifier.....2106
BLOCKSIZE Specifier.....2106
BUFFERED Specifier.....2106
CARRIAGECONTROL Specifier.....2107
CONVERT Specifier.....2107
DELIM Specifier.....2108
DIRECT Specifier.....2109
EXIST Specifier.....2109
FORM Specifier.....2110
FORMATTED Specifier.....2110
ID Specifier.....2111
IOFOCUS Specifier (W*32, W*64).....2111
MODE Specifier.....2112
NAME Specifier.....2112
NAMED Specifier.....2112
NEXTREC Specifier.....2113
NUMBER Specifier.....2113
OPENED Specifier.....2113
ORGANIZATION Specifier.....2114
PAD Specifier.....2114
PENDING Specifier.....2114
POS Specifier.....2115
POSITION Specifier.....2116
READ Specifier.....2116
READWRITE Specifier.....2117
RECL Specifier.....2117
RECORDTYPE Specifier.....2117
SEQUENTIAL Specifier.....2118
SHARE Specifier.....2119
UNFORMATTED Specifier.....2120
WRITE Specifier.....2120
OPEN Statement Overview.....2120

ACCESS Specifier.....2125
ACTION Specifier.....2125
ASSOCIATEVARIABLE Specifier.....2126
ASYNCHRONOUS Specifier.....2126
BLANK Specifier.....2127
BLOCKSIZE Specifier.....2127
BUFFERCOUNT Specifier.....2128
BUFFERED Specifier.....2128
CARRIAGECONTROL Specifier.....2129
CONVERT Specifier.....2130
DEFAULTFILE Specifier.....2133
DELIM Specifier.....2133
DISPOSE Specifier.....2134
FILE Specifier.....2134
FORM Specifier.....2136
IOFOCUS Specifier (W*32, W*64).....2137
MAXREC Specifier.....2138
MODE Specifier.....2138
NAME Specifier.....2138
NOSHARED Specifier.....2138
ORGANIZATION Specifier.....2138
PAD Specifier.....2139
POSITION Specifier.....2139
READONLY Specifier.....2140
RECL Specifier.....2141
RECORDSIZE Specifier.....2143
RECORDTYPE Specifier.....2143
SHARE Specifier.....2144
SHARED Specifier.....2146
STATUS Specifier.....2146
TITLE Specifier (W*32, W*64).....2147
TYPE Specifier.....2148

USEROPEN Specifier.....2148
REWIND Statement Overview.....2155
WAIT Statement Overview.....2155

Chapter 54: Compilation Control Lines and Statements

Chapter 55: Directive Enhanced Compilation
Syntax Rules for Compiler Directives.....2159
General Compiler Directives.....2160
Rules for General Directives that Affect DO Loops.....2162
Rules for Loop Directives that Affect Array Assignment Statements.....2163
OpenMP* Fortran Compiler Directives.....2164
Data Scope Attribute Clauses.....2166
Conditional Compilation Rules.....2167
Nesting and Binding Rules.....2168

Chapter 56: Scope and Association
Scope.....2171
Unambiguous Generic Procedure References.....2175
Resolving Procedure References.....2175
References to Generic Names.....2176
References to Specific Names.....2179
References to Nonestablished Names.....2180
Association.....2181
Name Association.....2183
Pointer Association.....2185
Storage Association.....2186

Chapter 57: Deleted and Obsolescent Language Features
Deleted Language Features in Fortran 95.....2191
Obsolescent Language Features in Fortran 95.....2191
Obsolescent Language Features in Fortran 90.....2193

Chapter 58: Additional Language Features

FORTRAN 66 Interpretation of the EXTERNAL Statement.....2195
Alternative Syntax for the PARAMETER Statement.....2198
Alternative Syntax for Binary, Octal, and Hexadecimal Constants.....2199
Alternative Syntax for a Record Specifier.....2200
Alternative Syntax for the DELETE Statement.....2200
Alternative Form for Namelist External Records.....2200
Record Structures.....2201
Structure Declarations.....2203
References to Record Fields.....2204
Aggregate Assignment.....2209

Chapter 59: Additional Character Sets

Character and Key Code Charts for Windows* OS.....2211
ASCII Character Codes for Windows* Systems.....2211
ANSI Character Codes for Windows* Systems.....2214
Key Codes for Windows* Systems.....2216
ASCII Character Set for Linux* OS and Mac OS* X.....2219

Chapter 60: Data Representation Models

Model for Integer Data.....2224
Model for Real Data.....2225
Model for Bit Data.....2227

Chapter 61: Run-Time Library Routines

Module Routines.....2229
OpenMP* Fortran Routines.....2230

Chapter 62: Summary of Language Extensions

Source Forms.....2233
Names.....2234

Character Sets.....2234
Intrinsic Data Types.....2234
Constants.....2235
Expressions and Assignment.....2235
Specification Statements.....2235
Execution Control.....2235
Program Units and Procedures.....2236
Compilation Control Lines and Statements.....2236
Built-In Functions.....2236
I/O Statements.....2236
I/O Formatting.....2237
File Operation Statements.....2237
Compiler Directives.....2239
Intrinsic Procedures.....2240
Additional Language Features.....2244
Run-Time Library Routines.....2245

Chapter 63: A to Z Reference

Language Summary Tables.....2248
Statements for Program Unit Calls and Definitions.....2249
Statements Affecting Variables.....2250
Statements for Input and Output.....2252
Compiler Directives.....2253
Program Control Statements and Procedures.....2258
Inquiry Intrinsic Functions.....2260
Random Number Intrinsic Procedures.....2262
Date and Time Intrinsic Subroutines.....2263
Keyboard and Speaker Library Routines.....2264
Statements and Intrinsic Procedures for Memory Allocation and Deallocation.....2264
Intrinsic Functions for Arrays.....2265
Intrinsic Functions for Numeric and Type Conversion...2267

Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures....2269
Intrinsic Functions for Floating-Point Inquiry and Control....2273
Character Intrinsic Functions....2275
Intrinsic Procedures for Bit Operation and Representation....2277
QuickWin Library Routines (W*32, W*64)....2279
Graphics Library Routines (W*32, W*64)....2282
Portability Library Routines....2288
National Language Support Library Routines (W*32, W*64)....2301
POSIX* Library Procedures....2304
Dialog Library Routines (W*32, W*64)....2312
COM and Automation Library Routines (W*32, W*64))....2314
Miscellaneous Run-Time Library Routines....2317
Intrinsic Functions Not Allowed as Actual Arguments...2319
A to B....2319
ABORT....2319

Legal Information

INFORMATION IN THIS DOCUMENT IS PROVIDED IN CONNECTION WITH INTEL(R) PRODUCTS. NO LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE, TO ANY INTELLECTUAL PROPERTY RIGHTS IS GRANTED BY THIS DOCUMENT. EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER, AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

UNLESS OTHERWISE AGREED IN WRITING BY INTEL, THE INTEL PRODUCTS ARE NOT DESIGNED NOR INTENDED FOR ANY APPLICATION IN WHICH THE FAILURE OF THE INTEL PRODUCT COULD CREATE A SITUATION WHERE PERSONAL INJURY OR DEATH MAY OCCUR.

Intel may make changes to specifications and product descriptions at any time, without notice. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. The information here is subject to change without notice. Do not finalize a design with this information.

The products described in this document may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

Copies of documents which have an order number and are referenced in this document, or other Intel literature, may be obtained by calling 1-800-548-4725, or by visiting Intel's Web Site.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See http://www.intel.com/products/processor_number for details.

Getting Help and Support

The Intel® Fortran Compiler lets you build and optimize Fortran applications for the Linux* OS (operating system).

For more information about the compiler features and other components, see your *Release Notes*.

This documentation assumes that you are familiar with the Fortran programming language and with your processor's architecture. You should also be familiar with the host computer's operating system.

Product Website and Support

For general information on support for Intel software products, visit the Intel web site http://www.intel.com/software/products/

At this site, you will find comprehensive product information, including:

- Links to each product, where you will find technical information such as white papers and articles
- Links to user forums
- Links to news and events

To find technical support information, to register your product, or to contact Intel, please visit: http://www.intel.com/software/products/support/

For additional information, see the Technical Support section of your Release Notes.

System Requirements

For detailed information on system requirements, see the Release Notes.

Introduction

1

Introducing the Intel® Fortran Compiler

The Intel® Fortran Compiler can generate code for IA-32, Intel® 64, or IA-64 architecture applications on any Intel®-based Linux* system. IA-32 architecture applications (32-bit) can run on all Intel®-based Linux systems. Intel® 64 architecture applications and IA-64 architecture applications can run only on Intel® 64 architecture-based or IA-64 architecture-based Linux systems. You can use the compiler on the command line.

You can find further information in the following documents:

- Building Applications
- Compiler Options
- Optimizing Applications
- Floating-point Operations
- Language Reference

Notational Conventions

Information in this documentation applies to all supported operating systems and architectures unless otherwise specified.

This documentation uses the following conventions:

- Notational Conventions
- Platform Labels

Notational Conventions

THIS TYPE	Indicates statements, data types, directives, and other language keywords. Examples of statement keywords are WRITE, INTEGER, DO, and OPEN.

this type	Indicates command-line or option arguments, new terms, or emphasized text. Most new terms are defined in the Glossary.
`This type`	Indicates a code example.
`This type`	Indicates what you type as input.
This type	Indicates menu names, menu items, button names, dialog window names, and other user-interface items.
File>Open	Menu names and menu items joined by a greater than (>) sign indicate a sequence of actions. For example, "Click **File>Open**" indicates that in the **File** menu, click **Open** to perform this action.
{value | value}	Indicates a choice of items or values. You can usually only choose one of the values in the braces.
[*item*]	Indicates items that are optional. Brackets are also used in code examples to show arrays.
item [, *item*]...	Indicates that the item preceding the ellipsis (three dots) can be repeated. In some code examples, a horizontal ellipsis means that not all of the statements are shown.
Windows* OS Windows operating system	These terms refer to all supported Microsoft* Windows* operating systems.
Linux* OS Linux operating system	These terms refer to all supported Linux* operating systems.
Mac OS* X Mac OS X operating system	These terms refer to Intel©-based systems running the Mac OS* X operating system.

Microsoft Windows XP*	An asterisk at the end of a word or name indicates it is a third-party product trademark.
compiler option	This term refers to Windows* OS options, Linux* OS options, or MAC OS* X options that can be used on the compiler command line.

Conventions Used in *Compiler Options*

`/option` or `-option`	A slash before an option name indicates the option is available on Windows OS. A dash before an option name indicates the option is available on Linux OS* and Mac OS* X systems. For example: Windows option: `/fast` Linux and Mac OS X option: `-fast` Note: If an option is available on Windows* OS, Linux* OS, and Mac OS* X systems, no slash or dash appears in the general description of the option. The slash and dash will only appear where the option syntax is described.
`/option:argument` or `-option argument`	Indicates that an option requires a argument (parameter). For example, you must specify an argument for the following options: Windows OS option: `/Qdiag-error-limit:`*n* Linux OS and Mac OS X option: `-diag-error-limit` *n*
`/option:`*keyword* or `-option` *keyword*	Indicates that an option requires one of the *keyword* values.
`/option`[:*keyword*] or -option [*keyword*]	Indicates that the option can be used alone or with an optional keyword.

`option[n]` or `option[:n]` or `option[=n]`	Indicates that the option can be used alone or with an optional value; for example, in `/Qfnalign[:n]` and `-falign-functions[=n]`, the *n* can be omitted or a valid value can be specified for *n*.
`option[-]`	Indicates that a trailing hyphen disables the option; for example, `/Qglobal_hoist-` disables the Windows OS option `/Qglobal_hoist`.
`[no]option` or `[no-]option`	Indicates that "no" or "no-" preceding an option disables the option. For example: In the Windows OS option `/[no]traceback`, `/traceback` enables the option, while `/notraceback` disables it. In the Linux OS and Mac OS X option `-[no-]global_hoist`, `-global_hoist` enables the option, while `-no-global_hoist` disables it. In some options, the "no" appears later in the option name; for example, `-fno-alias` disables the `-falias` option.

Conventions Used in *Language Reference*

This color	Indicates extensions to the Fortran 95 Standard. These extensions may or may not be implemented by other compilers that conform to the language standard.
Intel Fortran	This term refers to the name of the common compiler language supported by the Intel® Fortran Compiler.
Fortran	This term refers to language information that is common to ANSI FORTRAN 77, ANSI/ISO Fortran 95 and 90, and Intel Fortran.

Fortran 95/90	This term refers to language information that is common to ANSI FORTRAN 77, ANSI/ISO Fortran 95, ANSI/ISO Fortran 90, and Intel Fortran.
Fortran 95	This term refers to language features specific to ANSI/ISO Fortran 95.
integer	This term refers to the INTEGER(KIND=1), INTEGER(KIND=2), INTEGER (INTEGER(KIND=4)), and INTEGER(KIND=8) data types as a group.
real	This term refers to the REAL (REAL(KIND=4)), DOUBLE PRECISION (REAL(KIND=8)), and REAL(KIND=16) data types as a group.
REAL	This term refers to the default data type of objects declared to be REAL. REAL is equivalent to REAL(KIND=4), unless a compiler option specifies otherwise.
complex	This term refers to the COMPLEX (COMPLEX(KIND=4)), DOUBLE COMPLEX (COMPLEX(KIND=8)), and COMPLEX(KIND=16) data types as a group.
logical	This term refers to the LOGICAL(KIND=1), LOGICAL(KIND=2), LOGICAL (LOGICAL(KIND=4)), and LOGICAL(KIND=8) data types as a group.
Compatibility	This term introduces a list of the projects or libraries that are compatible with the library routine.
< Tab>	This symbol indicates a nonprinting tab character.

^	This symbol indicates a nonprinting blank character.

Platform Labels

A platform is a combination of operating system and central processing unit (CPU) that provides a distinct environment in which to use a product (in this case, a computer language). An example of a platform is Microsoft* Windows* XP on processors using IA-32 architecture.

In this documentation, information applies to all supported platforms unless it is otherwise labeled for a specific platform (or platforms).

These labels may be used to identify specific platforms:

L*X	Applies to Linux* OS on processors using IA-32 architecture, Intel® 64 architecture, and IA-64 architecture.
L*X32	Applies to Linux* OS on processors using IA-32 architecture and Intel® 64 architecture.
L*X64	Applies to Linux OS on processors using IA-64 architecture.
M*X	Applies to Apple* Mac OS* X on processors using IA-32 architecture and Intel® 64 architecture.
M*X32	Applies to Apple* Mac OS* X on processors using IA-32 architecture.
M*X64	Applies to Apple* Mac OS* X on processors using Intel® 64 architecture.
W*32	Applies to Microsoft Windows* 2000, Windows XP, and Windows Server 2003 on processors using IA-32 architecture and Intel® 64 architecture. For a complete list of supported Windows* operating systems, see your Release Notes.

W*64	Applies to Microsoft Windows* XP operating systems on IA-64 architecture.
i32	Applies to 32-bit operating systems on IA-32 architecture.
i64em	Applies to 32-bit operating systems on Intel® 64 architecture.
i64	Applies to 64-bit operating systems on IA-64 architecture.

Overview: Building Applications 2

Welcome to the Intel® Fortran Compiler.

This Building Applications document explains how to use the Intel® Compiler to build applications on Linux*, Windows*, and Mac OS* X operating systems. Intel® Fortran provides you with a variety of alternatives for building applications. Depending on your needs, you can build your source code into several types of programs and libraries using the command line. Additionally, on Windows systems, you can use the Microsoft Visual Studio* integrated development environment (IDE) and on Mac OS X operating systems, you can use the Xcode* IDE to build your application.

The discussions in this document often contain content that applies generally to all supported operating systems; however, where the expected behavior is significantly different on a specific OS, the appropriate behavior is listed separately.

In general, the compiler features and options supported on Linux OS using IA-32 architecture or Intel® 64 architecture are also supported on Intel®-based systems running Mac OS X. For more detailed information about support for specific operating systems, refer to the appropriate option in the Compiler Options reference or the Release Notes.

Introduction: Basic Concepts 3

Choosing Your Development Environment

Depending on your operating system, you can build programs from the command line and/or from an IDE such as Microsoft Visual Studio* (Windows* OS) or Xcode* (Mac OS* X).

An IDE offers a number of ways to simplify the task of compiling and linking programs. It provides a default text editor. You can also use your favorite text editor outside the integrated development environment.

Because software development is an iterative process, it is important to be able to move quickly and efficiently to various locations in your source code. If you use an IDE to build your programs, you can display both the description of the error message and the relevant source code directly from the displayed error messages.

When you build programs from the command line, you may have more control of the build tools. If you choose to, you can customize how your program is built by your selection of compiler and linker options. Compiler options are described in the Compiler Options Reference.

See Also

- Introduction: Basic Concepts
- Invoking the Intel® Fortran Compiler
- Using the Compiler and Linker from the Command Line

Invoking the Intel® Fortran Compiler

The command to invoke the compiler is `ifort`.

Requirements Before Using the Command Line

On Linux* and Mac OS* X operating systems, you need to set some environment variables to specify locations for the various components prior to using the command line. The Intel Fortran Compiler installation includes a shell script that you can run to set environment variables. For more information, see Using the ifortvars File to Specify Location of Components.

On Windows* operating systems, you typically do not need to set any environment variables prior to using the command line. Each of the Intel® Fortran Compiler variations has its own Intel Compiler command-line window, available from the Intel Fortran program folder. This window has the appropriate environment variables already set for the command-line environment.

Using the ifort Command from the Command Line

Use the `ifort` command either on a command line or in a makefile to invoke the Intel Fortran compiler. The syntax is:

`ifort [options]input_file(s)`

For a complete listing of compiler options, see the Compiler Options reference.

You can specify more than one input_file, using a space as a delimiter. See Understanding Input File Extensions.

For more information on ifort syntax, see Syntax for the ifort Command.

NOTE. For Windows and Mac OS* X systems, you can also use the compiler from within the integrated development environment.

You can use the command-line window to invoke the Intel Fortran Compiler in a number of ways, detailed below.

Using makefiles from the Command Line

Use makefiles to specify a number of files with various paths and to save this information for multiple compilations. For more information on using makefiles, see Using Makefiles to Compile Your Application.

Using the devenv command from the Command Line (Windows only)

Use `devenv` to set various options for the integrated development environment (IDE) as well as build, clean, and debug projects from the command line. For more information on the `devenv` command, see the `devenv` description in the Microsoft Visual Studio* documentation.

Using a .bat file from the Command Line

Use a .bat file to consistently execute the compiler with a desired set of options. This spares you retyping the command each time you need to recompile.

Default Tools

The default tools are summarized in the table below.

Tool	Default	Provided with Intel® Fortran Compiler?
Assembler for IA-32 architecture-based applications and Intel® 64 architecture-based applications	MASM* (Windows OS)	No
	operating system assembler, as (Linux OS and Mac OS X)	No
Assembler for IA-64 architecture-based applications	`ias`	Yes
Linker	Microsoft* linker (Windows OS)	No
	System linker, ld(1) (Linux OS and Mac OS X)	No

You can specify alternative tools and locations for preprocessing, compilation, assembly, and linking.

Assembler

By default, the compiler generates an object file directly without calling the assembler. However, if you need to use specific assembly input files and then link them with the rest of your project, you can use an assembler for these files.

IA-32 architecture-based applications

Use any 32-bit assembler. For Windows, you can use the Microsoft Macro Assembler* (MASM), version 6.15 or higher, to link assembly language files with the object files generated by the compiler.

Intel® 64 architecture-based applications

For Windows systems, use the MASM provided on the Microsoft SDK. For Linux OS and Mac OS X systems, use the operating system assembler, `as`.

IA-64 architecture-based applications

Use the assembler, `ias`. The following example compiles a Fortran file to an assembly language file, which you can modify as desired. The assembler is then used to create an object file.

Use the `-S` (Linux) or `/asmfile:file.asm` (Windows) option to generate an assembly code file.

- The following command line on Linux OS and Mac OS X generates the assembly code file, `file.s`:

  ```
  ifort -S -c file.f
  ```

- The following command line on Windows OS generates the assembly code for `file.asm`:

  ```
  ifort /asmfile:file /c file.f
  ```

To assemble the file just produced, call the IA-64 architecture assembler.

- The following is the Linux OS command line:

  ```
  ias -Nso -p32 -o file.o file.s
  ```

- The following is the Windows OS command line:

  ```
  ias /Nso /p32 /o file.obj file.asm
  ```

  where the following assembler options are used:

  - Nso suppresses the sign-on message
  - p32 enables defining 32-bit elements as relocatable data elements; kept for backward compatibility
  - The file specified by the `o` option indicates the output object file name

The above `ias` command generates an object file, which you can link with the object file of the project.

Linker

On Linux OS and Mac OS X, the compiler calls the system linker, `ld(1)`, to produce an executable file from the object file.

On Windows OS, the compiler calls the Microsoft linker, `link`, to produce an executable file from the object files. The linker searches the path specified in the environment variable `LIB` to find any library files.

Specifying Alternative Tools and Locations

The Intel® Fortran Compiler lets you specify alternatives to default tools and locations for preprocessing, compilation, assembly, and linking. In addition, you can invoke options specific to the alternate tools on the command line. This functionality is provided by the `-Qlocation` or `/Qlocation` and `-Qoption` or `/Qoption` options.

For more information see the following topics:

- Qlocation compiler option
- Qoption compiler option

Compilation Phases

When invoked, the compiler driver determines which compilation phases to perform based on the extension of the source filename and on the compilation options specified in the command line.

The table that follows shows the compilation phases and the software that controls each phase.

Phase	Software	Architecture (IA-32, Intel® 64, or IA-64)
Preprocess (optional)	`fpp`	All
Compile	`fortcom`	All

Phase	Software	Architecture (IA-32, Intel® 64, or IA-64)
Assemble	IAS or MASM (Windows OS)	IAS for IA-64 architecture based applications;Microsoft Macro Assembler* (MASM) can be used for IA-32 architecture based applications. See Default Tools for more information.
	as or ias (Linux OS)	as for IA-32 architecture-based applications and Intel® 64 architecture-based applications; ias for IA-64 architecture-based applications
Link	LINK (Windows OS)	All
	ld(1) (Linux OS and Mac OS X)	All

By default, the compiler driver performs the compile and link phases to produce the executable file.

The compiler driver passes object files and any unrecognized filename to the linker. The linker then determines whether the file is an object file or a library. For Linux OS and Mac OS X, the linker can also determine whether the file is a shared library (.so).

The compiler driver handles all types of input files correctly. Therefore, it can be used to invoke any phase of compilation.

The compiler processes Fortran language source and generates object files. You decide the input and output by setting options when you run the compiler.

When invoked, the compiler determines which compilation phases to perform based on the extension of the source filename and on the compilation options specified in the command line.

Compiling and Linking for Optimization

By default, all Fortran source files are separately compiled into individual object files.

If you want to allow full interprocedural optimizations to occur, you must use the -ipo (Linux OS and Mac OS X) or /Qipo (Windows OS) option.

By default, compilation is done with `-O2` (Linux OS and Mac OS X) or `/O2` (Windows). If you want to see if your code will benefit from some added optimizations, use `O3`. These aggressive optimizations may or may not improve your code speed.

For complete information about optimization, see Compiler Optimizations Overview in Optimizing Applications.

Compiling and Linking Multithread Programs

To build a multithread application that uses the Fortran run-time libraries, specify the `-threads` (Linux* OS and Mac OS* X) or `/threads` (Windows* OS) compiler option from the command line. For Windows systems, you can use also use the Microsoft integrated development environment (IDE), as described later in this topic.

You must also link with the correct library files.

The following applies to Linux OS and Mac OS X:

To create statically linked multithread programs, link with the static library named libifcoremt.a. To use shared libraries, link your application with libifcoremd.so (Linux OS) or libifcoremd.dylib (Mac OS X).

The following applies to Windows OS:

To create statically linked multithread programs, link with the re-entrant support library LIBIFCOREMT.LIB. To use shared libraries, use the shared LIBIFCOREMD.DLL library, which also re-entrant, and is referenced by linking your application with the LIBIFCOREMD.LIB import library.

Programs built with LIBIFCOREMT.LIB do not share Fortran run-time library code or data with any dynamic-link libraries they call. You must link with LIBIFCOREMD.LIB if you plan to call a DLL.

Additional Notes for Windows OS:

- The `/threads` compiler option is automatically set when you specify a multithread application in the visual development environment.
- Specify the compiler options `/libs=dll` and /threads if you are using both multithreaded code and DLLs. You can use the `/libs=dll` and `/threads` options only with Fortran Console projects, not QuickWin applications.

To compile and link your multithread program from the command line:

1. Make sure your IA32ROOT or IA64ROOT (Linux OS and Mac OS X) or LIB (Windows) environment variable points to the directory containing your library files.
2. Compile and link the program with the `-threads` (Linux OS and Mac OS X) or `/threads` (Windows) compiler option.

For example:

`ifort -threads mythread.f90` (Linux OS and Mac OS X)

`ifort /threads mythread.f90` (Windows OS)

To compile and link your multithread program using the IDE (Windows OS):

1. Create a new project by clicking File > New > Project.
2. Click **Intel Fortran Projects** in the left pane to display the Intel Fortran project types. Choose the project type.
3. Add the file containing the source code to the project.
4. From the **Project** menu, select **Properties**.

   The **Property Pages** dialog box appears.
5. Choose the **Fortran** folder, **Libraries** category, and set the Runtime Library to Multithreaded or Multithread DLL (or their debug equivalents).
6. Create the executable file by choosing Build Solution from the **Build** menu.

What the Compiler Does by Default

By default, the compiler driver generates executable file(s) of the input file(s) and performs the following actions:

- Displays certain diagnostic messages, warnings, and errors.
- Performs default settings and optimizations, unless these options are overridden by specific options settings.
- Searches for source files in the current directory or in the directory path explicitly specified before a file name (for example, looks in "src" when the directory path is `src\test.f90`).
- Searches for include and module files in:
  - The directory path explicitly specified before a file name (for example, looks in "src" when the including source is specified as `src\test.f90`)
  - The current directory
  - The directory specified by using the `-module path` (Linux* OS and Mac OS* X) or `/module:path` (Windows* OS) option (for all module files)
  - The directory specified by using the `-I`*`dir`* ((Linux OS and Mac OS X) or `/I`*`dir`* (Windows OS) option (for module files referenced in USE statements and include files referenced in INCLUDE statements.)

  - For Windows OS, the include path specified by the INCLUDE environment variable (for all include or module files)
  - Any directory explicitly specified in any INCLUDE within an included file

- Passes options designated for linking as well as user-defined libraries to the linker. The linker searches for any library files in directories specified by the LIB variable, if they are not found in the current directory.

For unspecified options, the compiler uses default settings or takes no action.

You may want to use the `-assume keyword` (Linux OS and Mac OS X) or `/assume:keyword` (Windows OS) option to instruct the compiler to make certain assumptions. For example, `-assume buffered_io` tells the compiler to accumulate records in a buffer. For more information and the complete list of supported keywords, see the assume option reference page.

NOTE. On operating systems that support characters in Unicode* (multi-byte) format, the compiler will process file names containing Unicode* characters.

Generating Listing and Map Files

Compiler-generatedassembler output listings and linker-generated map files can help you understand the effects of compiler optimizations and see how your application is laid out in memory. They may also help you interpret the information provided in a stack trace at the time of an error.

How to Generate Assembler Output

When compiling from the command line, specify the `-S` (Linux* OS and Mac OS* X) or `/asmattr` option with one of its keyword (Windows* OS):

```
ifort -S file.f90 (Linux OS and Mac OS X)
ifort file.f90 /asmattr:all (Windows OS)
```

On Linux OS and Mac OS X, the resulting assembly file name has a .s suffix. On Windows OS, the resulting assembly file name has an .asm suffix.

Additionally, on Windows OS, you can use the Visual Studio integrated development environment:

1. Select Project>Properties.
2. Click the Fortran tab.

3. In the Output Files category, change the Assembler Output settings according to your needs. You can choose from a number of options such as No Listing, Assembly-only Listing, and Assembly, Machine Code and Source.

How to Generate a Link Map (.map) File

When compiling from the command line, specify the `-Xlinker` and `-M` options (Linux OS and Mac OS X) or the `/map` (Windows) option:

```
ifort file.f90 -Xlinker -M  (Linux OS and Mac OS X)
ifort file.f90 /map (Windows)
```

Additionally, on Windows systems, you can use the Visual Studio integrated development environment:

1. Select Project>Properties.
2. Click the Linker tab.
3. In the Debug category, select Generate Map File.

Saving Compiler Information in your Executable

If you want to save information about the compiler in your executable, use the `-sox` (Linux* OS) or `/Qsox` (Windows* OS) option. When you use this option, the following information is saved:

- compiler version number
- compiler options that were used to produce the executable

On Linux OS:

To view the information stored in string format in the object file, use the following command:

```
strings -a a.out|grep comment:
```

On Windows OS:

To view the linker directives stored in string format in the object file, use the following command:

```
link /dump /directives filename.obj
```

The `-?comment` linker directive displays the compiler version information.

To search your executable for compiler information, use the following command:

```
findstr "Compiler" filename.exe
```

This searches for any strings that have the substring "Compiler" in them.

Building Applications from the Command Line

4

Using the Compiler and Linker from the Command Line

The `ifort` command is used to compile and link your programs from the command line.

You can either compile and link your projects in one step with the `ifort` command, or compile them with `ifort` and then link them as a separate step.

In most cases, you will use a single `ifort` command to invoke the compiler and linker.

You can use the `ifort` command in either of two windows:

- Your own terminal window, in which you have set the appropriate environment variables by executing the file called `ifortvars.sh` or `ifortvars.csh` (Linux* OS and Mac OS* X) or `ifortvars.bat` (Windows* OS). This file sets the environment variables such as PATH. By default, the `ifortvars` file is installed in the `\bin` directory for your compiler. For more information, see Using the ifortvars File to Specify Location of Components.
- On Windows operating systems, the supplied Fortran command-line window in the Intel® Fortran program folder, in which the appropriate environment variables in `ifortvars.bat` are preset.

The `ifort` command invokes a *`driver program`* that is the actual user interface to the compiler and linker. It accepts a list of command options and file names and directs processing for each file.

The driver program does the following:

- Calls the Intel® Fortran Compiler to process Fortran files.
- Passes the linker options to the linker.
- Passes object files created by the compiler to the linker.
- Passes libraries to the linker.
- Calls the linker or librarian to create the executable or library file.

You can also use `ld` (Linux OS and Mac OS X) or `link` (Windows OS) to build libraries of object modules. These commands provide syntax instructions at the command line if you request it with the `/?` or `/help` option.

The`ifort` command automatically references the appropriate Intel Fortran Run-Time Libraries when it invokes the linker. Therefore, to link one or more object files created by the Intel Fortran compiler, you should use the `ifort` command instead of the `link` command.

Because the driver calls other software components, error messages may be returned by these other components. For instance, the linker may return a message if it cannot resolve a global reference. The `-watch` (Linux OS and Mac OS X) or `/watch` (Windows OS) command-line option can help clarify which component is generating the error.

NOTE. Windows systems support characters in Unicode* (multibyte) format; the compiler will process file names containing Unicode* characters.

Syntax for the ifort Command

Use the syntax below to invoke the Intel® Fortran Compiler from the command line:

```
ifort  [options]input_file(s)
```

An option is specified by one or more letters preceded by a hyphen (-) for Linux and Mac OS* X operating systems and a slash (/) for the Windows* operating system. (You can use a hyphen (-) instead of a slash for Windows OS, but this is not the preferred method.)

The following rules apply:

- Some options take arguments in the form of filenames, strings, letters, or numbers. Except where otherwise noted, you can enter a space between the option and its argument(s) or you can combine them. For a complete listing of compiler options, see the Compiler Options reference.
- You can specify more than one input_file , using a space as a delimiter. When a file is not in your path or working directory, specify the directory path before the file name. The filename extension specifies the type of file.

NOTE. Options on the command line apply to all files. For example, in the following command line, the `-c` and `-nowarn` options apply to both files `x.f` and `y.f`:

```
ifort -c x.f -nowarn y.f
```

- You cannot combine options with a single slash or hyphen, but must specify the slash or hyphen for each option specified. For example, this is correct: /1 /c

  But this is not: /1c
- Some compiler options are case-sensitive. For example, c and C are two different options.
- Options can take arguments in the form of filenames, strings, letters, and numbers. If a string includes spaces, it must be enclosed in quotation marks.

- All compiler options must precede the `-Xlinker` (Linux OS and Mac OS X) or `/link` (Windows OS) options. Options that appear following -Xlinker or /link are passed directly to the linker.
- Unless you specify certain options, the command line will both compile and link the files you specify. To compile without linking, specify the `-c` (Linux OS and Mac OS X) or `/c` (Windows OS) option.
- You can abbreviate some option names, entering as many characters as are needed to uniquely identify the option.
- Compiler options remain in effect for the whole compilation unless overridden by a compiler directive.
- On Windows OS, certain options accept one or more keyword arguments following the option name. To specify multiple keywords, you typically specify the option multiple times. However, some options allow you to use comma-separated keywords. For example:

```
ifort /warn:usage,declarations test.f90
```

You can use an equals sign (=) instead of the colon:

```
ifort /warn=usage,declarations test.f90
```

Examples of the ifort Command

This topic provides some examples of valid `ifort` commands. It also shows various ways to compile and link source files.

Compiling and Linking a Single Source File

The following command compiles `x.for`, links, and creates an executable file. This command generates a temporary object file, which is deleted after linking:

```
ifort x.for
```

To specify a particular name for the executable file, specify the -o (Linux* OS and Mac OS* X) or `/exe` (Windows* OS) option:

```
ifort x.for -o myprog.out (Linux OS and Mac OS X)
ifort x.for /exe:myprog.exe (Windows OS)
```

Compiling, but not Linking, a Source File

The following command compiles `x.for` and generates the object file `x.o` (Linux OS and Mac OS X) or `x.obj` (Windows OS). The `c` option prevents linking (it does not link the object file into an executable file):

```
ifort -c x.for (Linux OS and Mac OS X)
ifort x.for /c (Windows OS)
```

The following command links `x.o` or `x.obj` into an executable file. This command automatically links with the default Intel Fortran libraries:

```
ifort x.o (Linux OS and Mac OS X)
ifort x.obj (Windows OS)
```

Compiling and Linking Multiple Fortran Source Files

The following command compiles `a.for`, `b.for`, and `c.for`. It creates three temporary object files, then links the object files into an executable file named `a.out` (on Linux OS and Mac OS X) or `a.exe` (Windows OS):

```
ifort a.for b.for c.for
```

When you use modules and compile multiple files, compile the source files that define modules *before* the files that reference the modules (in `USE` statements).

When you use a single `ifort` command, the order in which files are placed on the command line is significant. For example, if the free-form source file `moddef.f90` defines the modules referenced by the file `projmain.f90`, use the following command:

```
ifort moddef.f90 projmain.f90
```

Creating, Running, and Debugging an Executable Program

The example below shows a sample Fortran main program using free source form that uses a module and an external subprogram.

The function CALC_AVERAGE is contained in a separate file and depends on the module ARRAY_CALCULATOR for its interface block.

The USE statement accesses the module ARRAY_CALCULATOR. This module contains the function declaration for CALC_AVERAGE.

The 5-element array is passed to the function CALC_AVERAGE, which returns the value to the variable AVERAGE for printing.

The example is:

```
! File: main.f90
! This program calculates the average of five numbers
PROGRAM MAIN
USE ARRAY_CALCULATOR
REAL, DIMENSION(5) :: A = 0
REAL :: AVERAGE
PRINT *, 'Type five numbers: '
READ  (*,'(F10.3)') A

AVERAGE = CALC_AVERAGE(A)
PRINT *, 'Average of the five numbers is: ', AVERAGE
END PROGRAM MAIN
```

The example below shows the module referenced by the main program. This example program shows more Fortran 95/90 features, including an interface block and an assumed-shape array:

```
! File: array_calc.f90.
! Module containing various calculations on arrays.
MODULE ARRAY_CALCULATOR
INTERFACE
FUNCTION CALC_AVERAGE(D)
REAL :: CALC_AVERAGE
REAL, INTENT(IN) :: D(:)
END FUNCTION CALC_AVERAGE
END INTERFACE
! Other subprogram interfaces...
END MODULE ARRAY_CALCULATOR
```

The example below shows the function declaration CALC_AVERAGE referenced by the main program:

```
! File: calc_aver.f90.
! External function returning average of array.
FUNCTION CALC_AVERAGE(D)
REAL :: CALC_AVERAGE
REAL, INTENT(IN) :: D(:)
CALC_AVERAGE = SUM(D) / UBOUND(D, DIM = 1)
END FUNCTION CALC_AVERAGE
```

Commands to Create a Sample Program

During the early stages of program development, the sample program files shown above might be compiled separately and then linked together, using the following commands:

Linux OS and Mac OS* X example:

1. `ifort -c array_calc.f90`
2. `ifort -c calc_aver.f90`

3. `ifort -c main.f90`
4. `ifort -o calc main.o array_calc.o calc_aver.o`

Windows* example:

1. `ifort /c array_calc.f90`
2. `ifort /c calc_aver.f90`
3. `ifort /c main.f90`
4. `ifort /exe:calc main.obj array_calc.obj calc_aver.obj`

In this sequence of commands:

Line 1: The `-c` (Linux OS and Mac OS X) or `/c` (Windows OS) option prevents linking and retains the object files. This command creates the module file `array_calculator.mod` and the object file `array_calc.o` (Linux OS and Mac OS X) or array_calc.obj (Windows OS). Note that the name in the MODULE statement determines the name of module file `array_calculator.mod`. Module files are written into the current working directory.

Line 2: This command creates the object file `calc_aver.o` (Linux OS and Mac OS X) or `calc_aver.obj` (Windows OS).

Line 3: This command creates the object file `main.o` (Linux OS and Mac OS X) or `main.out` (Windows OS)and uses the module file `array_calculator.mod`.

Line 4: This command links all object files into the executable program named `calc`. To link files, use the `ifort` command instead of the `ld` command.

Running the Sample Program

If your path definition includes the directory containing `calc`, you can run the program by simply entering its name:

```
calc
```

When running the sample program, the PRINT and READ statements in the main program result in the following dialogue between user and program:

```
Type five numbers:
55.5
4.5
3.9
9.0
5.6
Average of the five numbers is:   15.70000
```

Debugging the Sample Program

To debug a program with the debugger, compile the source files with the `-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS) option to request additional symbol table information for source line debugging in the object and executable program files.

The following `ifort` command lines for Linux OS and Mac OS X systems use the `-o` option to name the executable program file `calc_debug`. The Mac OS X command line also uses the `-save-temps` option, which specifies that the object files should be saved; otherwise, they will be deleted by default.

```
ifort -g -o calc_debug array_calc.f90 calc_aver.f90 main.f90 (Linux)
ifort -g -save-temps -o calc_debug array_calc.f90 calc_aver.f90 main.f90 (Mac OS X)
```

The Windows OS equivalent of this command is the following:

```
ifort /debug:full /exe:calc_debug array_calc.f90 calc_aver.f90 main.f90
```

See also Debugging Fortran Programs and related sections.

Redirecting Command-Line Output to Files

When using the command line, you can redirect standard output and standard error to a file. This avoids displaying a lot of text, which will slow down execution; scrolling text in a terminal window on a workstation can cause an I/O bottleneck (increased elapsed time) and use more CPU time.

Linux* OS and Mac OS* X:

The following example applies to Linux* OS and Mac OS* X.

To run the program more efficiently, redirect output to a file and then display the program output:

```
myprog > results.lis
more results.lis
```

Windows* OS:

The following examples apply to Windows OS.

To place standard output into file `one.out` and standard error into file `two.out`, use the `ifort` command as follows:

```
ifort filenames /options 1>one.out 2>two.out
```

You can also use a short-cut form (omit the 1):

```
ifort filenames /options >one.out 2>two.out
```

To place standard output and standard error into a single file `both.out`, enter the `ifort` command as follows:

```
ifort filenames /options 1>both.out 2>&1
```

You can also use a short-cut form (omit the 1):

```
ifort filenames /options >both.out 2>&1
```

Using Makefiles to Compile Your Application

To specify a number of files with various paths and to save this information for multiple compilations, you can use a makefile.

Linux OS and Mac OS X:

To use a makefile to compile your input files, make sure that /usr/bin and /usr/local/bin are in your path.

If you use the C shell, you can edit your `.cshrc` file and add the following:

```
setenv PATH  /usr/bin:/usr/local/bin:yourpath
```

Then you can compile as:

```
make -f yourmakefile
```

where `-f` is the `make` command option to specify a particular makefile.

Windows OS:

To use a makefile to compile your input files, use the `nmake` command. For example, if your project is `your_project.mak`:

```
nmake /f your_project.mak FPP=ifort.exe LINK32=xilink.exe
```

The arguments of this `nmake` command are as follows:

`/f`	A particular makefile.
your_project.mak	A makefile you want to use to generate object and executable files.
FPP	The compiler-invoking command you want to use. The name of this macro might be different for your makefile. This command invokes the preprocessor.
LINK32	The linker you want to use.

The `nmake` command creates object files (`.obj`) and executable files (`.exe`) specified in `your_project.mak` file.

Specifying Memory Models to use with Systems Based on Intel® 64 Architecture

The following applies to Linux* operating systems only.

Applications designed to take advantage of Intel® 64 architecture can be built with one of three memory models:

- `small (-mcmodel=small)`

  This causes code and data to be restricted to the first 2GB of address space so that all accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.

- `medium (-mcmodel=medium)`

  This causes code to be restricted to the first 2GB; however, there is no restriction on data. Code can be addressed with IP-relative addressing, but access of data must use absolute addressing.

- `large (-mcmodel=large)`

  There are no restrictions on code or data; access to both code and data uses absolute addressing.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. This can affect code size and performance. (IP-relative addressing is somewhat faster.)

Additional Notes on Memory Models and on Large Data Objects

- When you specify the medium or large memory models, you must also specify the `-shared-intel` compiler option to ensure that the correct dynamic versions of the Intel run-time libraries are used.
- When you build shared objects (.so), Position-Independent Code (PIC) is specified (that is, `-fpic` is added by the compiler driver) so that a single .so can support all three memory models. However, code that is to be placed in a static library, or linked statically, must be built with the proper memory model specified. Note that there is a performance impact to specifying the medium or large memory models.
- The use of the memory model (medium, large) option and the `-shared-intel` option is required as a by-product of the code models stipulated in the 64-bit Application Binary Interface (ABI), which is written specifically for processors with the 64-bit memory extensions. Both the compiler and the GNU linker (ld) are responsible for generating the proper code and necessary relocations on this platform according to the chosen memory model.

- The 2GB restriction on Intel® 64 architecture involves not only arrays greater than 2GB, but also COMMON blocks and local data with a total size greater than 2GB. The Compiler Options reference contains additional discussion of the supported memory models and offers details about the 2GB restrictions for each model. See the `-mcmodel` options page.

- If, during linking, you fail to use the appropriate memory model and dynamic library options, an error message in this format occurs:

```
<some lib.a library>(some .o): In Function <function>:
  : relocation truncated to fit: R_X86_64_PC32 <some symbol>
```

Allocating Common Blocks

Use the `-dyncom` (Linux OS and Mac OS X) or `/Qdyncom` (Windows OS) option to dynamically allocate common blocks at run time.

This option designates a common block to be dynamic. The space for its data is allocated at run time rather than compile time. On entry to each routine containing a declaration of the dynamic common block, a check is performed to see whether space for the common block has been allocated. If the dynamic common block is not yet allocated, space is allocated at the check time.

The following command-line example specifies the dynamic common option with the names of the common blocks to be allocated dynamically at run time:

```
ifort -dyncom "blk1,blk2,blk3" test.f (Linux OS and Mac OS X)
ifort /Qdyncom"BLK1,BLK2,BLK3" test.f (Windows OS)
```

where `BLK1`, `BLK2`, and `BLK3`are the names of the common blocks to be made dynamic.

Guidelines for Using the dyncom/Qdyncom Option

The following are some limitations that you should be aware of when using the `-dyncom` (Linux OS and Mac OS X) or `/Qdyncom` (Windows OS) option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
- Only named common blocks can be designated as dynamic COMMON.
- An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

For more information, see the following topic:

- `-dyncom` compiler option

Why Use a Dynamic Common Block?

A main reason for using dynamic common blocks is to enable you to control the common block allocation by supplying your own allocation routine. To use your own allocation routine, you should link it ahead of the Fortran run-time library. This routine must be written in the C language to generate the correct routine name.

The routine prototype is:

```
void _FTN_ALLOC(void **mem, int *size, char *name);
```

where

- *mem* is the location of the base pointer of the common block which must be set by the routine to point to the block of memory allocated.
- *size* is the integer number of bytes of memory that the compiler has determined are necessary to allocate for the common block as it was declared in the program. You can ignore this value and use whatever value is necessary for your purpose.

NOTE. You must return the size in bytes of the space you allocate. The library routine that calls `_FTN_ALLOC()` ensures that all other occurrences of this common block fit in the space you allocated. Return the size in bytes of the space you allocate by modifying *size*.

- *name* is the name of the common block being dynamically allocated.

Allocating Memory to Dynamic Common Blocks

The run-time library routine, `f90_dyncom`, performs memory allocation. The compiler calls this routine at the beginning of each routine in a program that contains a dynamic common block. In turn, this library routine calls `_FTN_ALLOC()` to allocate memory. By default, the compiler passes the size in bytes of the common block as declared in each routine to `f90_dyncom`, and then on to `_FTN_ALLOC()`. If you use the nonstandard extension having the common block of the same name declared with different sizes in different routines, you might get a run-time error depending on the order in which the routines containing the common block declarations are invoked.

The Fortran run-time library contains a default version of `_FTN_ALLOC()`, which simply allocates the requested number of bytes and returns.

Running Fortran Applications from the Command Line

If you run a program from the command line, the operating system searches directories listed in the PATH environment variable to find the executable file you have requested.

You can also run your program by specifying the complete path of the executable file. On Windows* operating systems, any DLLs you are using must be in the same directory as the executable or in one specified in the path.

Multithreaded Programs

If your program is multithreaded, each thread starts on whichever processor is available at the time. On a computer with one processor, the threads all run in parallel, but not simultaneously; the single processor switches among them. On a computer with more than one processor, the threads can run simultaneously.

Using the fpscomp:filesfromcmd Option

If you specify the `-fpscomp filefromcmd` (Linux OS and Mac OS X) or `/fpscomp:filesfrom-cmd` (Windows OS) option, the command line that executes the program can also include additional filenames to satisfy `OPEN` statements in your program in which the filename field (FILE specifier) has been left blank. The first filename on the command line is used for the first such `OPEN` statement executed, the second filename for the second `OPEN` statement, and so on. (In the Visual Studio IDE, you can provide these filenames using Project>Properties. Choose the Debugging category and enter the filenames in the Command Arguments text box.)

Each filename on the command line (or in an IDE dialog box) must be separated from the names around it by one or more spaces or tab characters. You can enclose each name in quotation marks ("*filename*"), but this is not required unless the argument contains spaces or tabs. A null argument consists of an empty set of quotation marks with no filename enclosed ("").

The following example runs the program MYPROG.EXE from the command line:

```
MYPROG "" OUTPUT.DAT
```

Because the first filename argument is null, the first `OPEN` statement with a blank filename field produces the following message:

```
File name missing or blank - please enter file name
UNIT number  ?
```

The *number* is the unit number specified in the OPEN statement. The filename OUTPUT.DAT is used for the second such OPEN statement executed. If additional OPEN statements with blank filename fields are executed, you will be prompted for more filenames.

Instead of using the -fpscomp filesfromcmd or /fpscomp:filesfromcmd option, you can:

- Call the GETARG library routine to return the specified command-line argument. To execute the program in the Visual Studio IDE, provide the command-line arguments to be passed to the program using Project>Properties. Choose the Debugging category and enter the arguments in the Command Arguments text box .
- On Windows OS, call the GetOpenFileName Windows API routine to request the file name using a dialog box.

For more information, see the following topic:

- fpscomp compiler option

5 Input and Output Files

Understanding Input File Extensions

The Intel® Fortran compiler interprets the type of each input file by the file name extension.

The file extension determines whether a file gets passed to the compiler or to the linker. The following types of files are used with the ifort command:

- Files passed to the compiler: `.f90`, `.for`, `.f`, `.fpp`, `.i`, `.i90`, `.ftn`

  Typical Fortran source files have a file extension of .f90, .for, and .f. When editing your source files, you need to choose the source form, either free-source form or fixed-source form (or a variant of fixed form called tab form). You can either use a compiler option to specify the source form used by the source files (see the description for the free or fixed compiler option) or you can use specific file extensions when creating or renaming your files. For example:

  - The compiler assumes that files with an extension of .f90 or .i90 are free-form source files.
  - The compiler assumes that files with an extension of .f, .for, .ftn, or .i are fixed-form (or tab-form) files.

- Files passed to the linker: `.a`, `.lib`, `.obj`, `.o`, `.exe`, `.res`, `.rbj`, `.def`, `.dll`

The most common file extensions and their interpretations are:

Filename	Interpretation	Action
filename`.a` (Linux* OS and Mac OS* X) *filename*`.lib` (Windows* OS)	Object library	Passed to the linker.
filename`.f` *filename*`.for` *filename*`.ftn` *filename*`.i`	Fortran fixed-form source	Compiled by the Intel® Fortran compiler.

Filename	Interpretation	Action
filename.fpp and, on Linux, filenames with the following uppercase extensions: .FPP, .F, .FOR, .FTN	Fortran fixed-form source	Automatically preprocessed by the Intel Fortran preprocessor fpp; then compiled by the Intel Fortran compiler.
filename.f90 *filename*.i90	Fortran free-form source	Compiled by the Intel Fortran compiler.
filename.F90 (Linux OS and Mac OS X)	Fortran free-form source	Automatically preprocessed by the Intel Fortran preprocessor fpp; then compiled by the Intel Fortran compiler.
filename.s (Linux OS and Mac OS X) *filename*.asm (Windows)	Assembly file	Passed to the assembler.
filename.o (Linux OS and Mac OS X) *filename*.obj (Windows OS)	Compiled object file	Passed to the linker.

When you compile from the command line, you can use the compiler configuration file to specify default directories for input libraries. To specify additional directories for input files, temporary files, libraries, and for the files used by the assembler and the linker, use compiler options that specify output file and directory names.

Producing Output Files

The output produced by the ifort command includes:

- An object file, if you specify the -c (Linux OS and Mac OS X) or /c (Windows OS) option on the command line. An object file is created for each source file.
- An executable file, if you omit the -c or /c option.
- One or more module files (such as datadef.mod), if the source file contains one or more MODULE statements.

- A shareable library (such as `mylib.so` on Linux OS, `mylib.dylib` on Mac OS X, or`mylib.dll` on Windows OS), if you use the `-shared` (Linux),`-dynamiclib` (Mac OS X) or `/libs:dll` (Windows OS) option.
- Assembly files, if you use the `-S` (Linux OS and Mac OS X) or `/S` (Windows OS) option. This creates an assembly file for each source file.

You control the production of output files by specifying the appropriate compiler options on the command line or using the appropriate properties in the integrated development environment for Windows OS and Mac OS X.

For instance, if you do not specify the `-c` or `/c` option, the compiler generates a temporary object file for each source file. It then invokes the linker to link the object files into one executable program file and causes the temporary object files to be deleted.

If you specify the `-c` or `/c` option, object files are created and retained in the current working directory. You must link the object files later. You can do this by using a separate ifort command; alternatively, you can call the linker (`ld` for Linux OS and Mac OS X or `link` for Windows OS) directly to link in objects. On Linux OS and Mac OS X systems, you can also call `xild` or use the archiver (ar) and xiar to create a library. For Mac OS X, you would use `libtool` to generate a library.

If fatal errors are encountered during compilation, or if you specify certain options such as `-c` or `/c`, linking does not occur.

The output files include the following:

Output File	Extension	How Created on the Command Line
Object file	.o (Linux OS and Mac OS X) .obj (Windows OS)	Created automatically.
Executable file	.out (Linux OS and Mac OS X) .exe (Windows OS)	Do not specify `-c` or `/c`.
Shareable library file	.so (Linux OS) .dylib (Mac OS X) .dll (Windows OS)	Specify `-shared` (Linux OS),`-dynamiclib` (Mac OS X) or `/libs:dll` (Windows OS) and do not specify `-c` or `/c` .

Output File	Extension	How Created on the Command Line
Module file	.mod	Created if a source file being compiled defines a Fortran module (MODULE statement).
Assembly file	.s (Linux OS and Mac OS* X) .asm (Windows OS)	Created if you specify the `S` option. An assembly file for each source file is created.

To allow optimization across all objects in the program, use the `-ipo/Qipo` option.

To specify a file name for the executable program file (other than the default) use the `-o` *`output`* (Linux OS and Mac OS X) or `/exe:`*`output`* (Windows OS) option, where `output` specifies the file name.

NOTE. You cannot use the `c` and `o` options together with multiple source files.

Temporary Files Created by the Compiler or Linker

Temporary files created by the compiler or linker reside in the directory used by the operating system to store temporary files.

To store temporary files, the driver first checks for the TMP environment variable. If defined, the directory that TMP points to is used to store temporary files.

If the TMP environment variable is not defined, the driver then checks for the TMPDIR environment variable. If defined, the directory that TMPDIR points to is used to store temporary files.

If the TMPDIR environment variable is not defined, the driver then checks for the TEMP environment variable. If defined, the directory that TEMP points to is used to store temporary files.

For Windows* OS, if the TEMP environment variable is not defined, the current working directory is used to store temporary files. For Linux* OS and Mac OS* X, if the TEMP environment variable is not defined, the `/tmp` directory is used to store temporary files.

Temporary files are usually deleted. Use the `-save-temps` (Linux OS and Mac OS X) or `/Qsave-temps` (Windows OS) compiler option to save temporary files created by the compiler in the current working directory. This option only saves intermediate files that are normally created during compilation.

For performance reasons, use a local drive (rather than a network drive) to contain temporary files.

To view the file name and directory where each temporary file is created, use the `-watch all` (Linux OS and Mac OS X) or `/watch:all` (Windows OS) option.

To create object files in your current working directory, use the `-c` (Linux OS and Mac OS X) or `/c` (Windows OS) option.

Any object files that you specify on the command line are retained.

Setting Environment Variables 6

Using the ifortvars File to Specify Location of Components

Before you first invoke the compiler, you need to be sure certain environment variables are set. These environment variables define the location of the various compiler-related components.

The Intel Fortran Compiler installation includes a file that you can run to set environment variables.

- On Linux* OS and Mac OS* X, the file is a shell script called `ifortvars.sh` or `ifortvars.csh`.
- On Windows* OS, the file is a batch file called `ifortvars.bat`.

The following information is operating system-dependent.

Linux OS and Mac OS X:

Set the environment variables before using the compiler. You can use the `source` command to execute the shell script, `ifortvars.sh` or `ifortvars.csh`, from the command line to set them.

The script takes an architecture argument:

- ia32: Compiler and libraries for IA-32 architecture only
- intel64: Compiler and libraries for Intel® 64 architecture only
- ia64: Compiler and libraries for IA-64 architectures only (Linux OS)

For example, to execute this script file for the bash shell:

```
source /opt/intel/Compiler/version_number/package_id/bin/ifortvars.sh ia32
```

If you use the C shell, use the `.csh` version of this script file:

```
source /opt/intel/Compiler/version_number/package_id/bin/ifortvars.csh ia32
```

If you want `ifortvars.sh` to run automatically when you start Linux OS or Mac OS X, you can edit your `.bash_profile` file and add the line above to the end of your file. For example:

```
# set up environment for Intel compiler
source /opt/intel/fc/version_number/package_id/bin/ifortvars.sh ia32
```

If you compile a program without ensuring the proper environment variables are set, you will see an error similar to the following when you execute the compiled program:

```
./a.out: error while loading shared libraries:
libimf.so: cannot open shared object file: No such file or directory
```

Windows OS:

Under normal circumstances, you do not need to run the ifortvars.bat batch file. The Fortran command-line window sets these variables for you automatically.

To activate this command-line window, select **Fortran Build Environment for applications...** available from the **Start>All Programs>Intel(R) Software Development Tools>Intel(R) Visual Fortran Compiler Professional**

NOTE. You will need to run the batch file if you open a command-line window without using the provided Build Environment for applications... menu item in the Intel Fortran program folder or if you want to use the compiler from a script of your own.

The batch file inserts the directories used by Intel Fortran at the beginning of the existing paths. Because these directories appear first, they are searched before any directories in the path lists provided by Windows OS. This is especially important if the existing path includes directories with files having the same names as those needed by Intel Fortran.

If needed, you can run `ifortvars.bat`each time you begin a session on Windows* systems by specifying it as the initialization file with the PIF Editor.

The batch file takes two arguments:

```
<install-dir>\bin\ifortvars.bat <arg1> [<arg2>]
```

`<arg1>` is one of the following

- ia32: Compiler and libraries for IA-32 architecture only
- ia32_intel64: Compiler running on IA-32 architecture that generates code for Intel® 64 architecture; uses Intel® 64 architecture libraries
- ia32_ia64: Compiler running on IA-32 architecture that generates code for IA-64 architecture; uses IA-64 architecture libraries
- intel64: Compiler and libraries for Intel® 64 architecture only
- ia64: Compiler and libraries for IA-64 architectures only

`<arg2>`, if specified, is one of the following:

- vs2005: Microsoft Visual Studio 2005
- vs2008: Microsoft Visual Studio 2008

If <arg2> is not specified, the script uses the version of Visual Studio that was detected during the installation procedure.

Setting Compile-Time Environment Variables

The following table shows the compile-time environment variables that affect the Intel® Fortran Compiler:

Environment Variable	Description
IFORTCFG	Specifies a configuration file that the compiler should use instead of the default configuration file. By default, the compiler uses the default configuration file (ifort.cfg) from the same directory where the compiler executable resides. **NOTE.** On Windows* operating systems, this environment variable cannot be set from the IDE.
INTEL_LICENSE_FILE	Specifies the location of the product license file.
PATH	Specifies the directory path for the compiler executable files.
TMP, TMPDIR, TEMP	Specifies the directory in which to store temporary files. See Temporary Files Created by the Compiler or Linker. **NOTE.** On Windows operating systems, this environment variable cannot be set from the IDE.
FPATH (Linux* OS and Mac OS* X)	The path for include and module files.

Environment Variable	Description
GCCROOT (Linux OS and Mac OS X)	Specifies the location of the gcc binaries. Set this variable only when the compiler cannot locate the gcc binaries when using the -gcc-name option.
GXX_INCLUDE (Linux OS and Mac OS X)	The location of the gcc headers. Set this variable to specify the locations of the GCC installed files when the compiler does not find the needed values as specified by the use of -gcc-name=*directory-name*/gcc.
GXX_ROOT (Linux OS and Mac OS X)	The location of the gcc binaries. Set this variable to specify the locations of the GCC installed files when the compiler does not find the needed values as specified by the use of -gcc-name=*directory-name*/gcc.
LIBRARY_PATH (Linux OS and Mac OS X)	The path for libraries to be used during the link phase.
LD_LIBRARY_PATH (Linux OS)	The path for shared (.so) library files.
DYLD_LIBRARY_PATH (Mac OS X)	The path for dynamic libraries.
INCLUDE (Windows OS)	Specifies the directory path for the include files (files included by an INCLUDE statement, #include files, RC INCLUDE files, and module files referenced by a USE statement).
LIB (Windows OS)	Specifies the directory path for .LIB (library) files, which the linker links in. If the LIB environment variable is not set, the linker looks for .LIB files in the current directory.

Additionally, there are a number of run-time environment variables that you can set. For a list of environment variables recognized at run time and information on setting and viewing environment variables, see Setting Run-Time Environment Variables.

You can use the SET command at the command prompt to set environment variables. Depending on your operating system, there are additional ways to set environment variables.

Setting Environment Variables (Linux OS and Mac OS X)

You can set environment variables by using the `ifortvars.csh` and `ifortvars.sh` files to set several at a time. The files are found in the product's `bin` directory. See Using the ifortvars File to Specify Location of Components.

Within the C Shell, use the setenv command to set an environment variable:

```
setenv FORT9 /usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the C shell, use the `unsetenv` command.

```
unsetenv FORT9
```

Within the Bourne* shell (sh), the Korn shell (ksh), and the bash shell, use the export command and assignment command to set the environment variable:

```
export FORT9
FORT9=/usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the Bourne* shell, the Korn shell, or the bash shell, use the unset command:

```
unset FORT9
```

Setting Environment Variables (Windows OS)

Certain environment variables specifying path, library, and include directories can be defined in the IDE on a per user basis using Tools>Options... from the menu bar.

Additionally, you can set the environment variables needed by Intel Fortran using the `ifortvars.bat` file. See Using the ifortvars File to Specify Location of Components.

NOTE. If you specify `devenv/useenv` on the command line to start the IDE, the IDE uses the PATH, INCLUDE, and LIB environment variables defined for that command line when performing a build. It uses these values instead of the values defined using Tool>Options.

For more information on the `devenv` command, see the `devenv` description in the Microsoft Visual Studio* documentation.

During installation, the Intel Fortran compiler may modify certain system-wide environment variables, depending on your installation choices. (For more information, see the install.htm file.)

To view or change these environment variable settings, do the following:

On Windows* 2000, Windows NT* 4, or Windows XP* operating systems:

1. Log into an account with Administrator privilege.
2. Open the Control panel.
3. Click System.
4. On Windows 2000 and Windows XP systems: Click the Advanced tab and then click the Environment Variables button. On Windows NT 4 systems: Click the Environment tab.
5. View or change the displayed environment variables.
6. To have any environment variable changes take effect immediately, click Apply.
7. Click OK.

NOTE. Changing system-wide environment variables affects command line builds (those done without IDE involvement), but not builds done through the IDE. IDE builds are managed by the environment variables set in the IDE Using Tools>Options. An exception to this is an IDE build (`devenv`) done from the command line that specifies the `/useenv` option. In this case, the IDE uses the PATH, INCLUDE, and LIB environment variables defined for that command line.

You can set an environment variable from within a program by calling the SETENVQQ routine. For example:

```
USE IFPORT
 LOGICAL(4) success
 success = SETENVQQ("PATH=c:\mydir\tmp")
 success = &
 SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
```

Setting Run-Time Environment Variables

The Intel® Fortran run-time system recognizes a number of environment variables. These variables can be used to customize run-time diagnostic error reporting, allow program continuation under certain conditions, disable the display of certain dialog boxes under certain conditions, and allow just-in-time debugging. For a list of run-time environment variables used by OpenMP*, see OpenMP Environment Variables in Optimizing Applications.

For information on setting compile time environment variables, see Setting Compile-Time Environment Variables.

The run-time environment variables are:

- `decfort_dump_flag`

If this variable is set to Y or y, a core dump will be taken when any severe Intel Fortran run-time error occurs.

- `F_UFMTENDIAN`

  This variable specifies the numbers of the units to be used for little-endian-to-big-endian conversion purposes. See Environment `Variable F_UFMTENDIAN` Method.

- `FOR_FMT_TERMINATOR`

  This variable specifies the numbers of the units to have a specific record terminator. See Record Types.

- `FOR_ACCEPT`

  The ACCEPT statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the `FOR_ACCEPT` environment variable. If `FOR_ACCEPT` is *`not`* defined, the code `ACCEPT f,iolist` reads from `CONIN$` (standard input). If `FOR_ACCEPT` is defined (as a file name optionally containing a path), the specified file would be read.

- `FOR_DEBUGGER_IS_PRESENT`

  This variable tells the Fortran run-time library that your program is executing under a debugger. If set to True, it generates debug exceptions whenever severe or continuous errors are detected. Under normal conditions you don't need to set this variable on Windows systems, as this information can be extracted from the operating system. On Linux* OS and Mac OS* X, you will need to set this variable if you want debug exceptions. Setting this variable to True when your program is *not* executing under a debugger will cause unpredictable behavior.

- `FOR_DEFAULT_PRINT_DEVICE` (Windows* OS only)

  This variable lets you specify the print device other than the default print device PRN (LPT1) for files closed (`CLOSE` statement) with the `DISPOSE='PRINT'` specifier. To specify a different print device for the file associated with the `CLOSE` statement `DISPOSE='PRINT'` specifier, set `FOR_DEFAULT_PRINT_DEVICE` to any legal DOS print device before executing the program.

- `FOR_DIAGNOSTIC_LOG_FILE`

  If this variable is set to the name of a file, diagnostic output is written to the specified file.

  The Fortran run-time system attempts to open that file (append output) and write the error information (ASCII text) to the file.

  The setting of `FOR_DIAGNOSTIC_LOG_FILE` is independent of `FOR_DISABLE_DIAGNOSTIC_DISPLAY`, so you can disable the screen display of information but still capture the error information in a file. The text string you assign for the file name is used literally, so you must specify the full name. If the file open fails, no error is reported and the run-time system continues diagnostic processing.

See also Locating Run-Time Errors and Using Traceback Information.

- FOR_DISABLE_DIAGNOSTIC_DISPLAY

  This variable disables the display of all error information. This variable is helpful if you just want to test the error status of your program and do not want the Fortran run-time system to display any information about an abnormal program termination.

  See also Using Traceback Information.

- FOR_DISABLE_STACK_TRACE

  This variable disables the call stack trace information that follows the displayed severe error message text.

  The Fortran run-time error message is displayed whether or not FOR_DISABLE_STACK_TRACE is set to true. If the program is executing under a debugger, the automatic output of the stack trace information by the Fortran library will be disabled to reduce noise. You should use the debugger's stack trace facility if you want to view the stack trace.

  See also Locating Run-Time Errors and Using Traceback Information.

- FOR_IGNORE_EXCEPTIONS

  This variable disables the default run-time exception handling, for example, to allow just-in-time debugging. The run-time system exception handler returns EXCEPTION_CONTINUE_SEARCH to the operating system, which looks for other handlers to service the exception.

- FOR_NOERROR_DIALOGS

  This variable disables the display of dialog boxes when certain exceptions or errors occur. This is useful when running many test programs in batch mode to prevent a failure from stopping execution of the entire test stream.

- FOR_PRINT

  Neither the PRINT statement nor a WRITE statement with an asterisk (*) in place of a unit number includes an explicit logical unit number. Instead, both use an implicit internal logical unit number and the FOR_PRINT environment variable. If FOR_PRINT is *not* defined, the code PRINT f,iolist or WRITE (*,f) iolist writes to CONOUT$ (standard output). If FOR_PRINT is defined (as a file name optionally containing a path), the specified file would be written to.

- FOR_READ

  A READ statement that uses an asterisk (*) in place of a unit number does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_READ environment variable. If FOR_READ is *not* defined, the code READ (*,f) iolist or READ f,iolist reads from CONIN$ (standard input). If FOR_READ is defined (as a file name optionally containing a path), the specified file would be read.

- FOR_TYPE

  The TYPE statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_TYPE environment variable. If FOR_TYPE is *not* defined, the code TYPE f,iolist writes to CONOUT$ (standard output). If FOR_TYPE is defined (as a file name optionally containing a path), the specified file would be written to.

- FORT_BUFFERED

  Lets you request that buffered I/O should be used at run time for output of all Fortran I/O units, except those with output to the terminal. This provides a run-time mechanism to support the -assume buffered_io (Linux OS and Mac OS X) or /assume:buffered_io (Windows OS) compiler option.

- FORT_CONVERT*n*

  Lets you specify the data format for an unformatted file associated with a particular unit number (*n*), as described in Methods of Specifying the Data Format.

- FORT_CONVERT.*ext* and FORT_CONVERT_*ext*

  Lets you specify the data format for unformatted files with a particular file extension suffix (ext), as described in Methods of Specifying the Data Format.

- FORT_FMT_RECL

  Lets you specify the default record length (normally 132 bytes) for formatted files.

- FORT_UFMT_RECL

  Lets you specify the default record length (normally 2040 bytes) for unformatted files.

- FORT*n*

  Lets you specify the file name for a particular unit number *n*, when a file name is not specified in the OPEN statement or an implicit OPEN is used, and the compiler option -fpscomp filesfromcmd (Linux OS and Mac OS X) or /fpscomp:filesfromcmd (Windows OS) was not specified. Preconnected files attached to units 0, 5, and 6 are by default associated with system standard I/O files.

- NLSPATH (Linux OS and Mac OS X only)

  The path for the Intel Fortran run-time error message catalog.

- TBK_ENABLE_VERBOSE_STACK_TRACE

  This variable displays more detailed call stack information in the event of an error.

  The default brief output is usually sufficient to determine where an error occurred. Brief output includes up to twenty stack frames, reported one line per stack frame. For each frame, the image name containing the PC, routine name, line number, and source file are given.

The verbose output, if selected, will provide (in addition to the information in brief output) the exception context record if the error was a machine exception (machine register dump), and for each frame, the return address, frame pointer and stack pointer and possible parameters to the routine. This output can be quite long (but limited to 16K bytes) and use of the environment variable `FOR_DIAGNOSTIC_LOG_FILE` is recommended if you want to capture the output accurately. Most situations should not require the use of verbose output.

The variable `FOR_ENABLE_VERBOSE_STACK_TRACE` is also recognized for compatibility with Compaq* Visual Fortran.

See also Using Traceback Information.

- `TBK_FULL_SRC_FILE_SPEC`

  By default, the traceback output displays only the file name and extension in the source file field. To display complete file name information including the path, set the environment variable `TBK_FULL_SRC_FILE_SPEC` to true.

  The variable `FOR_FULL_SRC_FILE_SPEC` is also recognized for compatibility with Compaq* Visual Fortran.

  See also Using Traceback Information.

- `FORT_TMPDIR`, `TMP`, `TMPDIR`, and `TEMP`

  Specifies an alternate working directory where scratch files are created.

Setting Environment Variables within a Program

You can set a run-time environment variable from within a program by calling the SETENVQQ routine. For example:

```
program ENVVAR
use ifport
LOGICAL(4) res
! Add other data declarations here
! call SETENVQQ as a function
res=SETENVQQ("FOR_IGNORE_EXCEPTIONS=T")
```

Using Compiler Options

7

Compiler Options Overview

A compiler option (also known as a switch) is an optional string of one or more alphanumeric characters preceded by a dash (-) (Linux* OS and Mac OS* X) or a forward slash (/) (Windows*OS).

Some options are on by default when you invoke the compiler.

Depending on your operating system, compiler options are typically specified in the following ways:

- On the compiler command line
- In the IDE, either Xcode (Mac OS X) or Microsoft Visual Studio* (Windows OS)

Most compiler options perform their work at compile time, although a few apply to the generation of extra code used at run time.

For more information about compiler options, see the Compiler Options reference.

For information on the option mapping tool, which shows equivalent options between Windows and Linux OS, see the Option Mapping Tool.

Getting Help on Options

For help, enter `-help [category]` (Linux OS and Mac OS X) or `/help [category]` (Windows) on the command line, which displays brief information about all the command-line options or a specific category of compiler options.

The Compiler Options reference provides a complete description of each compiler option, including the `-help` option.

NOTE. If there are enabling and disabling versions of options on the command line, or two versions of the same option, the last one takes precedence.

Using Multiple ifort Commands

If you compile parts of your program by using multiple ifort commands, options that affect the execution of the program should be used consistently for all compilations, especially if data is shared or passed between procedures. For example:

- The same data alignment needs to be used for data passed or shared by module definitions (such as user-defined structures) or common blocks. Use the same version of the `-align` (Linux OS and Mac OS X) or `/align` (Windows) option for all compilations.
- The program might contain INTEGER, LOGICAL, REAL, or COMPLEX declarations without a kind parameter or size specifier that is passed or shared by module definitions or common blocks. You must consistently use the options that control the size of such numeric data declarations.

Using the OPTIONS Statement to Override Options

You can override some options specified on the command line by using the OPTIONS statement in your Fortran source program. The options specified by the OPTIONS statement affect only the program unit where the statement occurs.

Using the Option Mapping Tool

The Intel compiler's Option Mapping Tool provides an easy method to derive equivalent options between Windows* and Linux*operating systems. If you are a Windows OS developer who is developing an application for Linux OS, you may want to know, for example, the Linux OS equivalent for the `/Oy-` option. Likewise, the Option Mapping Tool provides Windows OS equivalents for Intel compiler options supported on Linux OS.

NOTE. The Compiler Option Mapping Tool does not run on Mac OS* X.

Using the Compiler Option Mapping Tool

You can start the Option Mapping Tool from the command line by:

- invoking the compiler and using the `-map-opts` option
- or, executing the tool directly

NOTE. The Compiler Option Mapping Tool only maps compiler options on the same architecture. It will not, for example, map an option that is specific to the IA-64 architecture to a like option available on the IA-32 architecture or Intel® 64 architecture.

Calling the Option Mapping Tool with the Compiler

If you use the compiler to execute the Option Mapping Tool, the following syntax applies:

```
<compiler command> <map-opts option> <compiler option(s)>
```

Example: Finding the Windows OS equivalent for `-fp`

```
ifort -map-opts -fp
Intel(R) Compiler option mapping tool
mapping Linux OS options to Windows OS for Fortran
'-map-opts' Linux OS option maps to
  --> '-Qmap-opts' option on Windows OS
  --> '-Qmap_opts' option on Windows OS
'-fp' Linux OS option maps to
  --> '-Oy-' option on Windows OS
```

NOTE. Output from the Option Mapping Tool also includes:

- option mapping information (not shown here) for options included in the compiler configuration file
- alternate forms of the options that are supported but may not be documented

Calling the Option Mapping Tool Directly

Use the following syntax to execute the Option Mapping Tool directly from a command line environment where the full path to the `map-opts` executable is known (compiler `bin` directory):

```
map-opts -t<target OS> -l<language> -opts <compiler option(s)>
```

where values for:

- `<target OS> = {l|linux|w|windows}`
- `<language> = {f|fortran|c}`

Example: Finding the Windows equivalent for `-fp`

```
map-opts -tw -lf -opts -fp
Intel(R) Compiler option mapping tool
mapping Linux OS options to Windows OS for Fortran
'-fp' Linux OS option maps to
  --> '-Oy-' option on Windows OS
```

Compiler Directives Related to Options

Some compiler directives and compiler options have the same effect, as shown in the table below. However, compiler directives can be turned on and off throughout a program, while compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

Compiler directives and equivalent command-line compiler options are:

Compiler Directive	Equivalent Command-Line Compiler Option
DECLARE	-warn declarations (Linux* OS and Mac OS* X) /warn:declarations or /4Yd (Windows* OS)
NODECLARE	-warn nodeclarations (Linux OS and Mac OS X) /warn:nodeclarations or /4Nd (Windows OS)
DEFINE *symbol*	-D*name* (Linux OS and Mac OS X) /define:symbol or /D*name* (Windows OS)
FIXEDFORMLINESIZE:*option*	-extend-source [option] (Linux OS and Mac OS X) /extend-source[:*n*] or /4L*n* (Windows OS)
FREEFORM	-free or -nofixed (Linux OS and Mac OS X) /free or /nofixed or /4Yf (Windows OS)
NOFREEFORM	-nofree or -fixed (Linux OS and Mac OS X) /nofree or /fixed or /4Nf (Windows OS)
INTEGER:*option*	-integer_size option (Linux OS and Mac OS X) /integer_size:*option* or /4I*option* (Windows OS)
OBJCOMMENT	/libdir:user (Windows OS)
OPTIMIZE [:*n*]	-O (Linux OS and Mac OS X) or /O (Windows OS) *n* is 0, 1, 2, or 3 for opt levels -O0 through -O3. If *n* is omitted, default is 2.

Compiler Directive	Equivalent Command-Line Compiler Option
NOOPTIMIZE	-O0 (Linux OS and Mac OS X) or /Od (Windows OS)
PACK:*option*	-align [*option*] (Linux OS and Mac OS X) /align[:*n*] or /Zp*n* (Windows OS)
REAL:*option*	-real-size*option* (Linux OS and Mac OS X) /real-size: *option* or /4R*option* (Windows)
STRICT	-warn stderrors with -stand (Linux OS and Mac OS X) /warn:stderrors with /stand:f90 or /4Ys (Windows)
NOSTRICT	-warn nostderrors (Linux OS and Mac OS X) /warn:nostderrors or /4Ns (Windows OS)

NOTE. For Windows OS, the compiler directive names above are specified using the prefix !DEC$ followed by a space; for example: !DEC$ NOSTRICT. The prefix !DEC$ works for both fixed-form and free-form source. You can also use these alternative prefixes for fixed-form source only: cDEC$, CDEC$, *DEC$, cDIR$, CDIR$, *DIR$, and !MS$.

For more information on compiler directives, see Directive Enhanced Compilation.

8 Preprocessing

Using the fpp Preprocessor

If you choose to preprocess your source programs, you can use the preprocessor fpp, which is the preprocessor supplied with the Intel® Fortran Compiler, or the preprocessing directives capability of the Fortran compiler. It is recommended that you use fpp.

The Fortran preprocessor, fpp, is provided as part of the Intel® Fortran product. When you use a preprocessor for Intel Fortran source files, the generated output files are used as input source files by the Compiler.

Preprocessing performs such tasks as preprocessor symbol (macro) substitution, conditional compilation, and file inclusion. Intel Fortran predefined symbols are described in Predefined Preprocessor Symbols.

The Compiler Options reference provides syntactical information on fpp. Additionally, it contains a list of fpp options that are available when fpp is in effect.

Automatic Preprocessing by the Compiler

By default, the preprocessor is not run on files before compilation. However, the Intel Fortran compiler automatically calls fpp when compiling source files that have a filename extension of .fpp, and, on Linux* OS and Mac OS* X, file extensions of .F, .F90, .FOR, .FTN, or .FPP. For example, the following command preprocesses a source file that contains fpp preprocessor directives, then passes the preprocessed file to the compiler and linker:

```
ifort source.fpp
```

If you want to preprocess files that have other Fortran extensions than those listed, you have to explicitly specify the preprocessor with the `-fpp` compiler option.

The fpp preprocessor can process both free- and fixed-form Fortran source files. By default, filenames with the suffix of .F, .f, .for, or .fpp are assumed to be in fixed form. Filenames with a suffix of .F90 or .f90 (or any other suffix not specifically mentioned here) are assumed to be free form. You can use the `-free` (Linux OS and Mac OS X) or /free (Windows* OS) option to specify free form and the `-fixed` (Linux OS and Mac OS X) or `/fixed` (Windows OS) option to explicitly specify fixed form.

The fpp preprocessor recognizes tab format in a source line in fixed form.

Running fpp to Preprocess Files

You can explicitly run fpp in these ways:

- On the `ifort` command line, use the `ifort` command with the `-fpp` (Linux OS and Mac OS X) or `/fpp` (Windows OS) option. By default, the specified files are then compiled and linked. To retain the intermediate (.i or .i90) file, specify the `-save-temps` (Linux OS and Mac OS X) or `/Qsave-temps` (Windows OS) option.
- On the command line, use the fpp command. In this case, the compiler is not invoked. When using the fpp command line, you need to specify the input file and the intermediate (.i or .i90) output file. For more information, type `fpp -help` (Linux OS and Mac OS X) or fpp `/help` (Windows OS) on the command line.
- In the Microsoft Visual Studio* IDE, set the Preprocess Source File option to Yes in the Fortran Preprocessor Option Category. To retain the intermediate files, add `/Qsave-temps` to Additional Options in the Fortran Command Line Category.

fpp has some of the capabilities of the ANSI C preprocessor and supports a similar set of directives. Directives must begin in column 1 of any Fortran source files.Preprocessor directives are not part of the Fortran language and not subject to the rules for Fortran statements. Syntax for directives is based on that of the C preprocessor.

The following lists some common cpp features that are supported by fpp; it also shows common cpp features that are not supported.

Supported cpp features:	**Unsupported cpp features:**
#define, #undef, #ifdef, #ifndef, #if, #elif, #else, #endif, #include, #error, #warning, #line	#pragma, #ident
# (stringsize) and ## (concatenation) operators	spaces or tab characters preceding the initial "#" character
	# followed by empty line
! as negation operator	\ backslash-newline

Unlike cpp, fpp does not merge continued lines into a single line when possible.

You do not usually need to specify preprocessing for Fortran source programs unless your program uses fpp preprocessing commands, such as those listed above.

CAUTION. Using a preprocessor that does not support Fortran can damage your Fortran code, especially with `FORMAT (\\I4)` with cpp changes the meaning of the program because the `double` backslash "`\\`" indicates end-of-record with most C/C++ preprocessors.

fpp Source Files

A source file can contain fpp tokens in the form of :

- fpp directive names. For more information on directives, see Using fpp Directives.
- symbolic names including Fortran keywords. fpp permits the same characters in names as Fortran. For more information on symbolic names, see Using Predefined Preprocessor Symbols.
- constants. Integer, real, double, and quadruple precision real, binary, octal, hexadecimal (including alternate notation), character, and Hollerith constants are allowed.
- special characters, space, tab and newline characters
- comments, including:
  - Fortran language comments. A fixed form source line containing one of the symbols C, c, *, d, or D in the first position is considered a comment line. The ! symbol is interpreted as the beginning of a comment extending to the end of the line except when the "!" occurs within a constant-expression in a #if or #elif directive. Within such comments, macro expansions are not performed, but they can be switched on by `-f-com=no`.
  - fpp comments between / and */. They are excluded from the output and macro expansions are not performed within these symbols. fpp comments can be nested: for each /* there must be a corresponding */. fpp comments are useful for excluding from the compilation large portions of source instead of commenting every line with a Fortran comment symbol.
  - C++ -like line comments which begin with // (double-slash).

A string that is a token can occupy several lines, but only if its input includes continued line characters using the Fortran continuation character &. fpp will not merge such lines into one line.

Identifiers are always placed on one line by fpp. For example, if an input identifier occupies several lines, it will be merged by fpp into one line.

fpp Output

Output consists of a modified copy of the input, plus lines of the form:

```
#line_number  file_name
```

These are inserted to indicate the original source line number and filename of the output line that follows. Use the fpp option `-P` (Linux OS and Mac OS X) or `/P` (Windows OS) to disable the generation of these lines.

Diagnostics

There are three kinds of fpp diagnostic messages:

- warnings: preprocessing of source code is continued and the fpp return value is 0
- errors: fpp continues preprocessing but sets the return value a nonzero value which is the number of errors
- fatal errors: fpp stops preprocessing and returns a nonzero return value.

The messages produced by fpp are intended to be self-explanatory. The line number and filename where the error occurred are displayed along with the diagnostic on stderr.

Using fpp Directives

All fpp directives start with the number sign (#) as the first character on a line. White space (blank or tab characters) can appear after the initial "#" for indentation.

fpp directives (beginning with the # symbol in the first position of lines) can be placed anywhere in a source code, in particular before a Fortran continuation line. However, fpp directives within a macro call may not be divided among several lines by means of continuation symbols.

fpp directives can be grouped according to their purpose.

Directives for string substitution

fpp contains directives that result in substitutions in a user's program:

Directive	Result
`__FILE__`	replace this string with the input file name (a character string literal)
`__LINE__`	replace this string with the current line number in the input file (an integer constant)

Directive	Result
__DATE__	replace this string with the date that fpp processed the input file (a character string literal in the form `Mmm dd yyyy`)
__TIME__	replace this string with the time that fpp processed the input file (a character string literal in the form `hh:mm:ss`)

Directive for inclusion of external files

There are two forms of file inclusion:

`#include "filename"`

`#include <filename>`

This directive reads in the contents of the named file into this location in the source. The lines read in from the file are processed by fpp just as if they were part of the current file.

When the <*filename*> notation is used, *filename* is only searched for in the standard "include" directories. See the `-I` option and also the `-Y` option for more detail. No additional tokens are allowed on the directive line after the final '"' or ">".

Files are searched for in the following order:

- for `#include "filename"`:
  - in the directory in which the source file resides
  - in the directories specified by the `-I` or `-Y` option
  - in the default directory
- for `#include <filename>`:
  - in the directories specified by the `-I` or `-Y` option
  - in the default directory

Directive for line control

This directive takes the following form:

`#line-number "filename"`

This directive generates line control information for the Fortran compiler. *line-number* is an integer constant that is the line number of the next line. "*filename*" is the name of the file containing the line. If "*filename*" is not given, the current filename is assumed.

Directive for fpp variable and macro definitions

The #define directive, used to define both simple string variables and more complicated macros, takes the two forms.

The first form is the definition of an fpp variable:

```
#define name token-string
```

In the above, occurrences of *name* in the source file will be substituted with *token-string*.

The second form is the definition of an fpp macro.

```
#define name(argument[,argument] ... ) token-string
```

In the above, occurrences of the macro *name* followed by the comma-separated list of actual arguments within parentheses are replaced by token-string with each occurrence of each *argument* in token-string replaced by the token sequence representing the corresponding "actual" argument in the macro call.

An error is produced if the number of macro call arguments is not the same as the number of arguments in the corresponding macro definition. For example, consider this macro definition:

```
#define INTSUB(m, n, o) call mysub(m, n, o)
```

Any use of the macro INTSUB must have three arguments. In macro definitions, spaces between the macro name and the open parenthesis "(" are prohibited to prevent the directive from being interpreted as an fpp variable definition with the rest of the line beginning with the open parenthesis "(" being interpreted as its token-string.

An fpp variable or macro definition can be of any length and is limited only by the newline symbol. It can be defined in multiple lines by continuing it to the next line with the insertion of "\". The occurrence of a newline without a macro-continuation signifies the end of the macro definition.

Example:

```
#define long_macro_name(x,\
   y) x*y
```

The scope of a definition begins from the #define and encloses all the source lines (and source lines from #include files) to the end of the current file, except for:

- files included by Fortran INCLUDE statements

- fpp and Fortran comments
- Fortran IMPLICIT statements that specify a single letter
- Fortran FORMAT statements
- numeric, typeless, and character constants

Directive for undefining a macro

This directive takes the following form:

```
#undef name
```

This directive removes any definition for *name* (produced by -D options, #define directives, or by default). No additional tokens are permitted on the directive line after *name*.

If *name* has not been defined earlier, then the #undef directive has no effect.

Directive for macro expansion

If, during expansion of a macro, the column width of a line exceeds column 72 (for fixed format) or column 132 (for free format), fpp inserts appropriate Fortran continuation lines.

For fixed format, there is a limit on macro expansions in label fields (positions 1-5):

- a macro call (together with possible arguments) should not extend beyond column 5
- a macro call whose name begins with one of the Fortran comment symbols is considered to be part of a comment
- a macro expansion may produce text extending beyond column 5. In this case, a warning will be issued

In fixed format, when the fpp `-Xw` option has been specified, an ambiguity may occur if a macro call occurs in a statement position and a macro name begins or coincides with a Fortran keyword. For example, consider the following:

```
#define callp(x)   call f(x)
  call p(0)
```

fpp cannot determine how to interpret the "call p" token sequence above. It could be considered as a macro name. The current implementation does the following:

- the longer identifier is chosen (callp in this case)
- from this identifier the longest macro name or keyword is extracted

- if a macro name has been extracted a macro expansion is performed. If the name begins with some keyword, fpp issues an appropriate warning
- the rest of the identifier is considered as a whole identifier

In the previous example, the macro expansion is performed and the following warning is produced:

```
warning: possibly incorrect substitution of macro callp
```

This situation appears only when preprocessing a fixed format source code and when the space symbol is not interpreted as a token delimiter.

In the following case, a macro name coincides with a beginning of a keyword:

```
 #define INT  INTEGER*8
              INTEGER k
```

The INTEGER keyword will be found earlier than the INT macro name. There will be no warning when preprocessing such a macro definition.

Directives for conditional selection of source text

There are three forms of conditional selection of source text.

Form 1:

```
#if condition_1
                block_1
            #elif condition_2
                block_2
            #elif ...
            #else
                 block_n
            #endif
```

Form 2:

```
          #ifdefname
                block_1
            #elif condition
                block_2
            #elif ...
            #else
                block_n
            #endif
```

Form 3:

```
#ifndef name
        block_1
   #elif condition
        block_2
   #elif ...
   #else
        block_n
   #endif
```

The `elif` and `else` parts are optional in all three forms. There may be more than one `elif` part in each form.

Conditional expressions

condition_1, *condition_2*, etc. are logical expressions involving fpp constants, macros, and intrinsic functions. The following items are permitted:

- C language operations: <, >, ==, !=, >=, <=, +, -, /, *, %, <<, >>, &, ~, |, &&, || They are interpreted by fpp in accordance to the C language semantics (this facility is provided for compatibility with "old" Fortran programs using cpp)
- Fortran language operations: .AND., .OR., .NEQV., .XOR., .EQV., .NOT., .GT., .LT., .LE., .GE., .NE., .EQ., ** (power).
- Fortran logical constants: .TRUE. , .FALSE.
- the fpp intrinsic function "`defined`": `defined(name)` or `defined name` which returns .TRUE. if name is defined as an fpp variable or a macro or returns .FALSE. if the name is not defined

`#ifdef` is a shorthand for `#if defined(name)` and `#ifndef` is a shorthand for `#if .not. defined(name)`.

Only these items, integer constants, and names can be used within a constant-expression. A name that has not been defined with the `-D` option, a `#define` directive, or by default, has a value of 0. The C operation `!=` (not equal) can be used in `#if` or `#elif` directive, but not in the `#define` directive, where the symbol `!` is considered as the Fortran comment symbol by default.

Conditional constructs

The following table summarizes conditional constructs.

Construct	Result
#if *condition*	Subsequent lines up to the matching #else, #elif, or #endif directive appear in the output only if *condition* evaluates to .TRUE. .
#ifdef *name*	Subsequent lines up to the matching #else, #elif, or #endif appear in the output only if name has been defined, either by a #define directive or by the -D option, with no intervening #undef directive. No additional tokens are permitted on the directive line after *name*.
#ifndef *name*	Subsequent lines up to the matching #else, #elif, or #endif appear in the output only if *name* has not been defined, or if its definition has been removed with an #undef directive. No additional tokens are permitted on the directive line after *name*.
#elif *condition*	Subsequent lines up to the matching #else, #elif, or #endif appear in the output only if all of the following occur: • The condition in the preceding #if directive evaluates to .FALSE. or the name in the preceding #ifdef directive is not defined, or the name in the preceding #ifndef directive is defined. • The conditions in all of the preceding #elif directives evaluate to .FALSE. • The condition in the current #elif evaluates to .TRUE. Any condition allowed in an #if directive is allowed in an #elif directive. Any number of #elif directives may appear between an #if, #ifdef, or #ifndef directive and a matching #else or #endif directive.
#else	Subsequent lines up to the matching #endif appear in the output only if all of the following occur: • The condition in the preceding #if directive evaluates to .FALSE. or the name in the preceding #ifdef directive is not defined, or the name in the preceding #ifndef directive is defined. • The conditions in all of the preceding #elif directives evaluate to .FALSE.
#endif	End a section of lines begun by one of the conditional directives #if, #ifdef, or #ifndef. Each such directive must have a matching #endif.

Using Predefined Preprocessor Symbols

Preprocessor symbols (macros) let you substitute values in a program before it is compiled. The substitution is performed in the preprocessing phase.

Some preprocessor symbols are predefined by the compiler system and are available to compiler directives and to fpp. If you want to use others, you need to specify them on the command line.

You can use the `-D` (Linux* OS and Mac OS* X) or `/D` (Windows* OS) option to define the symbol names to be used during preprocessing. This option performs the same function as the `#define` preprocessor directive.

For more information, see the following topic:

- D compiler option

Preprocessing with fpp replaces every occurrence of the defined symbol name with the specified value. Preprocessing compiler directives only allow IF and IF DEFINED.

If you want to disable symbol replacement (also known as macro expansion) during the preprocessor step, you can specify the following: `-fpp:"-macro=no"` (Linux OS and Mac OS X or `/fpp:"/macro=no"` (Windows OS).

Disabling preprocessor symbol replacement is useful for running fpp to perform conditional compilation (using #ifdef, etc.) without replacement.

You can use the `-U` (Linux OS and Mac OS X) or `/U` (Windows OS) option to suppress an automatic definition of a preprocessor symbol. This option suppresses any symbol definition currently in effect for the specified *`name`*. This option performs the same function as an #undef preprocessor directive.

For more information, see the following topic:

- U compiler option

Windows OS:

The following information applies to Windows operating systems.

In addition to specifying preprocessor symbols on the command line, you can also specify them in the Visual Studio* integrated development environment (IDE). To do this, select Project>Properties and use the Preprocessor Definitions item in the General Options or Preprocessor Options category.

The following preprocessor symbols are available:

Predefined Symbol Name and Value	Conditions When this Symbol is Defined
__INTEL_COMPILER=1110	Identifies the Intel Fortran compiler
__INTEL_COMPILER_BUILD_DATE=*YYYYMMDD*	Identifies the Intel Fortran compiler build date
_DLL=1	Only if `/libs:dll`, `/MDs`, `/MD`, `/dll`, or `/LD` is specified, but *not* when `/libs:static` is specified
_MT=1	Only if `/threads` or `/MT` is specified
_M_IX86=*n*00	Only for systems based on IA-32 architecture; *n* is the number specified for `/G` (for example, `_M_IX86=700` for `/G7`)
_M_IA64=64*n*00	Only for systems based on IA-64 architecture; *n* is the number specified for `/G` (for example, `_M_IA64=64200` for `/G1`)
_M_X64	Only for systems based on Intel® 64 architecture. For use in conditionalizing applications for the Intel® 64 platform.
_M_AMD64	Only for systems based on Intel® 64 architecture. This symbol is set by default.
_OPENMP=200805	Valid when OpenMP processing has been requested (that is, when `/Qopenmp` is specified) Takes the form *YYYYMM* where *YYYY* is the year and *MM* is the month of the OpenMP Fortran specification supported. This symbol can be used in both fpp and the Fortran compiler conditional compilations.
_PGO_INSTRUMENT	Defined if `/Qprof_gen` is specified
_WIN32	Always defined
_WIN64	Only for systems based on Intel® 64 architecture and systems based on IA-64 architecture
_VF_VER=1110	Valid when Compaq* Visual Fortran-compatible compile commands (df or f90) are used

When using the non-native IA-64 architecture based compiler, platform-specific symbols are set for the target platform of the executable, not for the system in use.

Linux OS and Mac OS X:

The following information applies to Linux OS and Mac OS X systems.

Symbol Name	Default	Architecture (IA-32, Intel® 64, IA-64)	Description
__INTEL_COMPILER=*n*	On, *n*=1110	All	Identifies the Intel Fortran Compiler
__INTEL_COMPILER_BUILD_DATE =*YYYYMMDD*		All	Identifies the Intel Fortran Compiler build date
__linux__ (Linux only) __linux (Linux only) __gnu_linux__ (Linux only) linux (Linux only) __unix__ (Linux only) __unix (Linux only) unix (Linux only) __ELF__ (Linux only)		All	Defined at the start of compilation
__APPLE__ (Mac OS X only) __MACH__ (Mac OS X only)		IA-32	Defined at the start of compilation
__i386__ __i386 i386		IA-32	Identifies the architecture for the target hardware for which programs are being compiled

Symbol Name	Default	Architecture (IA-32, Intel® 64, IA-64)	Description
__ia64__ (Linux only) __ia64 (Linux only)		IA-64	Identifies the architecture for the target hardware for which programs are being compiled
__x86_64 __x86_64__		Intel® 64	Identifies the architecture for the target hardware for which programs are being compiled.
_OPENMP=*n*	*n*=200805	All	Takes the form *YYYYMM*, where *YYYY* is the year and *MM* is the month of the OpenMP Fortran specification supported. This preprocessor symbol can be used in both fpp and the Fortran compiler conditional compilation. It is available only when -openmp is specified.
_PGO_INSTRUMENT	Off	All	Defined when -prof-gen is specified.
__PIC__ __pic__	Off (Linux OS), On (Mac OS X)	All	Set if the code was requested to be compiled as position independent code. On Mac OS X, these symbols are always set.

Using Configuration Files and Response Files

9

Configuration Files and Response Files Overview

Configuration files and response files let you enter command-line options in a file. Both types of files provide the following benefits:

- Decrease the time you spend entering command-line options
- Ensure consistency of often used commands

See these topics:

- Using Configuration Files
- Using Response Files

Using Configuration Files

Configuration files are automatically processed every time you run the compiler. You can insert any valid command-line options into the configuration file. The compiler processes options in the configuration file in the order in which they appear, followed by the command-line options that you specify when you invoke the compiler.

NOTE. Options in the configuration file are executed every time you run the compiler. If you have varying option requirements for different projects, use response files.

By default, a configuration file named `ifort.cfg` is used. This file resides in the same directory where the compiler executable resides. However, if you want the compiler to use another configuration file in a different location, you can use the `IFORTCFG` environment variable to assign the directory and file name for the configuration file.

Sample Configuration Files

Examples that follow illustrate sample configuration files. The pound (`#`) character indicates that the rest of the line is a comment.

Linux* OS and Mac OS* X Example:

```
## Example ifort.cfg file
##
## Define preprocessor macro MY_PROJECT.
-DMY_PROJECT
##
## Set extended-length source lines.
-extend_source
##
## Set maximum floating-point significand precision.
-pc80
##
```

Windows* OS Example:

```
#
# Sample ifort.cfg file
## Define preprocessor macro MY_PROJECT
/DMY_PROJECT

## Set extended-length source lines.
/extend_source
##
## Set maximum floating-point significand precision.
/Qpc80
##

## Additional directories to be searched for include
## files, before the default.

/Ic:\project\include

## Use the static, multithreaded run-time library.

/MT
```

Using Response Files

You can use response files to:

- Specify options used during particular compilations for particular projects
- Save this information in individual files

Unlike configuration files, which are automatically processed every time you run the compiler, response files must be invoked as an option on the command line. If you create a response file but do not specify it on the command line, it will not be invoked.

Options specified in a response file are inserted in the command line at the point where the response file is invoked.

You can place any number of options or filenames on a line in the response file. Several response files can be referenced in the same command line.

The syntax for using response files is:

```
ifort @responsefile1 [@responsefile2 ... ]
```

NOTE. An "at" sign (@) must precede the name of the response file on the command line.

Debugging 10

Debugging Fortran Programs

Depending on your operating system and your architecture platform, several debuggers may be available to you.

You can use the debugger provided by your operating system. On Linux* OS and Mac OS* X, this debugger is gdb. On Windows* OS, the debugger is the Microsoft integrated debugger.

On Linux OS and Mac OS X systems, you can also use the Intel® Debugger to debug Intel® Fortran programs.

For more information on IDB, see the Intel Debugger online documentation.

NOTE. On Linux OS and Mac OS X systems, use of the IDB debugger is recommended.

Preparing Your Program for Debugging

This section describes preparing your program for debugging.

Preparing for Debugging using the Command Line

To prepare your program for debugging when using the command line (ifort command):

1. Correct any compilation and linker errors.
2. In a command window, (such as the Fortran command window available from the Intel Fortran program folder), compile and link the program with full debug information and no optimization:

   `ifort -g file.f90` (Linux OS and Mac OS X)

   `ifort /debug:full file.f90` (Windows OS)

On Linux OS and Mac OS X, specify the `-g` compiler option to create unoptimized code and provide the symbol table and traceback information needed for symbolic debugging. (The `-notraceback` option cancels the traceback information.)

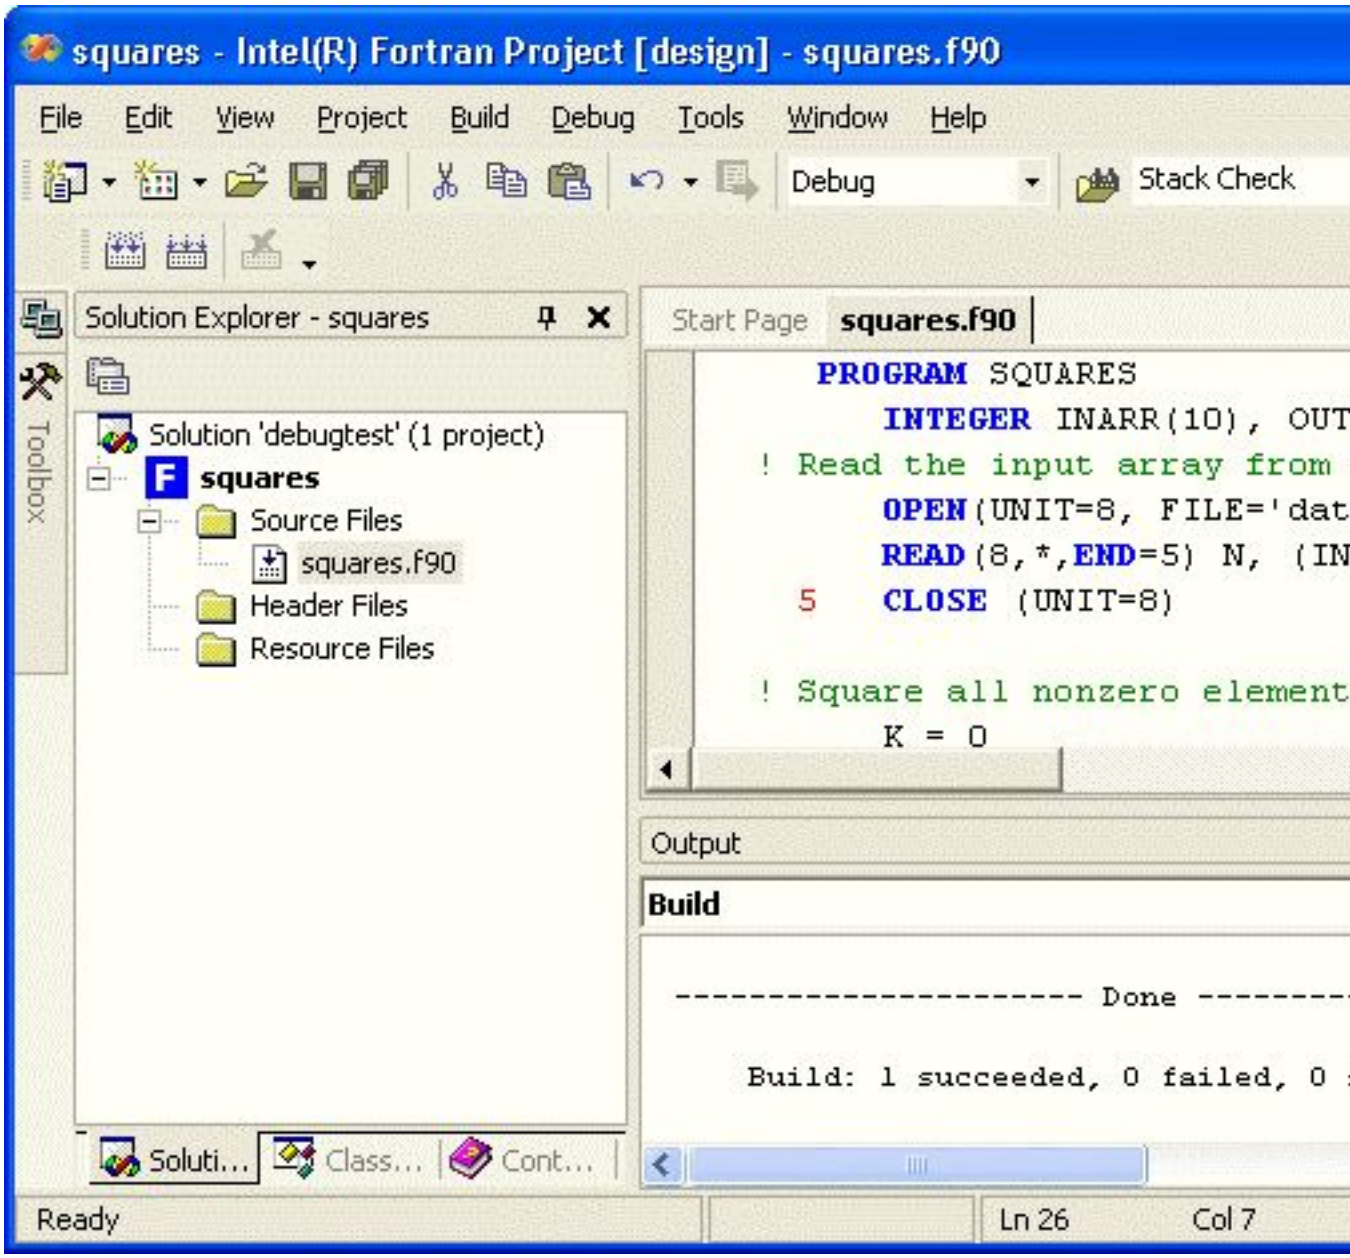
On Windows OS, specify the `/debug:full` compiler option to produce full debugging information. It produces symbol table information needed for full symbolic debugging of unoptimized code and global symbol information needed for linking.

Preparing for Debugging using Microsoft Visual Studio*

The following applies to Windows* operating systems only.

To prepare your program for debugging when using the integrated development environment (IDE):

1. Start the IDE (select the appropriate version of Microsoft Visual Studio in the program folder).
2. Open the appropriate solution (using the Solution menu, either Open Solution or Recent Projects).
3. Open the Solution Explorer View.
4. To view the source file to be debugged, double-click on the file name. The screen resembles the following:



squares - Intel(R) Fortran Project [design] - squares.f90

5. In the Build menu, select Configuration Manager and select the Debug configuration.
6. To check your project settings for compiling and linking, select the project name in the Solution Explorer. Now, in the Project menu, select Properties, then click the Fortran folder in the left pane. Similarly, to check the debug options set for your project (such as command arguments or working directory), click the Debugging folder in the Property Pages dialog box.
7. To build your application, select Build>Build Solution.
8. Eliminate any compiler diagnostic messages using the text editor to resolve problems detected in the source code and recompile if needed.
9. Set breakpoints in the source file and debug the program.

Locating Unaligned Data

Unaligned data can slow program execution. You should determine the cause of the unaligned data, fix the source code (if necessary), and recompile and relink the program.

If your program encounters unaligned data at run time, to make it easier to debug the program, you should recompile and relink with the `-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS) option to generate sufficient table information and debug unoptimized code.

For more information on data alignment, see the following:

Understanding Data Alignment

Setting Data Type and Alignment

Debugging a Program that Encounters a Signal or Exception

If your program encounters a signal (exception) at run time, you may want to recompile and relink with certain command-line options before debugging the cause. The following will make it easier to debug the program:

- Use the `-fpe`*n* (Linux OS and Mac OS X) or `/fpe:n` (Windows OS) option to control the handling of floating point exceptions.
- As with other debugging tasks, use the `-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS) compiler option to generate sufficient symbol table information and debug unoptimized code.

Debugging an Exception in the Microsoft Debugger

The following applies to Windows* operating systems.

You can request that the program always stop when a certain type of exception occurs. Certain exceptions are caught by default by the Intel Visual Fortran run-time library, so your program stops in the run-time library code. In most cases, you want the program to stop in your program's source code instead .

To change how an exception is handled in the Microsoft debugger:

1. In the Debug menu, select Exceptions.
2. View the displayed exceptions.
3. Select Windows Exceptions. Select each type of exception to be changed and change its handling using the radio buttons.
4. Start program execution using Start in the Debug menu.
5. When the exception occurs, you can now view the source line being executed, examine current variable values, execute the next instruction, and so on to help you better understand that part of your program.
6. After you locate the error and correct the program, consider whether you want to reset the appropriate type of exception to "Use Parent Setting" before you debug the program again.

For machine exceptions, you can use the just-in-time debugging feature to debug your programs as they run outside of the visual development environment. To do this, set the following items:

- In Tools>Options, select Native in the Debugging Just-In Time category.
- Set the `FOR_IGNORE_EXCEPTIONS` environment variable to `TRUE`.

Debugging and Optimizations

This topic describes the relationship between various command-line options that control debugging and optimizing.

Whenever you enable debugging with `-g` (Linux* OS and Mac OS* X) or `/debug:full` (Windows* OS), you disable optimizations. You can override this behavior by explicitly specifying compiler options for optimizations on the command line.

The following summarizes commonly used options for debugging and for optimization.

`-O0` (Linux OS and Mac OS X) or `/Od` (Windows* OS)	Disables optimizations so you can debug your program before any optimization is attempted. This is the default behavior when debugging. On Linux OS and Mac OS X, `-fno-omit-frame-pointer` is set if option -O0 (or -g) is specified. For more information, see the following topic: • `-O0` (Linux OS and Mac OS X) or `/Od` (Windows OS) compiler option
`-O1` or `/O1` `-O2` or `/O2 -O3` or `/O3`	Specifies the code optimization level for applications. If you use any of these options, it is recommended that you use `-debug extended` when debugging. For more information, see the following topic: • `-O1`, `-O2`, `-O3` (Linux OS and Mac OS X) or `/O` (Windows OS) compiler option
`-g` or `/debug:full`	Generates symbolic debugging information and line numbers in the object code for use by the source-level debuggers. Turns off `-O2` (Linux OS and Mac OS X) or `/O2` (Windows) and makes `-O0` (Linux OS and Mac OS X) or `/Od` (Windows OS)the default. The exception to this is if `-O2`, `-O1` or `-O3` (Linux OS and Mac OS X) or `/O2`, `/O1` or `/O3` (Windows OS) is explicitly specified in the command line. For more information, see the following topic: • `-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS) compiler option
`-debug extended` (Linux OS and Mac OS X)	Specifies settings that enhance debugging. For more information, see the following topic: • `-debug extended` (Linux OS and Mac OS X)
`-fp` or `/Oy-` (IA-32 architecture only)	Disables the ebp register in optimizations and sets the ebp register to be used as the frame pointer. For more information, see the following topic: • `-fp` (Linux OS and Mac OS X) or `/Oy` (Windows OS) compiler option

`-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS)	Causes the compiler to generate extra information in the object file, which allows a symbolic stack traceback. For more information, see the following topic: • `-traceback` compiler option

Combining Optimization and Debugging

The compiler lets you generate code to support symbolic debugging when one of the `O1`, `O2`, or `O3` optimization options is specified on the command line along with `-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS); this produces symbolic debug information in the object file.

Note that if you specify an `O1`, `O2`, or `O3` option with the -g or `/debug:full` option, some of the debugging information returned may be inaccurate as a side-effect of optimization. To counter this on Linux OS and Mac OS X, you should also specify the `-debug extended` option.

It is best to make your optimization and/or debugging choices explicit:

- If you need to debug your program excluding any optimization effect, use the `-O0` (Linux OS and Mac OS X) or `/Od` (Windows OS) option, which turns off all the optimizations.
- If you need to debug your program with optimizations enabled, then you can specify the `O1`, `O2`, or `O3` option on the command line along with `debug extended`.

NOTE. When no optimization level is specified, the `-g` or `/debug:full` option slows program execution; this is because this option turns on `-O0` or `/Od`, which causes the slowdown. However, if, for example, both `-O2` (Linux OS and Mac OS X) or `/O2` (Windows OS) and `-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS) are specified, the code should not experience much of a slowdown.

Refer to the table below for the summary of the effects of using the `-g` or `/debug:full` option with the optimization options.

These options	Produce these results
`-g` (Linux OS and Mac OS X) or `/debug:full` (Windows OS)	Debugging information produced, `-O0` or `/Od` enabled (meaning optimizations are disabled). For Linux OS and Mac OS X, `-fp` is also enabled for compilations targeted for IA-32 architecture.

These options	Produce these results
`-g -O1` (Linux OS and Mac OS X) or `/debug:full /O1` (Windows*)	Debugging information produced, O1 optimizations enabled.
`-g -O2` (Linux OS and Mac OS X) or `/debug:full /O2` (Windows OS)	Debugging information produced, O2 optimizations enabled.
`-g -O2` (Linux OS and Mac OS X) or `/debug:full /O2 /Oy-` (Windows OS)	Debugging information produced, O2 optimizations enabled; for Windows OS using IA-32 architecture, `/Oy` disabled.
`-g -O3 -fp` (Linux OS and Mac OS X) or `/debug:full /O3` (Windows OS)	Debugging information produced, O3 optimizations enabled; for Linux OS, `-fp` enabled for compilations targeted for IA-32 architecture.

NOTE. Even the use of `debug extended` with optimized programs may not allow you to examine all variables or to set breaks at all lines, due to code movement or removal during the optimization process

Debugging Multithreaded Programs

The debugging of multithreaded program discussed in this topic applies to both the OpenMP* Fortran API and the Intel Fortran parallel compiler directives. When a program uses parallel decomposition directives, you must take into consideration that the bug might be caused either by an incorrect program statement or it might be caused by an incorrect parallel decomposition directive. In either case, the program to be debugged can be executed by multiple threads simultaneously.

To determine the correctness of and debug multithreaded programs, you can use the following:

- For Linux OS and Mac OS X systems, Intel® Debugger (IDB) or GDB
- For Windows operating systems, Microsoft Visual Studio* Debugger

- Intel Fortran Compiler debugging options and methods; in particular, `-debug` and `-traceback` (Linux OS and Mac OS X) or `/debug` and `/traceback` (Windows OS)

Data and I/O

11

Data Representation

Data Representation Overview

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte). For information on using nonnative big endian and VAX* floating-point formats, see Supported Native and Nonnative Numeric Formats.

The symbol :A in any figure specifies the address of the byte containing bit 0, which is the starting address of the represented data element.

The following table lists the intrinsic data types used by Intel® Fortran, the storage required, and valid ranges. For information on declaring Fortran intrinsic data types, see Type Declaration Statements. For example, the declaration INTEGER(4) is the same as INTEGER(KIND=4) and INTEGER*4.

Table 21: Fortran Data Types and Storage

Data Type	Storage	Description
BYTE INTEGER(1)	1 byte (8 bits)	A BYTE declaration is a signed integer data type equivalent to INTEGER(1).
INTEGER	See INTEGER(2), INTEGER(4), and INTEGER(8)	Signed integer, either INTEGER(2), INTEGER(4), or INTEGER(8). The size is controlled by the `-integer-size` (Linux* OS and Mac OS* X) or `/integer-size` (Windows* OS) compiler option.
INTEGER(1)	1 byte (8 bits)	Signed integer value from -128 to 127.
INTEGER(2)	2 bytes (16 bits)	Signed integer value from -32,768 to 32,767.
INTEGER(4)	4 bytes (32 bits)	Signed integer value from -2,147,483,648 to 2,147,483,647.

Data Type	Storage	Description
INTEGER(8)	8 bytes (64 bits)	Signed integer value from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.
REAL	See REAL(4), REAL(8) and REAL(16).	Real floating-point values, either REAL(4), REAL(8), or REAL(16). The size is controlled by the `-real-size` (Linux OS and Mac OS X) or `/real-size` (Windows) compiler option.
REAL(4)	4 bytes (32 bits)	Single-precision real floating-point values in IEEE S_floating format ranging from 1.17549435E-38 to 3.40282347E38. Values between 1.17549429E-38 and 1.40129846E-45 are denormalized (subnormal).
REAL(8)	8 bytes (64 bits)	Double-precision real floating-point values in IEEE T_floating format ranging from 2.2250738585072013D-308 to 1.7976931348623158D308. Values between 2.2250738585072008D-308 and 4.9406564584124654D-324 are denormalized (subnormal).
REAL(16)	16 bytes (128 bits)	Extended-precision real floating-point values in IEEE-style X_floating format ranging from 6.475175119438025110924438958227646552499 6Q-4966 to 1.189731495357231765085759326628007016196477Q4932.
COMPLEX	See COMPLEX(4), COMPLEX(8) and COMPLEX(16).	Complex floating-point values in a pair of real and imaginary parts that are either REAL(4), REAL(8), or REAL(16). The size is controlled by the `-real-size` (Linux OS and Mac OS X) or `/real-size` (Windows OS) compiler option.
COMPLEX(4)	8 bytes (64 bits)	Single-precision complex floating-point values in a pair of IEEE S_floating format parts: real and imaginary. The real and imaginary parts each range from 1.17549435E-38 to 3.40282347E38. Values between 1.17549429E-38 and 1.40129846E-45 are denormalized (subnormal).
COMPLEX(8) DOUBLE COMPLEX	16 bytes (128 bits)	Double-precision complex floating-point values in a pair of IEEE T_floating format parts: real and imaginary. The real and imaginary parts each range from 2.2250738585072013D-308

Data Type	Storage	Description
		to 1.7976931348623158D308. Values between 2.2250738585072008D-308 and 4.9406564584124654D-324 are denormalized (subnormal).
COMPLEX(16)	32 bytes (256 bits)	Extended-precision complex floating-point values in a pair of IEEE-style X_floating format parts: real and imaginary. The real and imaginary parts each range from 6.475175119438025110924438958227646552499 6Q-4966 to 1.189731495357231765085759326628007016196477Q4932.
LOGICAL	See LOGICAL(2), LOGICAL(4), and LOGICAL(8).	Logical value, either LOGICAL(2), LOGICAL(4), or LOGICAL(8). The size is controlled by the `-integer-size` (Linux OS and Mac OS X) or `/integer-size` (Windows OS) compiler option.
LOGICAL(1)	1 byte (8 bits)	Logical values .TRUE. or .FALSE.
LOGICAL(2)	2 bytes (16 bits)	Logical values .TRUE. or .FALSE.
LOGICAL(4)	4 bytes (32 bits)	Logical values .TRUE. or .FALSE.
LOGICAL(8)	8 bytes (64 bits)	Logical values .TRUE. or .FALSE.
CHARACTER	1 byte (8 bits) per character	Character data represented by character code convention. Character declarations can be in the form CHARACTER(LEN=*n*) or CHARACTER**n*, where *n* is the number of bytes or *n* is (*) to indicate passed-length format.
HOLLERITH	1 byte (8 bits) per Hollerith character	Hollerith constants.

In addition, you can define binary (bit) constants.

Integer Data Representations

Integer Data Representations Overview

The Fortran numeric environment is flexible, which helps make Fortran a strong language for intensive numerical calculations. The Fortran standard purposely leaves the precision of numeric quantities and the method of rounding numeric results unspecified. This allows Fortran to operate efficiently for diverse applications on diverse systems.

The effect of math computations on integers is straightforward:

- Integers of KIND=1 consist of a maximum positive integer (127), a minimum negative integer (-128), and all integers between them including zero.
- Integers of KIND=2 consist of a maximum positive integer (32,767), a minimum negative integer (-32,768) , and all integers between them including zero.
- Integers of KIND=4 consist of a maximum positive integer (2,147,483,647), a minimum negative integer (-2,147,483,648), and all integers between them including zero.
- Integers of KIND=8 consist of a maximum positive integer (9,223,372,036,854,775,807), a minimum negative integer (-9,223,372,036,854,775,808), and all integers between them including zero.

Operations on integers usually result in other integers within this range. Integer computations that produce values too large or too small to be represented in the desired KIND result in the loss of precision. One arithmetic rule to remember is that integer division results in truncation (for example, 8/3 evaluates to 2).

Integer data lengths can be 1, 2, 4, or 8 bytes in length.

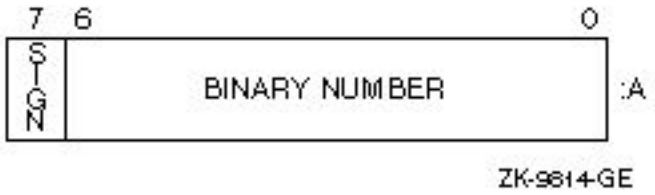
The default data size used for an INTEGER data declaration is INTEGER(4) (same as INTEGER(KIND=4), unless the `-integer-size 16` (Linux* OS and Mac OS* X) or `/integer-size:16` (Windows*OS) or the `-integer-size 64` (Linux OS and Mac OS X) or `/integer-size:64` (Windows OS) option was specified.

Integer data is signed with the sign bit being 0 (zero) for positive numbers and 1 for negative numbers.

INTEGER(KIND=1) Representation

INTEGER(1) values range from -128 to 127 and are stored in 1 byte, as shown below.

Figure 1: INTEGER(1) Data Representation



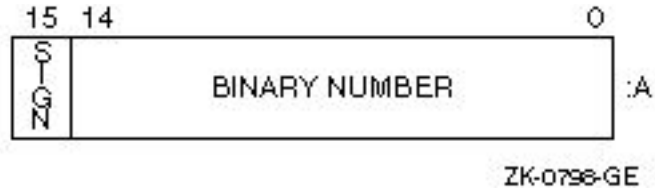
Integers are stored in a two's complement representation. For example:

```
+22 = 16(hex)-7
 = F9(hex)
```

INTEGER(KIND=2) Representation

INTEGER(2) values range from -32,768 to 32,767 and are stored in 2 contiguous bytes, as shown below:

Figure 2: INTEGER(2) Data Representation



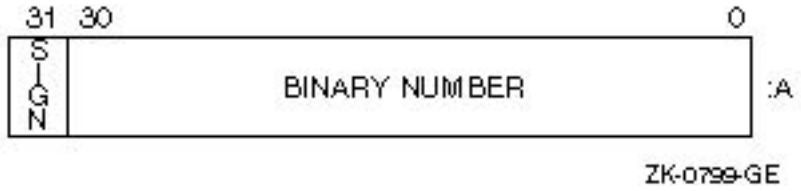
Integers are stored in a two's complement representation. For example:

```
+22 = 0016(hex) -7
 = FFF9(hex)
```

INTEGER(KIND=4) Representation

INTEGER(4) values range from -2,147,483,648 to 2,147,483,647 and are stored in 4 contiguous bytes, as shown below.

Figure 3: INTEGER(4) Data Representation

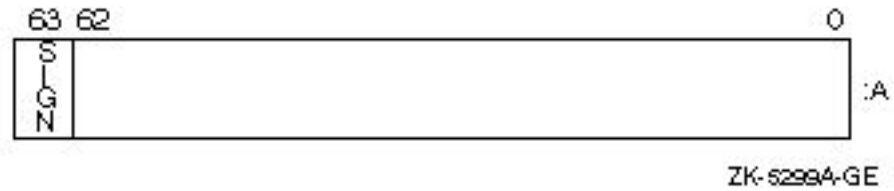


Integers are stored in a two's complement representation.

INTEGER(KIND=8) Representation

INTEGER(8) values range from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807 and are stored in 8 contiguous bytes, as shown below.

Figure 4: INTEGER(8) Data Representation



Integers are stored in a two's complement representation.

Logical Data Representations

Logical data lengths can be 1, 2, 4, or 8 bytes in length.

The default data size used for a LOGICAL data declaration is LOGICAL(4) (same as LOGICAL(KIND=4)), unless `-integer-size 16` or `-integer-size 64` (Linux OS and Mac OS X) or `/integer-size:16` or `/integer-size:64` (Windows OS) was specified.

To improve performance on systems using Intel® 64 architecture and IA-64 architecture, use LOGICAL(4) (or LOGICAL(8)) rather than LOGICAL(2) or LOGICAL(1). On systems using IA-32 architecture, use LOGICAL(4) rather than LOGICAL(8), LOGICAL(2), or LOGICAL(1).

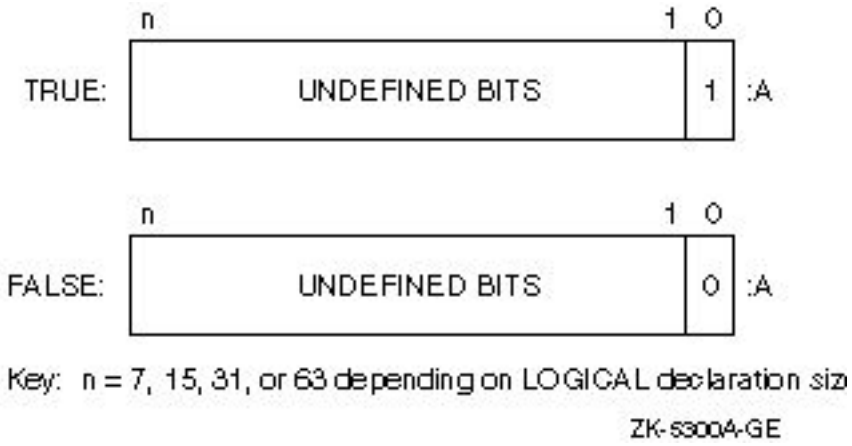
LOGICAL(KIND=1) values are stored in 1 byte. In addition to having logical values .TRUE. and .FALSE., LOGICAL(1) data can also have values in the range -128 to 127. Logical variables can also be interpreted as integer data.

In addition to LOGICAL(1), logical values can also be stored in 2 (LOGICAL(2)), 4 (LOGICAL(4)), or 8 (LOGICAL(8)) contiguous bytes, starting on an arbitrary byte boundary.

If the `-fpscomp nological` (Linux OS and Mac OS X) or `/fpscomp:nological` (Windows OS) compiler option is set (the default), the low-order bit determines whether the logical value is true or false. Specify `logical` instead of `nological` for Microsoft* Fortran PowerStation logical values, where 0 (zero) is false and non-zero values are true.

LOGICAL(1), LOGICAL(2), LOGICAL(4), and LOGICAL(8) data representation (when `nological` is specified) appears below.

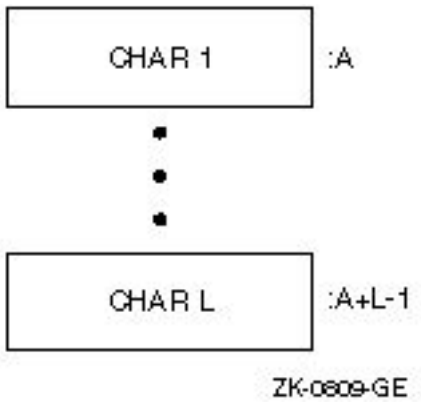
Figure 5: LOGICAL(1), LOGICAL(2), LOGICAL(4), and LOGICAL(8) Data Representations



Character Representation

A character string is a contiguous sequence of bytes in memory, as shown below.

Figure 6: CHARACTER Data Representation

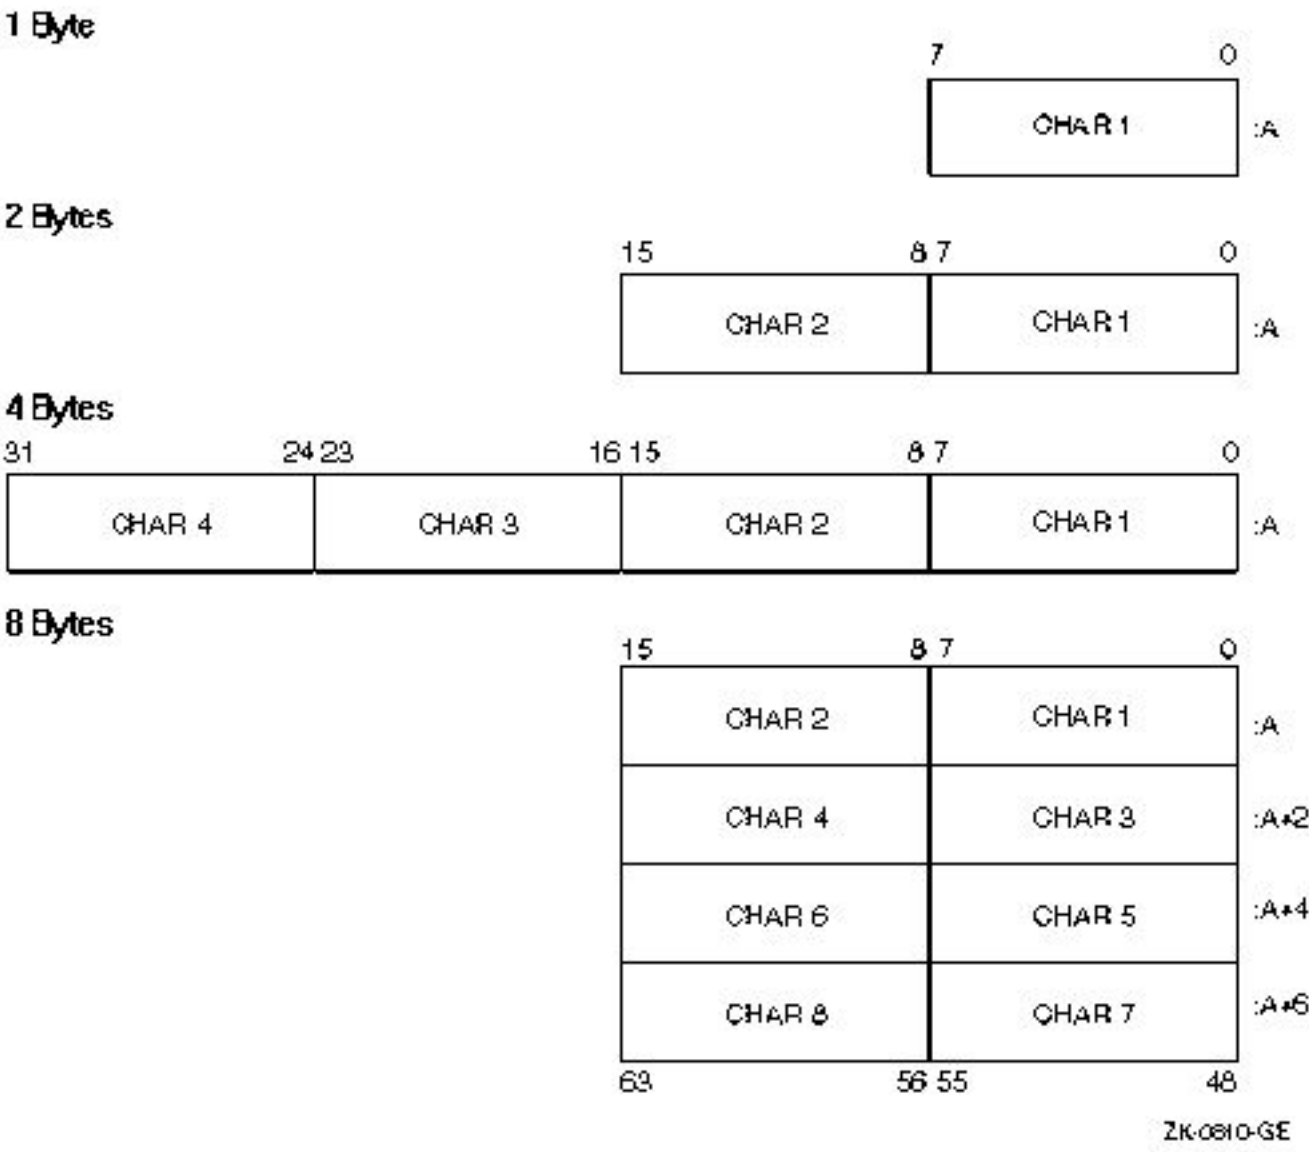


A character string is specified by two attributes: the address A of the first byte of the string, and the length L of the string in bytes. For Windows* OS, the length L of a string is in the range 1 through 2,147,483,647 (2**31-1) . For Linux* OS, the length L of a string is in the range 1 through 2,147,483,647 (2**31-1) for systems based on IA-32 architecture and in the range 1 through 9,223,372,036,854,775,807 (2**63-1) for systems based on Intel® 64 architecture and systems based on IA-64 architecture.

Hollerith Representation

Hollerith constants are stored internally, one character per byte, as shown below.

Figure 7: Hollerith Data Representation



Using Traceback Information

Supported Native and Nonnative Numeric Formats

Data storage in different computers uses a convention of either little endian or big endian storage. The storage convention generally applies to numeric values that span multiple bytes, as follows:

Little endian storage occurs when:

- The least significant bit (LSB) value is in the byte with the lowest address.
- The most significant bit (MSB) value is in the byte with the highest address.
- The address of the numeric value is the byte containing the LSB. Subsequent bytes with higher addresses contain more significant bits.

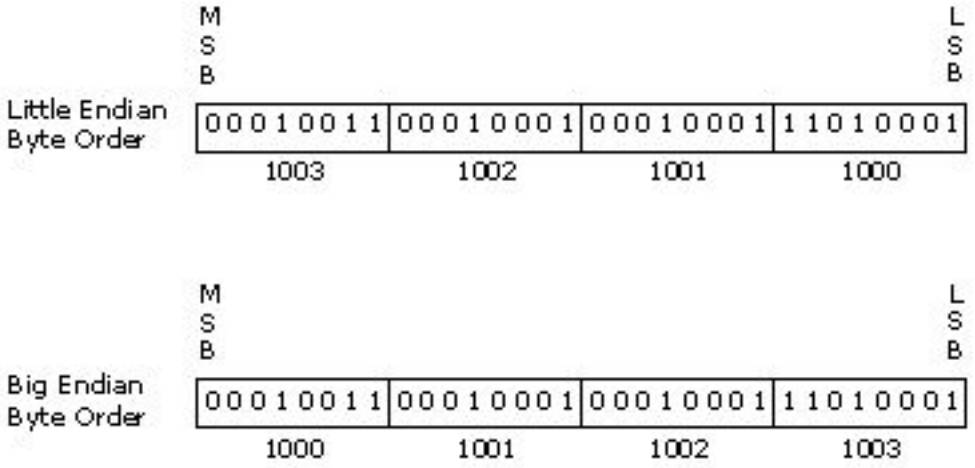
Big endian storage occurs when:

- The least significant bit (LSB) value is in the byte with the highest address.
- The most significant bit (MSB) value is in the byte with the lowest address.
- The address of the numeric value is the byte containing the MSB. Subsequent bytes with higher addresses contain less significant bits.

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte).

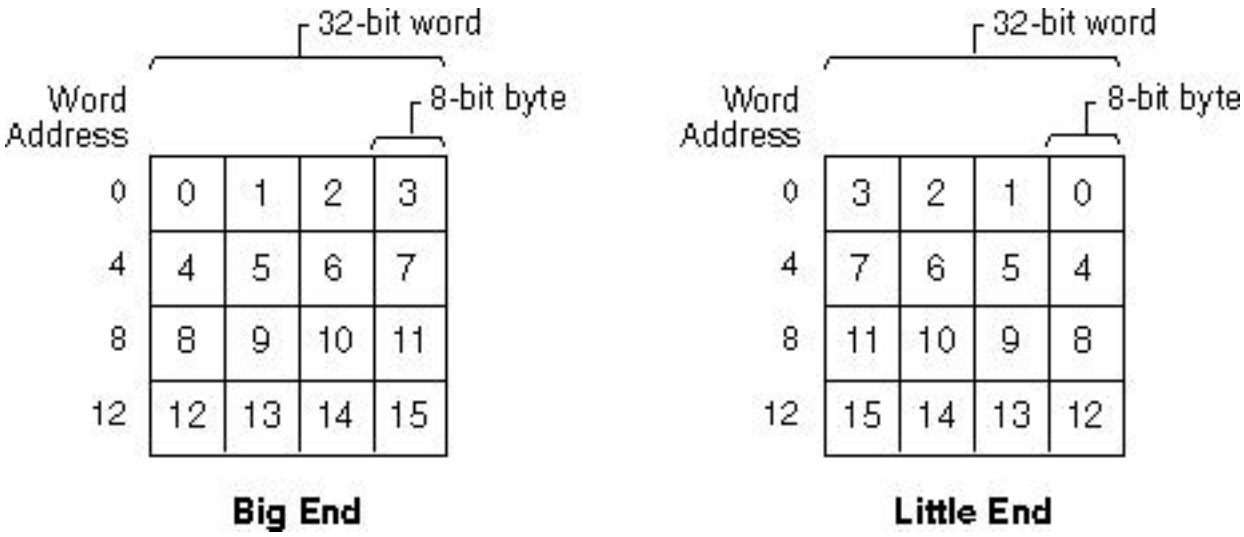
The following figures show the difference between the two byte-ordering schemes:

Figure 8: Little and Big Endian Storage of an INTEGER Value



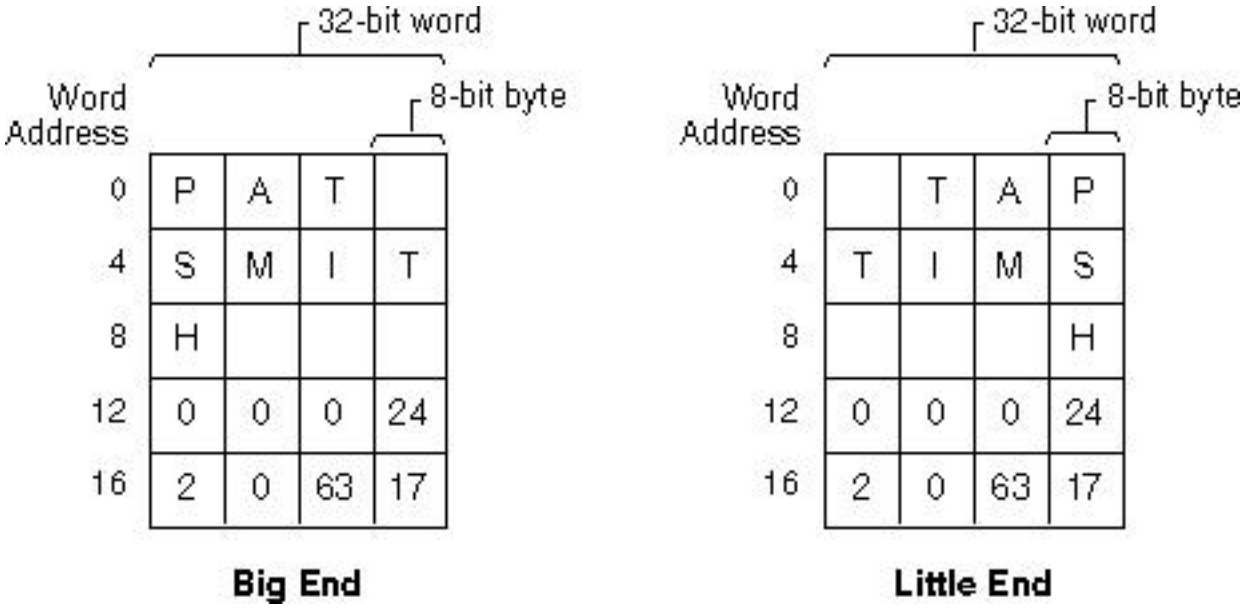
The following figure illustrates the difference between the two conventions for the case of addressing bytes within words.

Figure 9: Byte Order Within Words: (a) Big Endian, (b) Little Endian



Data types stored as subcomponents (bytes stored in words) end up in different locations within corresponding words of the two conventions. The following figure illustrates the difference between the representation of several data types in the two conventions. Letters represent 8-bit character data, while numbers represent the 8-bit partial contribution to 32-bit integer data.

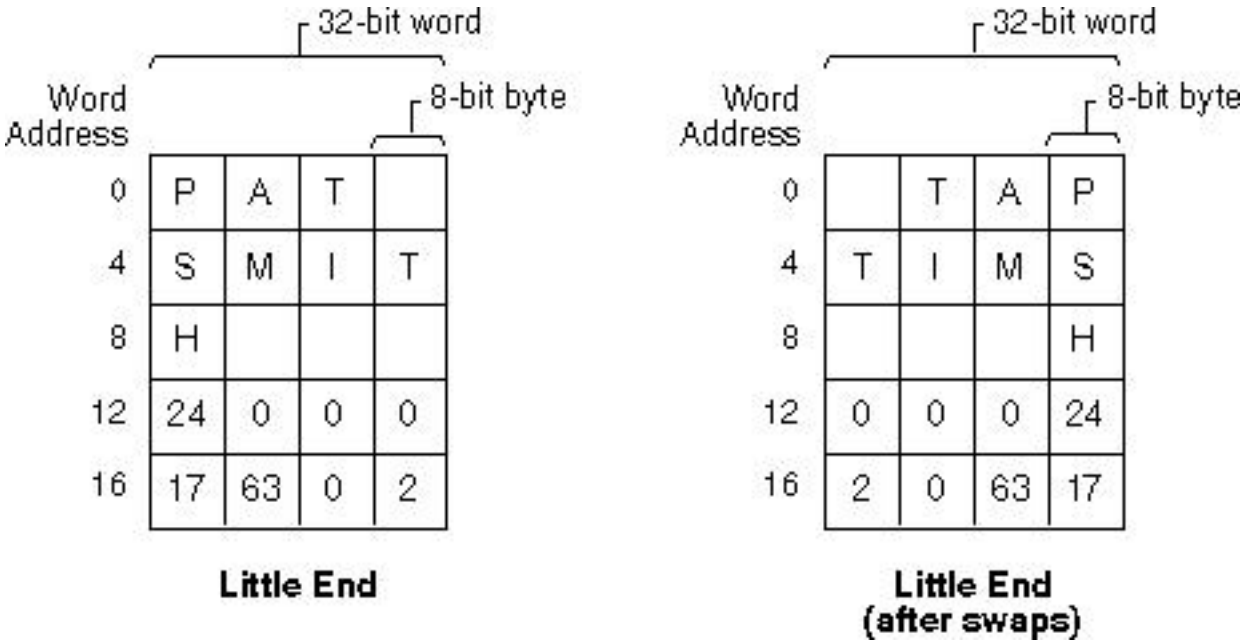
Character and Integer Data in Words: (a) Big Endian, (b) Little Endian



If you serially transfer bytes now from the big endian words to the little endian words (BE byte 0 to LE byte 0, BE byte 1 to LE byte 1, ...), the left half of the figure shows how the data ends up in the little endian words. Note that data of size one byte (characters in this case) is ordered correctly, but that integer data no longer correctly represents the original binary values. The

right half of the figure shows that you need to swap bytes around the middle of the word to reconstitute the correct 32-bit integer values. After swapping bytes, the two preceding figures are identical.

Figure 10: Data Sent from Big to Little: (a) After Transfer, (b) After Byte Swaps



You can generalize the previous example to include floating-point data types and to include multiple-word data types.

Moving unformatted data files between big endian and little endian computers requires that the data be converted.

Intel Fortran provides the capability for programs to read and write unformatted data (originally written using unformatted I/O statements) in several nonnative floating-point formats and in big endian INTEGER or floating-point format. Supported nonnative floating-point formats include Compaq* VAX* little endian floating-point formats supported by Digital* FORTRAN for OpenVMS* VAX Systems, standard IEEE big endian floating-point format found on most Sun Microsystems* systems and IBM RISC* System/6000 systems, IBM floating-point formats (associated with the IBM's System/370 and similar systems), and CRAY* floating-point formats.

Converting unformatted data instead of formatted data is generally faster and is less likely to lose precision of floating-point numbers.

The native memory format includes little endian integers and little endian IEEE floating-point formats, S_floating for REAL(KIND=4) and COMPLEX(KIND=4) declarations, T_floating for REAL(KIND=8) and COMPLEX(KIND=8) declarations, and X_floating for REAL(KIND=16) and COMPLEX(KIND=16) declarations.

The keywords for supported nonnative unformatted file formats and their data types are listed in the following table:

Table 22: Nonnative Numeric Formats, Keywords, and Supported Data Types

Keyword	Description
BIG_ENDIAN	Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian IEEE floating-point formats for REAL and COMPLEX single- and double- and extended-precision numbers. INTEGER(KIND=1) data is the same for little endian and big endian.
CRAY	Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian CRAY proprietary floating-point format for REAL and COMPLEX single- and double-precision numbers.
FDX	Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats: • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4) • VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8) • IEEE style X_float for REAL (KIND=16) and COMPLEX (KIND=16)
FGX	Little endian integer data of the appropriate size (one, two, four, or eight bytes) and and the following little endian proprietary floating-point formats: • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4) • VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8) • IEEE style X_float for REAL (KIND=16) and COMPLEX (KIND=16)
IBM	Big endian integer data of the appropriate INTEGER size (one, two, or four bytes) and big endian IBM proprietary (System\370 and similar) floating-point format for REAL and COMPLEX single- and double-precision numbers.
LITTLE_ENDIAN	Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following native little endian IEEE floating-point formats: • S_float for REAL (KIND=4) and COMPLEX (KIND=4) • T_float for REAL (KIND=8) and COMPLEX (KIND=8)

Keyword	Description
	• IEEE style X_float for REAL (KIND=16) and COMPLEX (KIND=16) For additional information on supported ranges for these data types, see Native IEEE Floating-Point Representations.
NATIVE	No conversion occurs between memory and disk. This is the default for unformatted files.
VAXD	Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats: • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4) • VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8) • VAX H_float for REAL (KIND=16) and COMPLEX (KIND=16)
VAXG	Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats: • VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4) • VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8) • VAX H_float for REAL (KIND=16) and COMPLEX (KIND=16)

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a converted nonnative value is outside the range of the native data type, a run-time message is displayed.

See also:

Environment Variable F_UFMTENDIAN Method

Porting Nonnative Data

Keep this information in mind when porting nonnative data:

- When porting source code along with the unformatted data, vendors might use different units for specifying the record length (RECL specifier) of unformatted files. While formatted files are specified in units of characters (bytes), unformatted files are specified in longword units for Intel Fortran (default) and some other vendors.

To allow you to specify the RECL units (bytes or longwords) for unformatted files without source file modification, use the `-assume byterecl` (Linux OS and Mac OS X) or `/assume:byterecl` (Windows) compiler option. Alternatively, for Windows OS, you can specify Use Bytes as RECL=Unit for Unformatted Files in the Data Options property page.

The Fortran 95 standard (American National Standard Fortran 95, ANSI X3J3/96-007, and International Standards Organization standard ISO/IEC 1539-1:1997) states: "If the file is being connected for unformatted input/output, the length is measured in processor-dependent units."

- Certain vendors apply different `OPEN` statement defaults to determine the record type. The default record type (RECORDTYPE) with Intel Fortran depends on the values for the ACCESS and FORM specifiers for the OPEN statement.
- Certain vendors use a different identifier for the logical data types, such as hex FF instead of 01 to denote "true."
- Source code being ported may be coded specifically for big endian use.

Specifying the Data Format

Methods of Specifying the Data Format

There are a number of methods for specifying a nonnative numeric format for unformatted data:

- Setting an environment variable for a specific unit number before the file is opened. The environment variable is named FORT_CONVERT*n*, where *n* is the unit number. See Environment Variable FORT_CONVERTn Method.
- Setting an environment variable for a specific file name extension before the file is opened. The environment variable is named FORT_CONVERT.*ext* or FORT_CONVERT_*ext*, where *ext* is the file name extension (suffix). See Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method.
- Setting an environment variable for a set of units before the application is executed. The environment variable is named F_UFMTENDIAN. See Environment Variable F_UFMTENDIAN Method.
- Specifying the CONVERT keyword in the OPEN statement for a specific unit number. See OPEN Statement CONVERT Method.
- Compiling the program with an OPTIONS statement that specifies the CONVERT=*keyword* qualifier. This method affects all unit numbers using unformatted data specified by the program. See OPTIONS Statement Method.
- Compiling the program with the appropriate compiler option, which affects all unit numbers that use unformatted data specified by the program. Use the `-convert` *keyword* option for Linux* OS and Mac OS* X or, for Windows* OS, the command-line `/convert:`*keyword* option or the IDE equivalent.

If none of these methods are specified, the native LITTLE_ENDIAN format is assumed (no conversion occurs between disk and memory).

Any keyword listed in Supported Native and Nonnative Numeric Formats can be used with any of these methods, except for the Environment Variable F_UFMTENDIAN Method, which supports only LITTLE_ENDIAN and BIG_ENDIAN.

If you specify more than one method, the order of precedence when you open a file with unformatted data is to:

1. Check for an environment variable (FORT_CONVERT*n*) for the specified unit number (applies to any file opened on a particular unit).
2. Check for an environment variable (FORT_CONVERT.*ext* is checked before FORT_CONVERT_*ext*) for the specified file name extension (applies to all files opened with the specified file name extension).
3. Check for an environment variable (F_UFMTENDIAN) for the specified unit number (or for all units).

NOTE. This environment variable is checked only when the application starts executing.

4. Check the OPEN statement CONVERT specifier.
5. Check whether an OPTIONS statement with a CONVERT=*keyword* qualifier was present when the program was compiled.
6. Check whether the compiler option `-convert` *keyword* (Linux OS and Mac OS X) or `/convert:`*keyword* (Windows OS) was present when the program was compiled.

Environment Variable FORT_CONVERT.ext or FORT_CONVERT_ext Method

You can use this method to specify a non-native numeric format for each specified file name extension (suffix). You specify the numeric format at run time by setting the appropriate environment variable before an implicit or explicit `OPEN` to one or more unformatted files. You can use the format FORT_CONVERT.*ext* or FORT_CONVERT_*ext* (where *ext* is the file extension or suffix). The FORT_CONVERT.*ext* environment variable is checked before FORT_CONVERT_*ext* environment variable (if *ext* is the same).

For example, assume you have a previously compiled program that reads numeric data from one file and writes to another file using unformatted I/O statements. You want the program to read nonnative big endian (IEEE floating-point) format from a file with a .dat file extension and write that data in native little endian format to a file with a extension of .data. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format

(S_float and T_float) when read from file.dat, and then written without conversion in native little endian IEEE format to the file with a suffix of .data, assuming that environment variables FORT_CONVERT.DATA and FORT_CONVERT*n* (for that unit number) are not defined.

Without requiring source code modification or recompilation of a program, the following command sets the appropriate environment variables before running the program:

Linux:

```
setenv FORT_CONVERT.DAT BIG_ENDIAN
```

Windows:

```
set FORT_CONVERT.DAT=BIG_ENDIAN
```

The FORT_CONVERT*n* method takes precedence over this method. When the appropriate environment variable is set when you open the file, the FORT_CONVERT.*ext* or FORT_CONVERT_*ext* environment variable is used if a FORT_CONVERT*n* environment variable is not set for the unit number.

The FORT_CONVERT*n* and the FORT_CONVERT.*ext* or FORT_CONVERT_*ext* environment variable methods take precedence over the other methods. For instance, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

You can set the appropriate environment variable using the format FORT_CONVERT.*ext* or FORT_CONVERT_*ext*. If you also use Intel Fortran on Linux* systems, consider using the FORT_CONVERT_*ext* form, because a dot (.) cannot be used for environment variable names on certain Linux command shells. If you do define both FORT_CONVERT.*ext* and FORT_CONVERT_*ext* for the same extension (*ext*), the file defined by FORT_CONVERT.*ext* is used.

On Windows systems, the file name extension (suffix) is not case-sensitive. The extension must be part of the file name (not the directory path).

Environment Variable FORT_CONVERT*n* Method

You can use this method to specify a non-native numeric format for each specified unit number. You specify the numeric format at run time by setting the appropriate environment variable before an implicit or explicit `OPEN` to that unit number.

When the appropriate environment variable is set when you open the file, the environment variable is always used because this method takes precedence over the other methods. For instance, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

For example, assume you have a previously compiled program that reads numeric data from unit 28 and writes it to unit 29 using unformatted I/O statements. You want the program to read nonnative big endian (IEEE floating-point) format from unit 28 and write that data in

native little endian format to unit 29. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format when read from unit 28, and then written without conversion in native little endian IEEE format to unit 29.

Without requiring source code modification or recompilation of this program, the following command sequence sets the appropriate environment variables before running a program.

Linux:

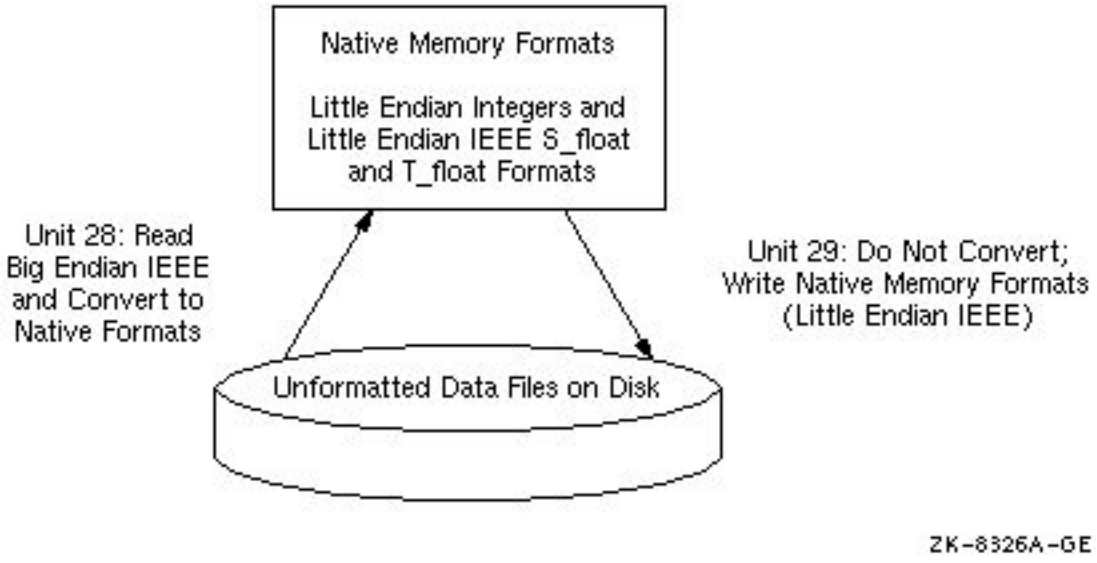
```
setenv FORT_CONVERT28 BIG_ENDIAN
setenv FORT_CONVERT29 NATIVE
```

Windows:

```
set FORT_CONVERT28=BIG_ENDIAN
set FORT_CONVERT29=NATIVE
```

The following figure shows the data formats used on disk and in memory when the program is run after the environment variables are set.

Figure 11: Sample Unformatted File Conversion



This method takes precedence over other methods.

Environment Variable F_UFMTENDIAN Method

This little-endian-big-endian conversion feature is intended for Fortran unformatted input/output operations. It enables the development and processing of files with little-endian and big-endian data organization.

The F_UFMTENDIAN environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units or for all units continues for the rest of the execution.

Specify the numbers of the units to be used for conversion purposes by setting `F_UFMTENDIAN`. Then, the `READ`/`WRITE` statements that use these unit numbers will perform relevant conversions. Other `READ`/`WRITE` statements will work in the usual way.

General Syntax for F_UFMTENDIAN

In the general case, the variable consists of two parts divided by a semicolon. No spaces are allowed inside the `F_UFMTENDIAN` value:

```
F_UFMTENDIAN=MODE | [MODE;] EXCEPTION
```

where:

```
MODE = big | little
EXCEPTION = big:ULIST | little:ULIST | ULIST
ULIST = U | ULIST,U
U = decimal | decimal -decimal
```

- `MODE` defines current format of data, represented in the files; it can be omitted.

  The keyword `little` means that the data has little endian format and will not be converted.This is the default.

  The keyword `big` means that the data has big endian format and will be converted.

- `EXCEPTION` is intended to define the list of exclusions for `MODE`.`EXCEPTION` keyword (`little` or `big`) defines data format in the files that are connected to the units from the `EXCEPTION` list. This value overrides `MODE` value for the units listed.

  The `EXCEPTION` keyword and the colon can be omitted. The default when the keyword is omitted is `big`.

- Each list member `U` is a simple unit number or a number of units. The number of list members is limited to 64.
- `decimal` is a non-negative decimal number less than 232.

Converted data should have basic data types, or arrays of basic data types. Derived data types are disabled.

Error messages may be issued during the little-endian-to-big-endian conversion. They are all fatal.

On Linux* systems, the command line for the variable setting in the shell is:

```
Sh: export F_UFMTENDIAN=MODE;EXCEPTION
```

NOTE. The environment variable value should be enclosed in quotes if the semicolon is present.

The environment variable can also have the following syntax:

```
F_UFMTENDIAN=u[,u] . . .
```

Examples

1. `F_UFMTENDIAN=big`

   All input/output operations perform conversion from `big-endian` to `little-endian` on `READ` and from little-endian to `big-endian` on `WRITE`.

2. `F_UFMTENDIAN="little;big:10,20"`

   or `F_UFMTENDIAN=big:10,20`

   or `F_UFMTENDIAN=10,20`

   The input/output operations perform big-endian to little endian conversion only on unit numbers 10 and 20.

3. `F_UFMTENDIAN="big;little:8"`

   No conversion operation occurs on unit number 8. On all other units, the input/output operations perform big-endian to little-endian conversion.

4. `F_UFMTENDIAN=10-20`

   The input/output operations perform big-endian to little-endian conversion on units 10, 11, 12 , ... 19, 20.

5. Assume you set `F_UFMTENDIAN=10,100` and run the following program.

```
integer*4   cc4
integer*8   cc8
integer*4   c4
integer*8   c8
c4 = 456
c8 = 789
```

```
C prepare a little endian representation of data

open(11,file='lit.tmp',form='unformatted')
write(11) c8
write(11) c4
close(11)

C prepare a big endian representation of data

open(10,file='big.tmp',form='unformatted')
write(10) c8
write(10) c4
close(10)

C read big endian data and operate with them on
C  little endian machine.

open(100,file='big.tmp',form='unformatted')
read(100) cc8
read(100) cc4

C Any operation with data, which have been read

C . . .
close(100)
stop
end
```

Now compare `lit.tmp` and `big.tmp` files with the help of the `od` utility:

```
> od -t x4 lit.tmp
0000000 00000008 00000315 00000000 00000008
0000020 00000004 000001c8 00000004
0000034
> od -t x4 big.tmp
0000000 08000000 00000000 15030000 08000000
0000020 04000000 c8010000 04000000
0000034
```

You can see that the byte order is different in these files.

OPEN Statement CONVERT Method

You can use this method to specify a non-native numeric format for each specified unit number. This method requires an explicit file OPEN statement to specify the numeric format of the file for that unit number.

This method takes precedence over the OPTIONS statement and the compiler option `-convert keyword` (Linux OS and Mac OS X) or `/convert:keyword` (Windows OS) method, but has a lower precedence than the environment variable methods.

For example, the following source code shows how the OPEN statement would be coded to read unformatted VAXD numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20 (the absence of the CONVERT keyword or environment variables `FORT_CONVERT20`, `FORT_CONVERT.dat`, or `FORT_CONVERT_dat` indicates native little endian data for unit 20):

```
OPEN (CONVERT='VAXD', FILE='graph3.dat', FORM='UNFORMATTED', UNIT=15)
  .
  .
  .
OPEN (FILE='graph3_t.dat', FORM='UNFORMATTED', UNIT=20)
```

A hard-coded OPEN statement CONVERT keyword value cannot be changed after compile time. However, to allow selection of a particular format at run time, equate the CONVERT keyword to a variable and provide the user with a menu that allows selection of the appropriate format (menu choice sets the variable) before the `OPEN` occurs.

You can also select a particular format at run time for a unit number by using one of the environment variable methods (FORT_CONVERTn, FORT_CONVERT.ext or FORT_CONVERT_ext, or F_UFMTENDIAN), which take precedence over the `OPEN` statement CONVERT *`keyword`* method.

OPTIONS Statement Method

You can only specify one numeric file format for all unformatted file unit numbers using this method unless you also use one of the environment variable methods or `OPEN` statement CONVERT keyword method.

You specify the numeric format at compile time and must compile all routines under the same OPTIONS statement /CONVERT=*`keyword`* qualifier. You could use one source program and compile it using different ifort commands to create multiple executable programs that each read a certain format.

The environment variable methods and the `OPEN` statement CONVERT *`keyword`* method take precedence over this method. For instance, you might use the FORT_CONVERT*n* environment variable or `OPEN` CONVERT *`keyword`* method to specify each unit number that will use a format other than that specified using the `ifort` *`option`* method.

This method takes precedence over the `ifort -convert` keyword (Linux OS and Mac OS X) or `/convert:`*`keyword`* (Windows OS) compiler option method.

You can use OPTIONS statements to specify the appropriate floating-point formats (in memory and in unformatted files) instead of using the corresponding `ifort` command qualifiers. For example, to use VAX F_floating, G_floating, and X_floating as the unformatted file format, specify the following OPTIONS statement:

```
OPTIONS /CONVERT=VAXG
```

Because this method affects all unit numbers, you cannot read data in one format and write it in another format, unless you use it in combination with one of the environment variable methods or the OPEN statement CONVERT keyword method to specify a different format for a particular unit number.

For more information, see the OPTIONS statement.

Compiler Option -convert or /convert Method

You can only specify one numeric format for all unformatted file unit numbers using the compiler option `-convert` (Linux OS and Mac OS X) or `/convert` (Windows OS) method unless you also use one (or more) of the previous methods.

You specify the numeric format at compile time and must compile all routines under the same `-convert`*keyword* (Linux OS and Mac OS X) or `/convert:`*keyword* (Windows OS) compiler option. You can use the same source program and compile it using different ifort commands (or the equivalent in the IDE) to create multiple executable programs that each read a certain format.

If you specify other methods, they take precedence over this method. For instance, you might use the environment variable or OPEN statement CONVERT keyword method to specify each unit number that will use a format different than that specified using the `-convert` *keyword* (Linux OS and Mac OS X) or `/convert:`*keyword* (Windows OS) compiler option method for all other unit numbers.

For example, the following command compiles program `file.for` to use VAX D_floating (and F_floating) floating-point data for all unit numbers (unless superseded by one of the other methods). Data is converted between the file format and the little endian memory format (little endian integers, S_floating, T_floating, and X_floating little endian IEEE* floating-point format). The created file, `vconvert.exe`, can then be run:

Linux OS and Mac OS X:

```
ifort file.for -o vconvert.exe -convert vaxd
```

Windows OS:

```
ifort file.for /convert:vaxd /link /out:vconvert.exe
```

Because this method affects all unformatted file unit numbers, you cannot read data in one format and write it in another file format using the `-convert keyword` (Linux OS and Mac OS X) or `/convert:`*keyword* (Windows OS) compiler option method alone. You can if you use it in combination with the environment variable methods or the OPEN statement CONVERT keyword method to specify a different format for a particular unit number.

For more information, see the following topic:

- convert compiler option

Fortran I/O

Devices and Files Overview

In Fortran's I/O system, data is stored and transferred among files. All I/O data sources and destinations are considered files.

Devices such as the screen, keyboard and printer are external files, as are data files stored on a device such as a disk.

Variables in memory can also act as a file on a disk, and are typically used to convert ASCII representations of numbers to binary form. When variables are used in this way, they are called internal files.

Topics covered in this section include the following:

- Logical Devices
- Types and Forms of I/O Statements
- File Organization, File Access and File Structure
- Internal Files and Scratch Files
- File Records, including Record Types, Length, Access, and Transfer
- Using I/O Statements such as OPEN, INQUIRE, and CLOSE

For information on techniques you can use to improve I/O performance, see Improving I/O Performance.

Logical Devices

Every file, internal or external, is associated with a logical device. You identify the logical device associated with a file by a unit specifier (UNIT=). The unit specifier for an internal file is the name of the character variable associated with it. The unit specifier for an external file is either a number you assign with the `OPEN` statement, a number preconnected as a unit specifier to a device, or an asterisk (*).

The OPEN statement connects a unit number with an external file and allows you to explicitly specify file attributes and run-time options using OPEN statement specifiers. External unit specifiers that are preconnected to certain devices do not have to be opened. External units that you connect are disconnected when program execution terminates or when the unit is closed by a `CLOSE` statement.

A unit must not be connected to more than one file at a time, and a file must not be connected to more than one unit at a time. You can OPEN an already opened file but only to change some of the I/O options for the connection, not to connect an already opened file or unit to a different unit or file.

You must use a unit specifier for all I/O statements, except in the following six cases:

- ACCEPT, which always reads from standard input, unless the FOR_ACCEPT environment variable is defined.
- INQUIRE by file, which specifies the filename, rather than the unit with which the file is associated.
- PRINT, which always writes to standard output, unless the FOR_PRINT environment variable is defined.
- READ statements that contain only an I/O list and format specifier, which read from standard input (UNIT=5), unless the FOR_READ environment variable is defined.
- WRITE statements that contain only an I/O list and format specifier, which write to standard output, unless the FOR_PRINT environment variable is defined.
- TYPE, which always writes to standard output, unless the FOR_TYPE environment variable is defined.

External Files

A unit specifier associated with an external file must be either an integer expression or an asterisk (*). The integer expression must be in the range 0 (zero) to a maximum value of 2,147,483,640. (The predefined parameters FOR_K_PRINT_UNITNO, FOR_K_TYPE_UNITNO, FOR_K_ACCEPT_UNITNO, and FOR_K_READ_UNITNO may not be in that range. For more information, see the Language Reference.)

The following example connects the external file UNDAMP.DAT to unit 10 and writes to it:

```
OPEN (UNIT = 10, FILE = 'UNDAMP.DAT')
WRITE (10, '(A18,\)') ' Undamped Motion:'
```

The asterisk (*) unit specifier specifies the keyboard when reading and the screen when writing. The following example uses the asterisk specifier to write to the screen:

```
WRITE (*, '(1X, A30,\)') ' Write this to the screen.'
```

Intel Fortran has four units preconnected to external files (devices), as shown in the following table.

External Unit Specifier	Environment Variable	Description

Asterisk (*)	None	Always represents the keyboard and screen (unless the appropriate environment variable is defined, such as FOR_READ).
0	FORT0	Initially represents the screen (unless FORT0 is explicitly defined)
5	FORT5	Initially represents the keyboard (unless FORT5 is explicitly defined)
6	FORT6	Initially represents the screen (unless FORT6 is explicitly defined)

The asterisk (*) specifier is the only unit specifier that cannot be reconnected to another file, and attempting to close this unit causes a compile-time error. Units 0, 5, and 6, however, can be connected to any file with the `OPEN` statement. If you close unit 0, 5, or 6, it is automatically reconnected to its preconnected device the next time an I/O statement attempts to use that unit.

Intel® Fortran does not support buffering to `stdout` or `stdin`. All I/O to units * and 6 use line buffering. Therefore, C and Fortran output to stdout should work well as long as the C code is not performing buffering. In the case of buffering, the C code will have to flush the buffers with each write. For more information on `stdout` and `stdin`, see Assigning Files to Logical Units.

You can change these preconnected files by doing one of the following:

- Using an OPEN statement to open unit 5, 6, or 0. When you explicitly OPEN a file for unit 5, 6, or 0, the OPEN statement keywords specify the file-related information to be used instead of the preconnected standard I/O file.
- Setting the appropriate environment variable (`FORT`*`n`*) to redirect I/O to an external file.

To redirect input or output from the standard preconnected files at run time, you can set the appropriate environment variable or use the appropriate shell redirection character in a pipe (such as > or <).

When you omit the file name in the OPEN statement or use an implicit OPEN, you can define the environment variable FORT*n* to specify the file name for a particular unit number *n*. An exception to this is when the compiler option `-fpscomp filesfromcmd` (Linux* OS and Mac OS* X) or `/fpscomp:filesfromcmd` (Windows) is specified.

For example, if you want unit 6 to write to a file instead of standard output, set the environment variable FORT6 to the path and filename to be used before you run the program. If the appropriate environment variable is not defined, a default filename is used, in the form fort.*n* where *n* is the logical unit number.

The following example writes to the preconnected unit 6 (the screen), then reconnects unit 6 to an external file and writes to it, and finally reconnects unit 6 to the screen and writes to it:

```
     REAL a, b
!  Write to the screen (preconnected unit 6).
    WRITE(6, '('' This is unit 6'')')
!  Use the OPEN statement to connect unit 6
!  to an external file named 'COSINES'.
    OPEN (UNIT = 6, FILE = 'COSINES', STATUS = 'NEW')
    DO a = 0.1, 6.3, 0.1
         b = COS (a)
!  Write to the file 'COSINES'.
          WRITE (6, 100) a, b
100        FORMAT (F3.1, F5.2)
    END DO
!  Close it.
    CLOSE (6)
!  Reconnect unit 6 to the screen, by writing to it.
    WRITE(6,' ('' Cosines completed'')')
    END
```

Internal Files

The unit specifier associated with an internal file is a character string or character array. There are two types of internal files:

- An internal file that is a character variable, character array element, or noncharacter array element has exactly one record, which is the same length as the variable, array element, or noncharacter array element.
- An internal file that is a character array, a character derived type, or a noncharacter array is a sequence of elements, each of which is a record. The order of records is the same as the order of array elements or type elements, and the record length is the length of one array element or the length of the derived-type element.

Follow these rules when using internal files:

- Use only formatted I/O, including I/O formatted with a format specification and list-directed I/O. (List-directed I/O is treated as sequential formatted I/O.) Namelist formatting is not allowed.

- If the character variable is an allocatable array or array part of an allocatable array, the array must be allocated before use as an internal file. If the character variable is a pointer, it must be associated with a target.
- Use only READ and WRITE statements. You cannot use file connection (`OPEN`, `CLOSE`), file positioning (`REWIND`, `BACKSPACE`), or file inquiry (`INQUIRE`) statements with internal files.

You can read and write internal files with `FORMAT` I/O statements or list-directed I/O statements exactly as you can external files. Before an I/O statement is executed, internal files are positioned at the beginning of the variable, before the first record.

With internal files, you can use the formatting capabilities of the I/O system to convert values between external character representations and Fortran internal memory representations. That is, reading from an internal file converts the ASCII representations into numeric, logical, or character representations, and writing to an internal file converts these representations into their ASCII representations.

This feature makes it possible to read a string of characters without knowing its exact format, examine the string, and interpret its contents. It also makes it possible, as in dialog boxes, for the user to enter a string and for your application to interpret it as a number.

If less than an entire record is written to an internal file, the rest of the record is filled with blanks.

In the following example, `str` and `fname` specify internal files:

```
    CHARACTER(10) str
   INTEGER n1, n2, n3
   CHARACTER(14) fname
   INTEGER   i
   str = " 1   2   3"
! List-directed READ sets n1 = 1, n2 = 2, n3 = 3.
   READ(str, *) n1, n2, n3
   i = 4
! Formatted WRITE sets fname = 'FM004.DAT'.
   WRITE (fname, 200) i
200 FORMAT ('FM', I3.3, '.DAT')
```

Types of I/O Statements

The table below lists the Intel Fortran I/O statements:

Category and statement name	Description
File connection	

Category and statement name	Description
OPEN	Connects a unit number with an external file and specifies file connection characteristics.
CLOSE	Disconnects a unit number from an external file.
File inquiry	
DEFINE FILE	Specifies file characteristics for a direct access relative file and connects the unit number to the file, similar to an OPEN statement. Provided for compatibility with compilers older than FORTRAN-77.
INQUIRE	Returns information about a named file, a connection to a unit, or the length of an output item list.
Record position	
BACKSPACE	Moves the record position to the beginning of the previous record (sequential access only).
DELETE	Marks the record at the current record position in a relative file as deleted (direct access only).
ENDFILE	Writes an end-of-file marker after the current record (sequential access only).
FIND	Changes the record position in a direct access file. Provided for compatibility with compilers older than FORTRAN-77.
REWIND	Sets the record position to the beginning of the file (sequential access only).
Record input	
READ	Transfers data from an external file record or an internal file to internal storage.
ACCEPT	Reads input from stdin. Unlike READ, ACCEPT only provides formatted sequential input and does not specify a unit number.
Record output	

Category and statement name	Description
WRITE	Transfers data from internal storage to an external file record or to an internal file.
REWRITE	Transfers data from internal storage to an external file record at the current record position (direct access relative files only).
TYPE	Writes record output to stdout.
PRINT	Transfers data from internal storage to stdout. Unlike WRITE, PRINT only provides formatted sequential output and does not specify a unit number.
FLUSH	Flushes the contents of an external unit's buffer to its associated file.

In addition to the READ, WRITE, REWRITE, TYPE, and PRINT statements, other I/O record-related statements are limited to a specific file organization. For instance:

- The DELETE statement only applies to relative files. (Detecting deleted records is only available if the `-vms` option was specified when the program was compiled.)
- The BACKSPACE statement only applies to sequential files open for sequential access.
- The REWIND statement only applies to sequential files open for sequential access and to direct access files.
- The ENDFILE statement only applies to certain types of sequential files open for sequential access and to direct access files.

The file-related statements (OPEN, INQUIRE, and CLOSE) apply to any relative or sequential file.

Forms of I/O Statements

Each type of record I/O statement can be coded in a variety of forms. The form you select depends on the nature of your data and how you want it treated. When opening a file, specify the form using the FORM specifier.

The following are the forms of I/O statements:

- *Formatted I/O statements* contain explicit format specifiers that are used to control the translation of data from internal (binary) form within a program to external (readable character) form in the records, or vice versa.

- *List-directed* and *namelist I/O statements* are similar to formatted statements in function. However, they use different mechanisms to control the translation of data: formatted I/O statements use explicit format specifiers, and list-directed and namelist I/O statements use data types.
- *Unformatted I/O statements* do not contain format specifiers and therefore do not translate the data being transferred (important when writing data that will be read later).

Formatted, list-directed, and namelist I/O forms require translation of data from internal (binary) form within a program to external (readable character) form in the records. Consider using unformatted I/O for the following reasons:

- Unformatted data avoids the translation process, so I/O tends to be faster.
- Unformatted data avoids the loss of precision in floating-point numbers when the output data will subsequently be used as input data.
- Unformatted data conserves file storage space (stored in binary form).

To write data to a file using formatted, list-directed, or namelist I/O statements, specify FORM= 'FORMATTED' when opening the file. To write data to a file using unformatted I/O statements, specify FORM= 'UNFORMATTED' when opening the file.

Data written using formatted, list-directed, or namelist I/O statements is referred to as formatted data; data written using unformatted I/O statements is referred to as unformatted data.

When reading data from a file, you should use the same I/O statement form that was used to write the data to the file. For instance, if data was written to a file with a formatted I/O statement, you should read data from that file with a formatted I/O statement.

Although I/O statement form is usually the same for reading and writing data in a file, a program can read a file containing unformatted data (using unformatted input) and write it to a separate file containing formatted data (using formatted output). Similarly, a program can read a file containing formatted data and write it to a different file containing unformatted data.

You can access records in any sequential or relative file using sequential access. For relative files and certain (fixed-length) sequential files, you can also access records using direct access.

The table below shows the main record I/O statements, by category, that can be used in Intel Fortran programs.

File Type, Access, and I/O Form	Available Statements
External file, sequential access	
Formatted	READ, WRITE, PRINT, ACCEPT, TYPE, REWRITE
List-directed	READ, WRITE, PRINT, ACCEPT, TYPE

File Type, Access, and I/O Form	Available Statements
Namelist	READ, WRITE, PRINT, ACCEPT, TYPE
Unformatted	READ, WRITE, REWRITE
External file, direct access	
Formatted	READ, WRITE, REWRITE
Unformatted	READ, WRITE, REWRITE
External file, stream access	
Formatted	READ, WRITE
List-directed	READ, WRITE
Namelist	READ, WRITE
Unformatted	READ, WRITE
Internal file	
Formatted	READ, WRITE
List-directed	READ, WRITE
Unformatted	None

NOTE. You can use the REWRITE statement only for relative files, using direct access.

Assigning Files to Logical Units

Most I/O operations involve a disk file, keyboard, or screen display. Other devices can also be used:

- Sockets can be read from or written to if a USEROPEN routine (usually written in C) is used to open the socket.
- Pipes opened for read and write access block (wait until data is available) if you issue a READ to an empty pipe.

- Pipes opened for read-only access return EOF if you issue a READ to an empty pipe.

You can access the terminal screen or keyboard by using preconnected files listed in Logical Devices.

You can choose to assign files to logical units by using one of the following methods:

- Using default values, such as a preconnected unit
- Supplying a file name (and possibly a directory) in an OPEN statement
- Using environment variables

Using Default Values

In the following example, the PRINT statement is associated with a preconnected unit (stdout) by default.

```
PRINT *,100
```

The READ statement associates the logical unit 7 with the file `fort.7` (because the FILE specifier was omitted) by default:

```
OPEN (UNIT=7,STATUS='NEW')
READ (7,100)
```

Supplying a File Name in an OPEN Statement

The FILE specifier in an OPEN statement typically specifies only a file name (such as `filnam`) or contains both a directory and file name (such as `/usr/proj/filnam`).

For example:

```
OPEN (UNIT=7, FILE='FILNAM.DAT', STATUS='OLD')
```

The DEFAULTFILE specifier in an OPEN statement typically specifies a pathname that contains only a directory (such as `/usr/proj/`) or both a directory and file name (such as `/usr/proj/testdata`).

Implied OPEN

Performing an implied OPEN means that the FILE and DEFAULTFILE specifier values are not specified and an environment variable is used, if present. Thus, if you used an implied OPEN, or if the FILE specifier in an OPEN statement did not specify a file name, you can use an environment variable to specify a file name or a pathname that contains both a directory and file name.

Using Environment Variables

You can use shell commands to set the appropriate environment variable to a value that indicates a directory (if needed) and a file name to associate a unit with an external file.

Intel Fortran recognizes environment variables for each logical I/O unit number in the form of FORT`n`, where `n` is the logical I/O unit number. If a file name is not specified in the OPEN statement and the corresponding FORT`n` environment variable is not set for that unit number, Intel Fortran generates a file name in the form fort.`n`, where `n` is the logical unit number.

Implied Intel Fortran Logical Unit Numbers

The ACCEPT, PRINT, and TYPE statements, and the use of an asterisk (*) in place of a unit number in READ and WRITE statements, do not include an explicit logical unit number.

Each of these Fortran statements uses an implicit internal logical unit number and environment variable. Each environment variable is in turn associated by default with one of the Fortran file names that are associated with standard I/O files. The table below shows these relationships:

Intel Fortran statement	Environment variable	Standard I/O file name
READ (*,f) iolist	FOR_READ	stdin
READ f,iolist	FOR_READ	stdin
ACCEPT f,iolist	FOR_ACCEPT	stdin
WRITE (*,f) iolist	FOR_PRINT	stdout
PRINT f,iolist	FOR_PRINT	stdout
TYPE f,iolist	FOR_TYPE	stdout
WRITE(0,f) iolist	FORT0	stderr
READ(5,f) iolist	FORT5	stdin
WRITE(6,f) iolist	FORT6	stdout

You can change the file associated with these Intel Fortran environment variables, as you would any other environment variable, by means of the environment variable assignment command. For example:

```
setenv FOR_READ /usr/users/smith/test.dat
```

After executing the preceding command, the environment variable for the READ statement using an asterisk refers to file `test.dat` in the specified directory.

NOTE. The association between the logical unit number and the physical file can occur at run-time. Instead of changing the logical unit numbers specified in the source program, you can change this association at run time to match the needs of the program and the available resources. For example, before running the program, a script file can set the appropriate environment variable or allow the terminal user to type a directory path, file name, or both.

File Organization

File organization refers to the way records are physically arranged on a storage device. This topic describes the two main types of file organization.

Related topics describe the following:

- *Record type* refers to whether records in a file are all the same length, are of varying length, or use other conventions to define where one record ends and another begins. For more information on record types, see Record Types.
- *Record access* refers to the method used to read records from or write records to a file, regardless of its organization. The way a file is organized does not necessarily imply the way in which the records within that file will be accessed. For more information on record access, see File Access and File Structure and Record Access.

Types of File Organization

Fortran supports two types of file organizations:

- Sequential
- Relative

The organization of a file is specified by means of the ORGANIZATION keyword in the `OPEN` statement.

The default file organization is always ORGANIZATION= 'SEQUENTIAL' for an OPEN statement.

You can store sequential files on magnetic tape or disk devices, and can use other peripheral devices, such as terminals, pipes, and line printers as sequential files.

You must store relative files on a disk device.

Sequential File Organization

A sequentially organized file consists of records arranged in the sequence in which they are written to the file (the first record written is the first record in the file, the second record written is the second record in the file, and so on). As a result, records can be added only at the end of the file. Attempting to add records at some place other than the end of the file will result in the file begin truncated at the end of the record just written.

Sequential files are usually read sequentially, starting with the first record in the file. Sequential files with a fixed-length record type that are stored on disk can also be accessed by relative record number (direct access).

Relative File Organization

Within a relative file are numbered positions, called *cells*. These cells are of fixed equal length and are consecutively numbered from 1 to *n*, where 1 is the first cell, and *n* is the last available cell in the file. Each cell either contains a single record or is empty. Records in a relative file are accessed according to cell number. A cell number is a record's relative record number; its location relative to the beginning of the file. By specifying relative record numbers, you can directly retrieve, add, or delete records regardless of their locations. (Detecting deleted records is only available if you specified the `-vms` (Linux OS and Mac OS X) or `/vms` (Windows OS) option when the program was compiled.)

When creating a relative file, use the RECL value to determine the size of the fixed-length cells. Within the cells, you can store records of varying length, as long as their size does not exceed the cell size.

Internal Files and Scratch Files

Intel Fortran supports two other types of files:

- Internal files
- Scratch files

Internal Files

When you use sequential access, you can use an internal file to reference character data in a buffer. The transfer occurs between internal storage and internal storage (unlike external files), such as between user variables and a character array.

An internal file consists of any of the following:

- Character variable
- Character-array element
- Character array
- Character substring
- Character array section without a vector subscript

Instead of specifying a unit number for the READ or WRITE statement, use an internal file specifier in the form of a character scalar memory reference or a character-array name reference.

An internal file is a designated internal storage space (variable buffer) of characters that is treated as a sequential file of fixed-length records. To perform internal I/O, use formatted and list-directed sequential READ and WRITE statements. You cannot use file-related statements such as OPEN and INQUIRE on an internal file (no unit number is used).

If an internal file is made up of a single character variable, array element, or substring, that file comprises a single record whose length is the same as the length of the character variable, array element, or substring it contains. If an internal file is made up of a character array, that file comprises a sequence of records, with each record consisting of a single array element. The sequence of records in an internal file is determined by the order of subscript progression.

A record in an internal file can be read only if the character variable, array element, or substring comprising the record has been defined (a value has been assigned to the record).

Prior to each READ and WRITE statement, an internal file is always positioned at the beginning of the first record.

Scratch Files

Scratch files are created by specifying STATUS= 'SCRATCH' in an OPEN statement. By default, these temporary files are created in (and later deleted from) the directory specified in the OPEN statement DEFAULTFILE (if specified).

File Access and File Structure

Fortran supports three methods of file access:

- Sequential
- Direct
- Stream

Fortran supports three kinds of file structure:

- Formatted
- Unformatted
- Binary

Sequential-access and direct-access files can have any of the three file structures. Stream-access files can have a file structure of formatted or unformatted.

Choosing a File Access and File Structure

Each kind of file has advantages and the best choice depends on the application you are developing:

- Formatted Files

  You create a formatted file by opening it with the FORM='FORMATTED' option, or by omitting the FORM parameter when creating a sequential file. The records of a formatted file are stored as ASCII characters; numbers that would otherwise be stored in binary form are converted to ASCII format. Each record ends with the ASCII carriage return (CR) and/or line feed (LF) characters.

  If you need to view a data file's contents, use a formatted file. You can load a formatted file into a text editor and read its contents directly, that is, the numbers would look like numbers and the strings like character strings, whereas an unformatted or binary file looks like a set of hexadecimal characters.

- Unformatted Files

  You create an unformatted file by opening it with the FORM='UNFORMATTED' option, or by omitting the FORM parameter when creating a direct-access file. An unformatted file is a series of records composed of physical blocks. Each record contains a sequence of values stored in a representation that is close to that used in program memory. Little conversion is required during input/output.

  The lack of formatting makes these files quicker to access and more compact than files that store the same information in a formatted form. However, if the files contain numbers, you will not be able to read them with a text editor.

- Binary Files

  You create a binary file by specifying FORM='BINARY'. Binary files are similar to unformatted files, except binary files have no internal record format associated with them.

- Sequential-Access Files

Data in sequential files must be accessed in order, one record after the other (unless you change your position in the file with the REWIND or BACKSPACE statements). Some methods of I/O are possible only with sequential files, including nonadvancing I/O, list-directed I/O, and namelist I/O. Internal files also must be sequential files. You must use sequential access for files associated with sequential devices.

A sequential device is a physical storage device that does not allow explicit motion (other than reading or writing). The keyboard, screen, and printer are all sequential devices.

- Direct-Access Files

  Data in direct-access files can be read or written to in any order. Records are numbered sequentially, starting with record number 1. All records have the length specified by the RECL option in the OPEN statement. Data in direct files is accessed by specifying the record you want within the file. If you need random access I/O, use direct-access files. A common example of a random-access application is a database.

- Stream-Access Files

  Stream access I/O is a method of accessing a file without reference to a record structure. With stream access, a file is seen as a continuous sequence of bytes and is addressed by a positive integer starting from 1.

  To enable stream access, specify ACCESS='STREAM' in the OPEN statement for the file. You can use the STREAM= specifier in the INQUIRE statement to determine if STREAM is listed in the set of possible access methods for the file. A value of YES, NO, or UNKNOWN is returned.

  A file enabled for stream access is positioned by file storage units (normally bytes) starting at position 1. To determine the current position, use the POS= specifier in an INQUIRE statement for the unit. You can indicate a required position in a read or write statement with a POS= specifier.

  Stream access can be either formatted or unformatted.

  When connected for formatted stream access, an external file has the following characteristics:

  - The first file storage unit in the file is at position 1. The relationship between positions of successive file storage units is processor dependent; not all positive integers need to correspond to valid positions.
  - Some file storage units may contain record markers; this imposes a record structure on the file in addition to its stream structure. If there is no record marker at the end of the file, the final record is incomplete. Writing an empty record with no record marker has no effect.

When connected for unformatted stream access, an external file has the following characteristics:

- The first file storage unit in the file is at position 1. The position of each subsequent file storage unit is one greater than that of the preceding file storage unit.
- If it is possible to position the file, the file storage units do not need to be read or written in order of their position. For example, you may be able to write the file storage unit at position 2, even though the file storage unit at position 1 has not been written.
- Any file storage unit may be read from the file while it is connected to a unit, provided that the file storage unit has been written since the file was created, and a READ statement for this connection is allowed.
- You cannot use BACKSPACE in an unformatted stream.

File Records

Files may be composed of records. Each record is one entry in the file. It can be a line from a terminal or a logical record on a magnetic tape or disk file. All records within one file are of the same type.

In Fortran, the number of bytes transferred to a record must be less than or equal to the record length. One record is transferred for each unformatted `READWRITE` or `READ` statement. A formatted `WRITE` or statement can transfer more than one record using the slash (`/`) edit descriptor.

For binary files, a single `READ` or `WRITE` statement reads or writes as many records as needed to accommodate the number of bytes being transferred. On output, incomplete formatted records are padded with spaces. Incomplete unformatted and binary records are padded with undefined bytes (zeros).

Record Types

An I/O record is a collection of data items, called fields, that are logically related and are processed as a unit. The record type refers to the convention for storing fields in records.

The record type of the data within a file is not maintained as an attribute of the file. The results of using a record type other than the one used to create the file are indeterminate.

A number of record types are available, as shown in the following table. The table also lists the record overhead. This refers to bytes associated with each record that are used internally by the file system and are not available when a record is read or written. Knowing the record overhead helps when estimating the storage requirements for an application. Although the overhead bytes exist on the storage media, do not include them when specifying the record length with the RECL specifier in an OPEN statement.

Record Type	Available File Organizations and Portability Considerations	Record Overhead
Fixed-length	Relative or sequential file organizations.	None for sequential or for relative if the `-vms` (Linux OS and Mac OS X) or `/vms` (Windows OS) option was omitted. One byte for relative if the `vms` option was specified.
Variable-length	Sequential file organization only. The variable-length record type is generally the most portable record type across multi-vendor platforms.	Eight bytes per record.
Segmented	Sequential file organization only and only for unformatted sequential access. The segmented record type is unique to Intel Fortran and should not be used for portability with programs written in languages other than Fortran or for places where Intel Fortran is not used. However, because the segmented record type is unique to Intel Fortran products, formatted data in segmented files can be ported across Intel Fortran platforms.	Four bytes per record. One additional padding byte (space) is added if the specified record size is an odd number.
Stream (uses no record terminator)	Sequential file organization only.	None required.
Stream_CR (uses CR as record terminator)	Sequential file organization only.	One byte per record.
Stream_LF (uses LF as record terminator)	Sequential file organization only.	One byte per record.

Record Type	Available File Organizations and Portability Considerations	Record Overhead
Stream_CRLF (uses CR and LF as record terminator)	Sequential file organization only.	Two bytes per record.

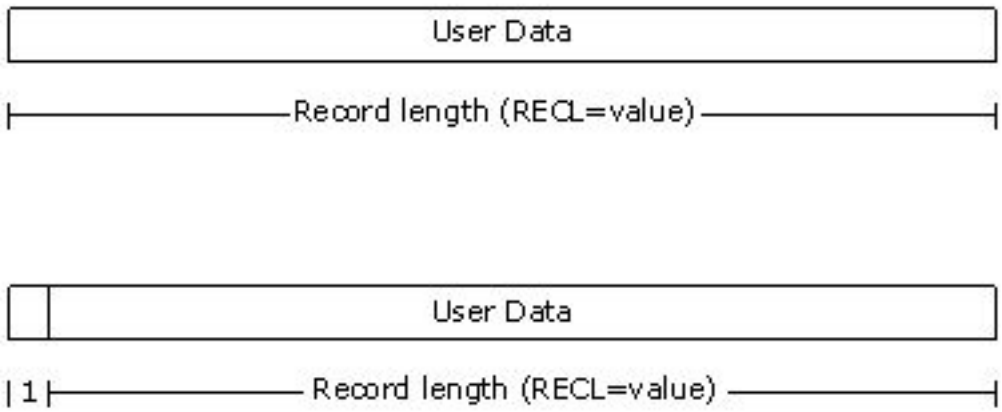
Fixed-Length Records

When you specify fixed-length records, you are specifying that all records in the file contain the same number of bytes. When you open a file that is to contain fixed-length records, you must specify the record size using the RECL keyword. A sequentially organized opened file for direct access must contain fixed-length records, to allow the record position in the file to be computed correctly.

For relative files, the layout and overhead of fixed-length records depends upon whether the program accessing the file was compiled using the `-vms` (Linux OS and Mac OS X) or `/vms` (Windows OS) option:

- For relative files where the vms option was omitted (the default), each record has no control information.
- For relative files where the vms option was specified, each record has one byte of control information at the beginning of the record.

The following figures show the record layout of fixed-length records. The first is for all sequential and relative files where the `vms` option was omitted. The second is for relative files where the `vms` option was specified.



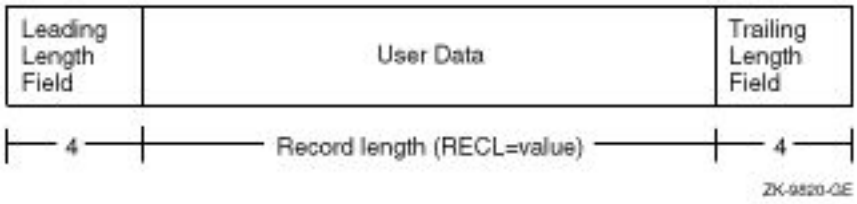
Variable-Length Records

Variable-length records can contain any number of bytes up to a specified maximum record length, and apply only to sequential files.

Variable-length records are prefixed and suffixed by 4 bytes of control information containing length fields. The trailing length field allows a BACKSPACE request to skip back over records efficiently. The 4-byte integer value stored in each length field indicates the number of data bytes (excluding overhead bytes) in that particular variable-length record.

The character count field of a variable-length record is available when you read the record by issuing a READ statement with a Q format descriptor. You can then use the count field information to determine how many bytes should be in an I/O list.

The record layout of variable-length records that are less than 2 gigabytes is shown below:

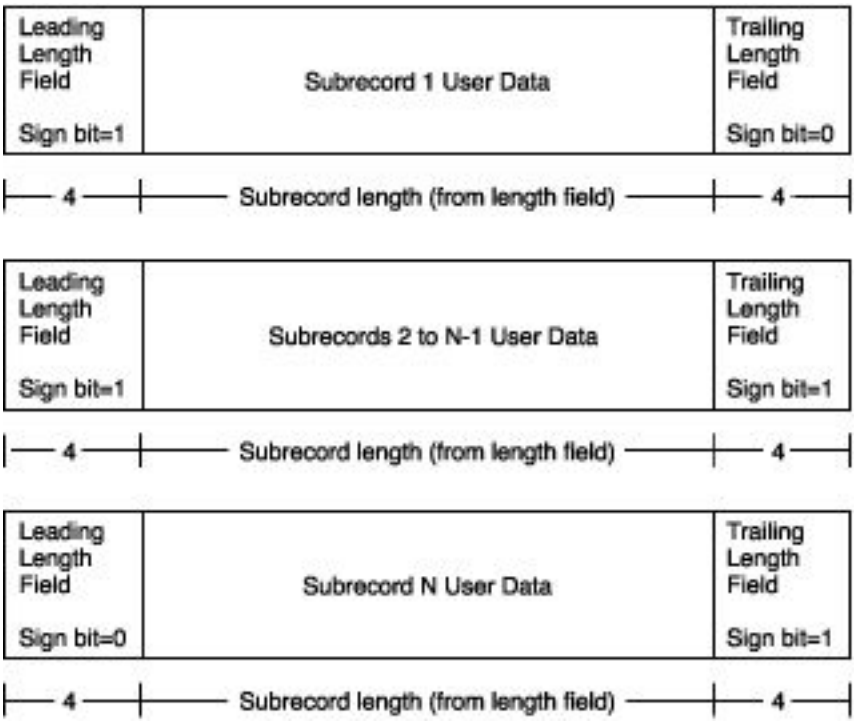


For a record length greater than 2,147,483,639 bytes, the record is divided into *subrecords*. The subrecord can be of any length from 1 to 2,147,483,639, inclusive.

The sign bit of the leading length field indicates whether the record is continued or not. The sign bit of the trailing length field indicates the presence of a preceding subrecord. The position of the sign bit is determined by the endian format of the file.

A subrecord that is continued has a leading length field with a sign bit value of 1. The last subrecord that makes up a record has a leading length field with a sign bit value of 0. A subrecord that has a preceding subrecord has a trailing length field with a sign bit value of 1. The first subrecord that makes up a record has a trailing length field with a sign bit value of 0. If the value of the sign bit is 1, the length of the record is stored in twos-complement notation.

The record layout of variable-length records that are greater than 2 gigabytes is shown below:



Files written with variable-length records by Intel Fortran programs usually cannot be accessed as text files. Instead, use the Stream_LF record format for text files with records of varying length.

Segmented Records

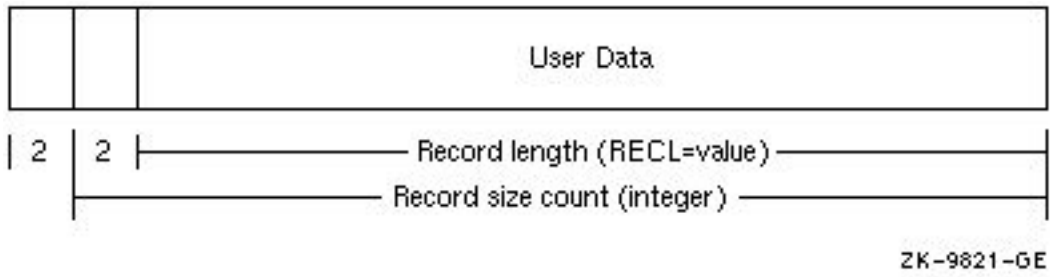
A segmented record is a single logical record consisting of one or more variable-length, unformatted records in a sequentially organized disk file. Unformatted data written to sequentially organized files using sequential access is stored as segmented records by default.

Segmented records are useful when you want to write exceptionally long records but cannot or do not wish to define one long variable-length record, perhaps because virtual memory limitations can prevent program execution. By using smaller, segmented records, you reduce the chance of problems caused by virtual memory limitations on systems on which the program may execute.

For disk files, the segmented record is a single logical record that consists of one or more segments. Each segment is a physical record. A segmented (logical) record can exceed the absolute maximum record length (2.14 billion bytes), but each segment (physical record) individually cannot exceed the maximum record length.

To access an unformatted sequential file that contains segmented records, specify FORM='UNFORMATTED' and RECORDTYPE='SEGMENTED' when you open the file.

As shown below, the layout of segmented records consists of 4 bytes of control information followed by the user data.



The control information consists of a 2-byte integer record length count (includes the 2 bytes used by the segment identifier), followed by a 2-byte integer segment identifier that identifies this segment as one of the following:

Identifier Value	Segment Identified
0	One of the segments between the first and last segments
1	First segment
2	Last segment
3	Only segment

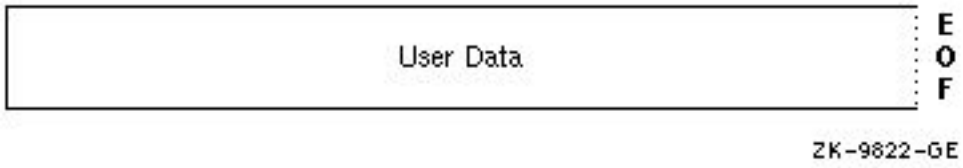
If the specified record length is an odd number, the user data will be padded with a single blank (one byte), but this extra byte is not added to the 2-byte integer record size count.

Avoid the segmented record type when the application requires that the same file be used for programs written in languages other than Intel Fortran and for non-Intel platforms.

Stream File Data

A stream file is not grouped into records and contains no control information. Stream files are used with CARRIAGECONTROL='NONE' and contain character or binary data that is read or written only to the extent of the variables specified on the input or output statement.

The layout of a stream file appears below.



Stream_CR, Stream_LF and Stream_CRLF Records

Stream_CR, Stream_LF, and Stream_CRLF records are variable-length records whose length is indicated by explicit record terminators embedded in the data, not by a count. These terminators are automatically added when you write records to a stream-type file and are removed when you read records.

Each variety uses either a different 1-byte or 2-byte record terminator:

- Stream_CR files use only a carriage-return as the terminator, so Stream_CR files must not contain embedded carriage-return characters.
- Stream_LF files use only a line-feed (new line) as the terminator, so Stream_LF files must not contain embedded line-feed (new line) characters. This is the usual operating system text file record type on Linux* OS and Mac OS* X systems.
- Stream_CRLF files use a carriage return/line-feed (new line) pair as the terminator, so Stream_CRLF files must not contain embedded carriage returns or line-feed (new line) characters. This is the usual operating system text file record type on Windows* systems.

Guidelines for Choosing a Record Type

Before you choose a record type, consider whether your application will use formatted or unformatted data. If you are using formatted data, you can choose any record type except segmented. If you are using unformatted data, avoid the Stream, Stream_CR, Stream_LF and Stream_CRLF record types.

The segmented record type can only be used for unformatted sequential access with sequential files. You should not use segmented records for files that are read by programs written in languages other than Intel Fortran.

The Stream, Stream_CR, Stream_LF, Stream_CRLF and segmented record types can be used only with sequential files.

The default record type (RECORDTYPE) depends on the values for the ACCESS and FORM specifiers for the OPEN statement. (The RECORDTYPE= specifier is ignored for stream access.)

The record type of the file is not maintained as an attribute of the file. The results of using a record type other than the one used to create the file are indeterminate.

An I/O record is a collection of fields (data items) that are logically related and are usually processed as a unit.

Unless you specify nonadvancing I/O (ADVANCE specifier), each Intel Fortran I/O statement transfers at least one record.

Specifying the Line Terminator for Formatted Files

Use the FOR_FMT_TERMINATOR environment variable to specify the line terminator value used for Fortran formatted files with no explicit RECORDTYPE= specifier.

The FOR_FMT_TERMINATOR environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units continues for the rest of the execution.

You can specify the numbers of the units to have a specific record terminator. The READ/WRITE statements that use these unit numbers will now use the specified record terminators. Other READ/WRITE statements will work in the usual way.

A RECORDTYPE=specifier on an OPEN statement overrides the value set by FOR_FMT_TERMINATOR. The FOR_FMT_TERMINATOR value is ignored for ACCESS='STREAM' files.

General Syntax for FOR_FMT_TERMINATOR

The syntax for this environment variable is as follows:

```
FOR_FMT_TERMINATOR=MODE[:ULIST][;MODE[:ULIST]]
```

where:

```
MODE=CR | LF | CRLF
ULIST = U | ULIST,U
U = decimal | decimal - decimal
```

- `MODE` specifies the record terminator to be used. The keyword `CR` means to terminate records with a carriage return. The keyword `LF` means to terminate records with a line feed; this is the default on Linux OS and Mac OS X systems. The keyword `CRLF` means to terminate records with a carriage return/line feed pair; this is the default on Windows systems.
- Each list member `U` is a simple unit number or a number of units as a range. The number of list members is limited to 64.
- `decimal` is a non-negative decimal number less than 232.

No spaces are allowed inside the FOR_FMT_TERMINATOR value.

On Linux* systems, the command line for the variable setting in the shell is:

```
Sh: export FOR_FMT_TERMINATOR=MODE:ULIST
```

NOTE. The environment variable value should be enclosed in quotes if the semicolon is present.

Example:

The following specifies that all input/output operations on unit numbers 10, 11, and 12 have records terminated with a carriage return/line feed pair:

```
FOR_FMT_TERMINATOR=CRLF:10-12
```

Record Length

Use the RECL specifier to specify the record length.

The units used for specifying record length depend on the form of the data:

- Formatted files (FORM= 'FORMATTED'): Specify the record length in bytes.
- Unformatted files (FORM= 'UNFORMATTED'): Specify the record length in 4-byte units, unless you specify the `-assume byterecl` (Linux OS and Mac OS X) or `/assume:byterecl` (Windows OS) option to request 1-byte units.

For all but variable-length sequential records on 64-bit addressable systems, the maximum record length is 2.147 billion bytes (2,147,483,647 minus the bytes for record overhead). For variable-length sequential records on 64-bit addressable systems, the theoretical maximum record length is about 17,000 gigabytes. When considering very large record sizes, also consider limiting factors such as system virtual memory.

NOTE. The RECL specifier is ignored for stream access.

Record Access

Record access refers to how records will be read from or written to a file, regardless of the file's organization. Record access is specified each time you open a file; it can be different each time. The type of record access permitted is determined by the combination of file organization and record type.

For instance, you can:

- Add records to a sequential file with ORGANIZATION= 'SEQUENTIAL' and POSITION= 'APPEND' (or use ACCESS= 'APPEND').
- Add records sequentially by using multiple WRITE statements, close the file, and then open it again with ORGANIZATION= 'SEQUENTIAL' and ACCESS= 'SEQUENTIAL' (or ACCESS= 'DIRECT' if the sequential file has fixed-length records).

Sequential Access

Sequential access transfers records sequentially to or from files or I/O devices such as terminals. You can use sequential I/O with any type of supported file organization and record type.

If you select sequential access mode for files with sequential or relative organization, records are written to or read from the file starting at the beginning of the file and continuing through it, one record after another. A particular record can be retrieved only after all of the records preceding it have been read; new records can be written only at the end of the file.

Direct Access

Direct access transfers records selected by record number to and from either sequential files stored on disk with a fixed-length record type or relative organization files.

If you select direct access mode, you can determine the order in which records are read or written. Each READ or WRITE statement must include the relative record number, indicating the record to be read or written.

You can directly access a sequential disk file only if it contains fixed-length records. Because direct access uses cell numbers to find records, you can enter successive READ or WRITE statements requesting records that either precede or follow previously requested records. For example, the first of the following statements reads record 24; the second reads record 10:

```
READ (12,REC=24) I
READ (12,REC=10) J
```

Stream Access

Stream access transfers bytes from records sequentially until a record terminator is found or a specified number of bytes have been read or written. Formatted stream records are terminated with a new line character; unformatted stream data contains no record terminators. Bytes can be read from or written to a file by byte position, where the first byte of the file is position 1. An example follows:

```
OPEN (UNIT=12, ACCESS='STREAM')
READ (12) I, J, K              ! start at the first byte of the file
READ (12, POS=200) X, Y       ! then read staring at byte 200
READ (12) A, B            ! then read starting where the previous READ stopped
```

The POS= specifier on INQUIRE can be used to determine the current byte position in the file.

NOTE. The RECORDTYPE= specifier is ignored for stream access.

Limitations of Record Access by File Organization and Record Type

You can use sequential and direct access modes on sequential and relative files. However, direct access to a sequential organization file can only be done if the file resides on disk and contains fixed-length records.

The table below summarizes the types of access permitted for the various combinations of file organizations and record types.

Record Type	Sequential Access?	Direct Access?
Sequential file organization		
Fixed	Yes	Yes
Variable	Yes	No
Segmented	Yes	No

Record Type	Sequential Access?	Direct Access?
Stream	Yes	No
Stream_CR	Yes	No
Stream_LF	Yes	No
Stream_CRLF	Yes	No
Relative file organization		
Fixed	Yes	Yes

NOTE. Direct access and relative files require that the file resides on a disk device.

Record Transfer

I/O statements transfer all data as records. The amount of data that a record can contain depends on the following circumstances:

- With formatted I/O (except for fixed-length records), the number of items in the I/O statement and its associated format specifier jointly determine the amount of data to be transferred.
- With namelist and list-directed output, the items listed in the NAMELIST statement or I/O statement list (in conjunction with the NAMELIST or list-directed formatting rules) determine the amount of data to be transferred.
- With unformatted I/O (except for fixed-length records), the I/O statement alone specifies the amount of data to be transferred.
- When you specify fixed-length records (RECORDTYPE= 'FIXED'), all records are the same size. If the size of an I/O record being written is less than the record length (RECL), extra bytes are added (padding).

Typically, the data transferred by an I/O statement is read from or written to a single record. It is possible, however, for a single I/O statement to transfer data from or to more than one record, depending on the form of I/O used.

Input Record Transfer

When using advancing I/O, if an input statement specifies fewer data fields (less data) than the record contains, the remaining fields are ignored.

If an input statement specifies more data fields than the record contains, one of the following occurs:

- For formatted input using advancing I/O, if the file was opened with PAD='YES', additional fields are read as spaces. If the file is opened with PAD='NO', an error occurs (the input statement should not specify more data fields than the record contains).
- For formatted input using nonadvancing I/O (ADVANCE='NO'), an end-of-record (EOR) condition is returned. If the file was opened with PAD='YES', additional fields are read as spaces.
- For list-directed input, another record is read.
- For NAMELIST input, another record is read.
- For unformatted input, an error occurs.

Output Record Transfer

If an output statement specifies fewer data fields than the record contains (less data than required to fill a record), the following occurs:

- With fixed-length records (RECORDTYPE= 'FIXED'), all records are the same size. If the size of an I/O record being written is less than the record length (RECL), extra bytes are added (padding) in the form of spaces (for a formatted record) or zeros (for an unformatted record).
- With other record types, the fields present are written and those omitted are not written (might result in a short record).

If the output statement specifies more data than the record can contain, an error occurs, as follows:

- With formatted or unformatted output using fixed-length records, if the items in the output statement and its associated format specifier result in a number of bytes that exceeds the maximum record length (RECL), an error occurs.
- With formatted or unformatted output not using fixed-length records, if the items in the output statement and its associated format specifier result in a number of bytes that exceeds the maximum record length (RECL), the Intel Fortran RTL attempts to increase the RECL value and write the longer record. To obtain the RECL value, use an INQUIRE statement.

- For list-directed output and namelist output, if the data specified exceeds the maximum record length (RECL), another record is written.

Specifying Default Pathnames and File Names

Intel Fortran provides a number of ways of specifying all or part of a file specification (directory and file name). The following list uses the Linux* pathname `/usr/proj/testdata` as an example:

- The FILE specifier in an OPEN statement typically specifies only a file name (such as testdata) or contains both a directory and file name (such as `/usr/proj/testdata`).
- The DEFAULTFILE specifier in an OPEN statement typically specifies a pathname that contains only a directory (such as `/usr/proj/`) or both a directory and file name (such as `/usr/proj/testdata`).
- If you used an implied OPEN or if the FILE specifier in an OPEN statement did not specify a file name, you can use an environment variable to specify a file name or a pathname that contains both a directory and file name.

Examples of Applying Default Pathnames and File Names

For example, for an implied OPEN of unit number 3, Intel Fortran will check the environment variable FORT3. If the environment variable FORT3 is set, its value is used. If it is not set, the system supplies the file name `fort.3`.

In the following table, assume the current directory is `/usr/smith` and the I/O uses unit 1, as in the statement READ (1,100).

OPEN FILE value	OPEN DEFAULTFILE value	FORT1 environment variable value	Resulting pathname
not specified	not specified	not specified	/usr/smith/fort.1
not specified	not specified	test.dat	/usr/smith/test.dat
not specified	not checked	/usr/tmp/t.dat	/usr/tmp/t.dat
not specified	/tmp	not specified	/tmp/fort.1
not specified	/tmp	testdata	/tmp/testdata
not specified	/usr	lib/testdata	/usr/lib/testdata

OPEN FILE value	OPEN DEFAULTFILE value	FORT1 environment variable value	Resulting pathname
file.dat	/usr/group	not checked	/usr/group/file.dat
/tmp/file.dat	not checked	not checked	/tmp/file.dat
file.dat	not specified	not checked	/usr/smith/file.dat

When the resulting file pathname begins with a tilde character (~), C-shell-style pathname substitution is used (regardless of what shell is being used), such as a top-level directory (below the root). For additional information on tilde pathname substitution, see csh(1).

Rules for Applying Default Pathnames and File Names

Intel Fortran determines the file name and the directory path based on certain rules. It determines a file name string as follows:

- If the FILE specifier is present, its value is used.
- If the FILE specifier is not present, Intel Fortran examines the corresponding environment variable. If the corresponding environment variable is set, that value is used. If the corresponding environment variable is not set, a file name in the form fort. `n` is used.

Once Intel Fortran determines the resulting file name string, it determines the directory (which optionally precedes the file name) as follows:

- If the resulting file name string contains an absolute pathname, it is used and the DEFAULTFILE specifier, environment variable, and current directory values are ignored.
- If the resulting file name string does not contain an absolute pathname, Intel Fortran examines the DEFAULTFILE specifier and current directory value: If the corresponding environment variable is set and specifies an absolute pathname, that value is used. Otherwise, the DEFAULTFILE specifier value, if present, is used. If the DEFAULTFILE specifier is not present, Intel Fortran uses the current directory as an absolute pathname.

Opening Files: OPEN Statement

To open a file, you can use a preconnected file (such as for terminal output) or can open a file with an OPEN statement. The OPEN statement lets you specify the file connection characteristics and other information.

OPEN Statement Specifiers

The OPEN statement connects a unit number with an external file and allows you to explicitly specify file attributes and run-time options using OPEN statement specifiers. Once you open a file, you should close it before opening it again unless it is a preconnected file.

If you open a unit number that was opened previously (without being closed), one of the following occurs:

- If you specify a file specification that does not match the one specified for the original open, the Intel Fortran run-time system closes the original file and then opens the second file. This resets the current record position for the second file.
- If you specify a file specification that matches the one specified for the original open, the file is reconnected without the internal equivalent of the CLOSE and OPEN. This lets you change one or more OPEN statement run-time specifiers while maintaining the record position context.

You can use the INQUIRE statement to obtain information about whether or not a file is opened by your program.

Especially when creating a new file using the OPEN statement, examine the defaults (see the description of the OPEN statement in the Intel Fortran Language Reference Manual) or explicitly specify file attributes with the appropriate OPEN statement specifiers.

Specifiers for File and Unit Information

These specifiers identify file and unit information:

- UNIT specifies the logical unit number.
- FILE (or NAME) and DEFAULTFILE specify the directory and/or file name of an external file.
- STATUS or TYPE indicates whether to create a new file, overwrite an existing file, open an existing file, or use a scratch file.
- STATUS or DISPOSE specifies the file existence status after CLOSE.

Specifiers for File and Record Characteristics

These specifiers identify file and record characteristics:

- ORGANIZATION indicates the file organization (sequential or relative).
- RECORDTYPE indicates which record type to use.

- FORM indicates whether records are formatted or unformatted.
- CARRIAGECONTROL indicates the terminal control type.
- RECL or RECORDSIZE specifies the record size.

Specifier for Special File Open Routine

USEROPEN names the routine that will open the file to establish special context that changes the effect of subsequent Intel Fortran I/O statements.

Specifiers for File Access, Processing, and Position

These specifiers identify file access, processing, and position:

- ACCESS indicates the access mode (direct, sequential, or stream).
- SHARED sets file locking for shared access. Indicates that other users can access the same file.
- NOSHARED sets file locking for exclusive access. Indicates that other users who use file locking mechanisms cannot access the same file.
- SHARE specifies shared or exclusive access; for example, SHARE='DENYNONE' or SHARE='DENYRW'.
- POSITION indicates whether to position the file at the beginning of file, before the end-of-file record, or leave it as is (unchanged).
- ACTION or READONLY indicates whether statements will be used to only read records, only write records, or both read and write records.
- MAXREC specifies the maximum record number for direct access.
- ASSOCIATEVARIABLE specifies the variable containing the next record number for direct access.
- ASYNCHRONOUS specifies whether input/output should be performed asynchronously.

Specifiers for Record Transfer Characteristics

These specifiers identify record transfer characteristics:

- BLANK indicates whether to ignore blanks in numeric fields.
- DELIM specifies the delimiter character for character constants in list-directed or namelist output.

- PAD, when reading formatted records, indicates whether padding characters should be added if the item list and format specification require more data than the record contains.
- BUFFERED indicates whether buffered or non-buffered I/O should be used.
- BLOCKSIZE specifies the block physical I/O buffer size.
- BUFFERCOUNT specifies the number of physical I/O buffers.
- CONVERT specifies the format of unformatted numeric data.

Specifiers for Error-Handling Capabilities

These specifiers are used for error handling:

- ERR specifies a label to branch to if an error occurs.
- IOSTAT specifies the integer variable to receive the error (IOSTAT) number if an error occurs.

Specifier for File Close Action

DISPOSE identifies the action to take when the file is closed.

Specifying File Locations in an OPEN Statement

You can use the FILE and DEFAULTFILE specifiers of the OPEN statement to specify the complete definition of a particular file to be opened on a logical unit. (The Language Reference Manual describes the OPEN statement in greater detail.)

For example:

```
OPEN (UNIT=4, FILE='/usr/users/smith/test.dat', STATUS='OLD')
```

The file `test.dat` in directory `/usr/users/smith` is opened on logical unit 4. No defaults are applied, because both the directory and file name were specified. The value of the FILE specifier can be a character constant, variable, or expression.

In the following interactive example, the user supplies the file name and the DEFAULTFILE specifier supplies the default values for the full pathname string. The file to be opened is located in `/usr/users/smith` and is concatenated with the file name typed by the user into the variable DOC:

```
CHARACTER(LEN=9) DOC
WRITE (6,*)  'Type file name '
READ (5,*) DOC
OPEN (UNIT=2, FILE=DOC, DEFAULTFILE='/usr/users/smith',STATUS='OLD')
```

A slash (backslash on Windows systems) is appended to the end of the default file string if it does not have one.

Obtaining File Information: INQUIRE Statement

The INQUIRE statement returns information about a file and has the following forms:

- Inquiry by unit
- Inquiry by file name
- Inquiry by output item list
- Inquiry by directory

Inquiry by Unit

An inquiry by unit is usually done for an opened (connected) file. An inquiry by unit causes the Intel Fortran RTL to check whether the specified unit is connected or not. One of the following occurs, depending on whether the unit is connected or not:

If the unit is connected:

- The EXIST and OPENED specifier variables indicate a true value.
- The pathname and file name are returned in the NAME specifier variable (if the file is named).
- Other information requested on the previously connected file is returned.
- Default values are usually returned for the INQUIRE specifiers also associated with the OPEN statement.
- The RECL value unit for connected formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

If the unit is not connected:

- The OPENED specifier indicates a false value.
- The unit NUMBER specifier variable is returned as a value of `-1`.
- Any other information returned will be undefined or default values for the various specifiers.

For example, the following INQUIRE statement shows whether unit 3 has a file connected (OPENED specifier) in logical variable I_OPENED, the name (case-sensitive) in character variable I_NAME, and whether the file is opened for READ, WRITE, or READWRITE access in character variable I_ACTION:

```
INQUIRE (3, OPENED=I_OPENED, NAME=I_NAME, ACTION=I_ACTION)
```

Inquiry by File Name

An inquiry by name causes the Intel Fortran RTL to scan its list of open files for a matching file name. One of the following occurs, depending on whether a match occurs or not:

If a match occurs:

- The EXIST and OPENED specifier variables indicate a true value.
- The pathname and file name are returned in the NAME specifier variable.
- The UNIT number is returned in the NUMBER specifier variable.
- Other information requested on the previously connected file is returned.
- Default values are usually returned for the INQUIRE specifiers also associated with the OPEN statement.
- The RECL value unit for connected formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

If no match occurs:

- The OPENED specifier variable indicates a false value.
- The unit NUMBER specifier variable is returned as a value of `-1`.
- The EXIST specifier variable indicates (true or false) whether the named file exists on the device or not.
- If the file does exist, the NAME specifier variable contains the pathname and file name.
- Any other information returned will be default values for the various specifiers, based on any information specified when calling INQUIRE.

The following INQUIRE statement returns whether the file named log_file is connected in logical variable I_OPEN, whether the file exists in logical variable I_EXIST, and the unit number in integer variable I_NUMBER:

```
INQUIRE (FILE='log_file', OPENED=I_OPEN, EXIST=I_EXIST, NUMBER=I_NUMBER)
```

Inquiry by Output Item List

Unlike inquiry by unit or inquiry by name, inquiry by output item list does not attempt to access any external file. It returns the length of a record for a list of variables that would be used for unformatted WRITE, READ, and REWRITE statements. The following INQUIRE statement returns the maximum record length of the variable list in variable I_RECLENGTH. This variable is then used to specify the RECL value in the OPEN statement:

```
INQUIRE (IOLENGTH=I_RECLENGTH) A, B, H
OPEN (FILE='test.dat', FORM='UNFORMATTED', RECL=I_RECLENGTH, UNIT=9)
```

For an unformatted file, the IOLENGTH value is returned using 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

Inquiry by Directory

An inquiry by directory verifies that a directory exists.

If the directory exists:

- The EXIST specifier variable indicates a true value.
- The full directory pathname is returned in the DIRSPEC specifier variable.

If the directory does not exist:

- The EXIST specified variable indicates a false value.
- The value of the DIRSPEC specifier variable is unchanged.

For example, the following INQUIRE statement returns the full directory pathname:

```
LOGICAL        ::L_EXISTS
CHARACTER (255)::C_DIRSPEC
INQUIRE (DIRECTORY=".", DIRSPEC=C_DIRSPEC, EXIST=L_EXISTS)
```

The following INQUIRE statement verifies that a directory does not exist:

```
INQUIRE (DIRECTORY="I-DO-NOT-EXIST",
EXIST=L_EXISTS)
```

Closing Files: CLOSE Statement

Usually, any external file opened should be closed by the same program before it completes. The CLOSE statement disconnects the unit and its external file. You must specify the unit number (UNIT specifier) to be closed.

You can also specify:

- Whether the file should be deleted or kept (STATUS specifier)
- Error handling information (ERR and IOSTAT specifiers)

To delete a file when closing it:

- In the OPEN statement, specify the ACTION keyword (such as ACTION='READ'). Avoid using the READONLY keyword, because a file opened using the READONLY keyword cannot be deleted when it is closed.
- In the CLOSE statement, specify the keyword STATUS='DELETE'.

If you opened an external file and did an inquire by unit, but do not like the default value for the ACCESS specifier, you can close the file and then reopen it, explicitly specifying the ACCESS desired.

There usually is no need to close preconnected units. Internal files are neither opened nor closed.

Record I/O Statement Specifiers

After you open a file or use a preconnected file, you can use the following statements:

- READ, WRITE, ACCEPT, and PRINT to perform record I/O.
- BACKSPACE, ENDFILE, and REWIND to set record position within the file.
- DELETE, REWRITE, TYPE, and FIND to perform various operations.

The record I/O statement must use the appropriate record I/O form (formatted, list-directed, namelist, or unformatted).

You can use the following specifiers with the READ and WRITE record I/O statements:

- UNIT specifies the unit number to or from which input or output will occur.
- END specifies a label to branch to if end-of-file occurs; only applies to input statements on sequential files.
- ERR specifies a label to branch to if an error occurs.
- IOSTAT specifies an integer variable to contain the error number if an error occurs.
- FMT specifies a label of a FORMAT statement or character data specifying a FORMAT.
- NML specifies the name of a NAMELIST.
- REC specifies a record number for direct access.

When using nonadvancing I/O, use the ADVANCE, EOR, and SIZE specifiers.

When using the REWRITE statement, you can use the UNIT, FMT, ERR, and IOSTAT specifiers.

File Sharing on Linux* OS and Mac OS* X Systems

Depending on the value specified by the ACTION (or READONLY) specifier in the OPEN statement, the file will be opened by your program for reading, writing, or both reading and writing records. This simply checks that the program itself executes the type of statements intended.

File locking mechanisms allow users to enable or restrict access to a particular file when that file is being accessed by another process.

Intel® Fortran file locking features provide three file access modes:

- Implicit Shared mode, which occurs when no mode is specified. This is also called No Locking.
- Explicit Shared mode, when all cooperating processes have access to a file. This mode is set in the OPEN statement by the SHARED specifier or the SHARE='DENYNONE' specifier.
- Exclusive mode, when only one process has access to a file. This mode is set in the OPEN statement by the NOSHARED specifier or the SHARE='DENYRW' specifier.

The file locking mechanism looks for explicit setting of the corresponding specifier in the OPEN statement. Otherwise, the Fortran run time does not perform any setting or checking for file locking and the process can access the file regardless of the fact that other processes have already opened or locked the file.

Example 1: Implicit Shared Mode (No Locking)

Process 1 opens the file without a specifier, resulting in no locking.

Process 2 now tries to open the file:

- It gains access regardless of the mode it is using.

Example 2: Explicit Shared Mode

Process 1 opens the file with Explicit Shared mode.

Process 2 now tries to open the file:

- If process 2 opens the file with Explicit Shared mode or Implicit Shared (No Locking) mode, it gets access to the file.
- If process 2 opens the file with Exclusive mode, it receives an error.

Example 3: Exclusive Mode

Process 1 opens the file with Exclusive mode.

Process 2 now tries to open the file:

- If process 2 opens the file with Implicit Shared (No Locking) mode, it gets access to the file.
- If process 2 opens the file with Explicit Shared or Exclusive mode, it receives an error.

The Fortran runtime does not coordinate file entry updates during cooperative access. The user needs to coordinate access times among cooperating processes to handle the possibility of simultaneous WRITE and REWRITE statements on the same record positions.

Specifying the Initial Record Position

When you open a disk file, you can use the OPEN statement POSITION specifier to request one of the following initial record positions within the file:

- The initial position before the first record (POSITION='REWIND'). A sequential access READ or WRITE statement will read or write the first record in the file.
- A point beyond the last record in the file (POSITION='APPEND'), just before the end-of-file record, if one exists. For a new file, this is the initial position before the first record (same as 'REWIND'). You might specify 'APPEND' before you write records to an existing sequential file using sequential access.
- The current position (POSITION='ASIS') . This is usually used only to maintain the current record position when reconnecting a file. The second OPEN specifies the same unit number and specifies the same file name (or omits it), which leaves the file open, retaining the current record position. However, if the second OPEN specifies a different file name for the same unit number, the current file will be closed and the different file will be opened.

The following I/O statements allow you to change the current record position:

- REWIND sets the record position to the initial position before the first record. A sequential access READ or WRITE statement would read or write the first record in the file.
- BACKSPACE sets the record position to the previous record in a file. Using sequential access, if you wrote record 5, issued a BACKSPACE to that unit, and then read from that unit, you would read record 5.
- ENDFILE writes an end-of-file marker. This is typically done after writing records using sequential access just before you close the file.

Unless you use nonadvancing I/O, reading and writing records usually advances the current record position by one record. More than one record might be transferred using a single record I/O statement.

Advancing and Nonadvancing Record I/O

After you open a file, if you omit the ADVANCE specifier (or specify ADVANCE= 'YES') in READ and WRITE statements, advancing I/O (normal `Fortran I/O`) will be used for record access. When using advancing I/O:

- Record I/O statements transfer one entire record (or multiple records).
- Record I/O statements advance the current record position to a position before the next record.

You can request nonadvancing I/O for the file by specifying the ADVANCE= 'NO' specifier in a READ and WRITE statement. You can use nonadvancing I/O only for sequential access to external files using formatted I/O (not list-directed or namelist).

When you use nonadvancing I/O, the current record position does not change, and part of the record might be transferred, unlike advancing I/O where one or more entire records are always transferred.

You can alternate between advancing and nonadvancing I/O by specifying different values for the ADVANCE specifier ('YES' and 'NO') in the READ and WRITE record I/O statements.

When reading records with either advancing or nonadvancing I/O, you can use the `END specifier` to branch to a specified label when the end of the file is read.

Because nonadvancing I/O might not read an entire record, it also supports an `EOR specifier` to branch to a specified label when the end of the record is read. If you omit the EOR and the IOSTAT specifiers when using nonadvancing I/O, an error results when the end-of-record is read.

When using nonadvancing input, you can use the SIZE specifier to return the number of characters read. For example, in the following READ statement, SIZE=X (where variable X is an integer) returns the number of characters read in X and an end-of-record condition causes a branch to label 700:

```
150 FORMAT (F10.2, F10.2, I6)
    READ (UNIT=20, FMT=150, SIZE=X, ADVANCE='NO', EOR=700) A, F, I
```

User-Supplied OPEN Procedures: USEROPEN Specifier

You can use the USEROPEN specifier in an Intel Fortran OPEN statement to pass control to a routine that directly opens a file. The called routine can use system calls or library routines to open the file and establish special context that changes the effect of subsequent Intel Fortran I/O statements.

The Intel Fortran RTL I/O support routines call the USEROPEN function in place of the system calls usually used when the file is first opened for I/O. The USEROPEN specifier in an OPEN statement specifies the name of a function to receive control. The called function must open the file (or pipe) and return the file descriptor of the file when it returns control to the RTL.

When opening the file, the called function usually specifies options different from those provided by a normal OPEN statement.

You can obtain the file descriptor from the Intel Fortran RTL for a specific unit number with the getfd routine.

Although the called function can be written in other languages (such as Fortran), C is usually the best choice for making system calls, such as open or create.

Syntax and Behavior of the USEROPEN Specifier

The USEROPEN specifier for the OPEN statement has the form:

```
USEROPEN = function-name
```

function-name represents the name of an external function. In the calling program, the function must be declared in an EXTERNAL statement. For example, the following Intel Fortran code might be used to call the USEROPEN procedure UOPEN (known to the linker as uopen_):

```
EXTERNAL  UOPEN
INTEGER   UOPEN
.
.
.
OPEN (UNIT=10, FILE='/usr/test/data', STATUS='NEW', USEROPEN=UOPEN)
```

During the OPEN statement, the uopen_function receives control. The function opens the file, may perform other operations, and subsequently returns control (with the file descriptor) to the RTL.

If the USEROPEN function is written in C, declare it as a C function that returns a 4-byte integer (int) result to contain the file descriptor. For example:

```
int   uopen_ (          (1)
char  *file_name,       (2)
int   *open_flags,      (3)
int   *create_mode,     (4)
int   *lun,             (5)
int   file_length);     (6)
```

The function definition and the arguments passed from the Intel Fortran RTL are as follows:

1. The function must be declared as a 4-byte integer (int).
2. The first argument is the pathname (includes the file name) to be opened.

3. The open flags are described in the header file `/usr/include/sys/file.h` or open(2).
4. The create mode (protection needed when creating a Linux* OS-style file) is described in open(2).
5. The fourth argument is the logical unit number.
6. The fifth (last) argument is the pathname length (hidden length argument of the pathname).

Of the arguments, the open system call (see open(2)) requires the passed pathname, the open flags (that define the type access needed, whether the file exists, and so on), and the create mode. The logical unit number specified in the OPEN statement is passed in case the USEROPEN function needs it. The hidden length of the pathname is also passed.

When creating a new file, the create system call might be used in place of open (see create(2)). You can usually use other appropriate system calls or library routines within the USEROPEN function.

In most cases, the USEROPEN function modifies the open flags argument passed by the Intel Fortran RTL or uses a new value before the open (or create) system call. After the function opens the file, it must return control to the RTL.

If the USEROPEN function is written in Fortran, declare it as a FUNCTION with an INTEGER (KIND=4) result, perhaps with an interface block. In any case, the called function must return the file descriptor as a 4-byte integer to the RTL.

If your application requires that you use C to perform the file open and close, as well as all record operations, call the appropriate C procedure from the Intel Fortran program without using the Fortran OPEN statement.

Restrictions of Called USEROPEN Functions

The Intel Fortran RTL uses exactly one file descriptor per logical unit, which must be returned by the called function. Because of this, only certain system calls or library routines can be used to open the file.

System calls and library routines that do not return a file descriptor include mknod (see mknod(2)) and fopen (see fopen(3)). For example, the fopen routine returns a file pointer instead of a file descriptor.

Example USEROPEN Program and Function

The following Intel Fortran code calls the USEROPEN function named UOPEN:

```
EXTERNAL  UOPEN
INTEGER   UOPEN
.
.
.
OPEN (UNIT=1,FILE='ex1.dat',STATUS='NEW',USEROPEN=UOPEN,
ERR=9,IOSTAT=errnum)
```

If UOPEN is a Fortran function, its name is decorated appropriately for Fortran.

Likewise, if UOPEN is a C function, its name is decorated appropriately for C, as long as the following line is included in the above code:

```
!DEC$ATTRIBUTES C::UOPEN
```

Compiling and Linking the C and Intel Fortran Programs

Use the icc or icl command to compile the called `uopen` C function `uopen.c` and the `ifort` command to compile the Intel Fortran calling program `ex1.f`. The same ifort command also links both object files by using the appropriate libraries:

```
icc -c uopen.c (Linux* OS)
icl -c uopen.c (Windows* OS)
ifort ex1.f uopen.o
```

Example Source Code

```
      program UserOpenSample
!DEC$ FREEFORM
      IMPLICIT NONE
      EXTERNAL UOPEN
      INTEGER(4) UOPEN
      CHARACTER*10 :: FileName="UOPEN.DAT"
      INTEGER*4 :: IOS
      Character*255 :: InqFullName
      Character*100 :: InqFileName
      Integer :: InqLun
      Character*30 :: WriteOutBuffer="Write One Record to the File. "
      Character*30 :: ReadInBuffer  ="??????????????????????????????"
110   FORMAT( X,A, ": Created (iostat=",I0,")")
115   FORMAT( X,A, ": Creation Failed (iostat=",I0,")")
120   FORMAT( X,A, ": ERROR: INQUIRE Returned Wrong FileName")
130   FORMAT( X,A, ": ERROR: ReadIn and WriteOut Buffers Do Not Match")
190   FORMAT( X,A, ": Completed.")
      WRITE(*,'(X,"Test the USEROPEN Facility of Open")')
      OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='REPLACE',USEROPEN=UOPEN, &
```

```
            IOSTAT=ios, ACTION='READWRITE')

!     When the OPEN statement is executed,
!     the UOPEN function receives control.
!     The function opens the file by calling CreateFile( ),
!     performs whatever operations were specified, and subsequently
!     returns control (with the handle returned by CreateFile( ))
!     to the calling Fortran program.
      IF (IOS .EQ. 0)  THEN
         WRITE(*,110) TRIM(FileName), IOS
         INQUIRE(10, NAME=InqFullName)
         CALL ParseForFileName(InqFullName,InqFileName)
         IF (InqFileName .NE. FileName) THEN
            WRITE(*,120) TRIM(FileName)
         END IF
      ELSE
         WRITE(*,115) TRIM(FileName), IOS
         GOTO 9999
      END IF
      WRITE(10,*) WriteOutBuffer
      REWIND(10)
      READ(10,*)
 ReadInBuffer
      IF (ReadinBuffer .NE. WriteOutbuffer) THEN
         WRITE(*,130) TRIM(FileName)

!++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
! Here is the UOPEN function for WIN32:
!
! The UOPEN function is declared to use the cdecl calling convention,
! so it matches the Fortran rtl declaration of a useropen routine.
!
! The following function definition and arguments are passed from the Intel
! Fortran Run-time Library to the function named in USEROPEN:
!
! The first 7 arguments correspond to the CreateFile( ) api arguments.
! The value of these arguments is set according the caller's OPEN( )
! arguments:
!
! FILENAME
!      Is the address of a null terminated character string that
!      is the name of the file.
! DESIRED_ACCESS
!      Is the desired access (read-write) mode passed by reference.
! SHARE_MODE
```

```
!      Is the file sharing mode passed by reference.
! A_NULL
!      Is always null. The Fortran runtime library always passes a NULL
!      for the pointer to a SECURITY_ATTRIBUTES structure in its
!      CreateFile( ) call.
! CREATE_DISP
!      Is the creation disposition specifying what action to take on files
!      that exist, and what action to take on files
!      that do not exist. It is passed by reference.
! FLAGS_ATTR
!      Specifies the file attributes and flags for the file. It is passed
!      by reference.
! B_NULL
!      Is always null. The Fortran runtime library always passes a NULL
!      for the handle to a template file in it's CreateFile( ) call.
! The last 2 arguments are the Fortran unit number and length of the
! file name:
! UNIT
!      Is the Fortran unit number on which this OPEN is being done. It is
!      passed by reference.
! FLEN
!      Is the length of the file name, not counting the terminating null,
!      and passed by value.
!++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

Microsoft Fortran PowerStation Compatible Files

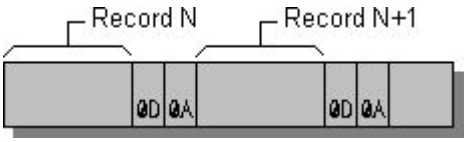
When using the `-fpscomp` (Linux OS and Mac OS X) or `/fpscomp` (Windows OS) options for Microsoft* Fortran PowerStation compatibility, the following types of files are possible:

- Formatted Sequential
- Formatted Direct
- Unformatted Sequential
- Unformatted Direct
- Binary Sequential
- Binary Direct

Formatted Sequential Files

A formatted sequential file is a series of formatted records written sequentially and read in the order in which they appear in the file. Records can vary in length and can be empty. They are separated by carriage return (0D) and line feed (0A) characters as shown in the following figure.

Figure 12: Formatted Records in a Formatted Sequential File

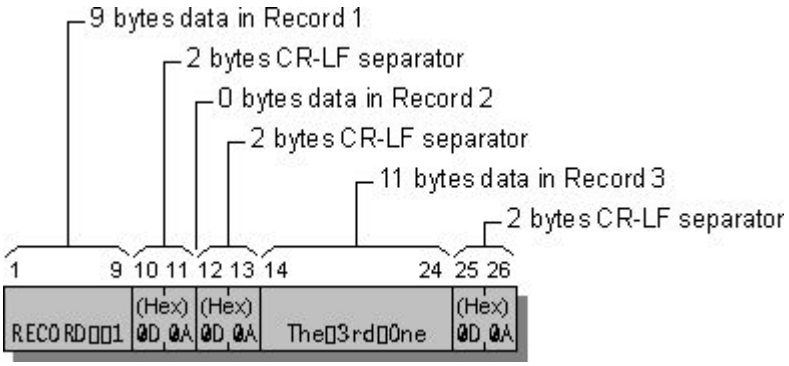


An example of a program writing three records to a formatted sequential file is given below. The resulting file is shown in the following figure.

```
   OPEN (3, FILE='FSEQ')
! FSEQ is a formatted sequential file by default.
  WRITE (3, '(A, I3)') 'RECORD', 1
  WRITE (3, '()')
```

```
WRITE (3, '(A11)') 'The 3rd One'
CLOSE (3)
END
```

Figure 13: Formatted Sequential File



Formatted Direct Files

In a formatted direct file, all of the records are the same length and can be written or read in any order. The record size is specified with the RECL option in an `OPEN` statement and should be equal to or greater than the number of bytes in the longest record.

The carriage return (CR) and line feed (LF) characters are record separators and are not included in the RECL value. Once a direct-access record has been written, you cannot delete it, but you can rewrite it.

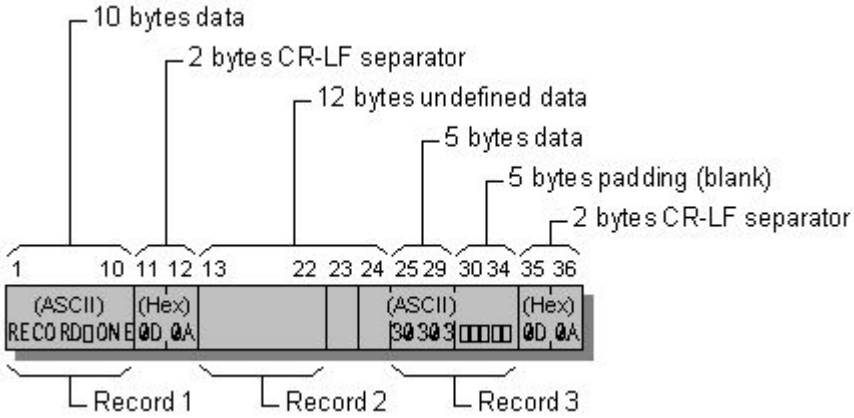
During output to a formatted direct file, if data does not completely fill a record, the compiler pads the remaining portion of the record with blank spaces. The blanks ensure that the file contains only completely filled records, all of the same length. During input, the compiler by default also adds filler bytes (blanks) to the input record if the input list and format require more data than the record contains.

You can override the default blank padding on input by setting PAD='NO' in the `OPEN` statement for the file. If PAD='NO', the input record must contain the amount of data indicated by the input list and format specification. Otherwise, an error occurs. PAD='NO' has no effect on output.

An example of a program writing two records, record one and record three, to a formatted direct file is given below. The result is shown in the following figure.

```
OPEN (3,FILE='FDIR', FORM='FORMATTED', ACCESS='DIRECT',RECL=10)
WRITE (3, '(A10)', REC=1) 'RECORD ONE'
WRITE (3, '(I5)', REC=3) 30303
CLOSE (3)
END
```

Figure 14: Formatted Direct File



Unformatted Sequential Files

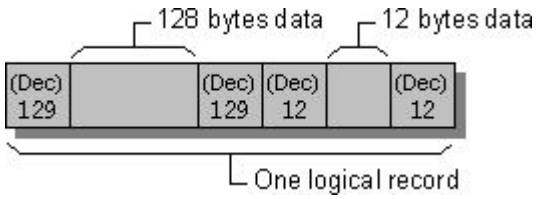
Unformatted sequential files are organized slightly differently on different platforms. This section describes unformatted sequential files created by Intel Fortran when the `-fpscomp` (Linux OS and Mac OS X) or `/fpscomp` (Windows OS) option is specified.

The records in an unformatted sequential file can vary in length. Unformatted sequential files are organized in chunks of 130 bytes or less called *`physical blocks`*. Each physical block consists of the data you send to the file (up to 128 bytes) plus two 1-byte "length bytes" inserted by the compiler. The length bytes indicate where each record begins and ends.

A *`logical record`* refers to an unformatted record that contains one or more physical blocks. (See the following figure.) Logical records can be as big as you want; the compiler will use as many physical blocks as necessary.

When you create a logical record consisting of more than one physical block, the compiler sets the length byte to 129 to indicate that the data in the current physical block continues on into the next physical block. For example, if you write 140 bytes of data, the logical record has the structure shown in the following figure.

Figure 15: Logical Record in Unformatted Sequential File



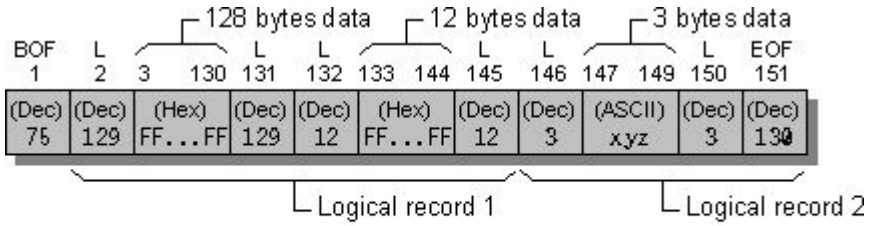
The first and last bytes in an unformatted sequential file are reserved; the first contains a value of 75, and the last holds a value of 130. Fortran uses these bytes for error checking and end-of-file references.

The following program creates the unformatted sequential file shown in the following figure:

```
!   Note: The file is sequential by default
!         -1 is FF FF FF FF hexadecimal.
!
  CHARACTER xyz(3)
  INTEGER(4) idata(35)
  DATA      idata /35 * -1/, xyz /'x', 'y', 'z'/
!
! Open the file and write out a 140-byte record:
! 128 bytes (block) + 12 bytes = 140 for IDATA, then 3 bytes for XYZ.
  OPEN (3, FILE='UFSEQ',FORM='UNFORMATTED')
  WRITE (3) idata
```

```
WRITE (3) xyz
CLOSE (3)
END
```

Figure 16: Unformatted Sequential File



BOF Beginning-of-file byte (75 decimal)
L Physical-block-length byte (0 <= L <= 129)
EOF End-of-file byte (130 decimal)

Unformatted Direct Files

An unformatted direct file is a series of unformatted records. You can write or read the records in any order you choose. All records have the same length, given by the RECL specifier in an `OPEN` statement. No delimiting bytes separate records or otherwise indicate record structure.

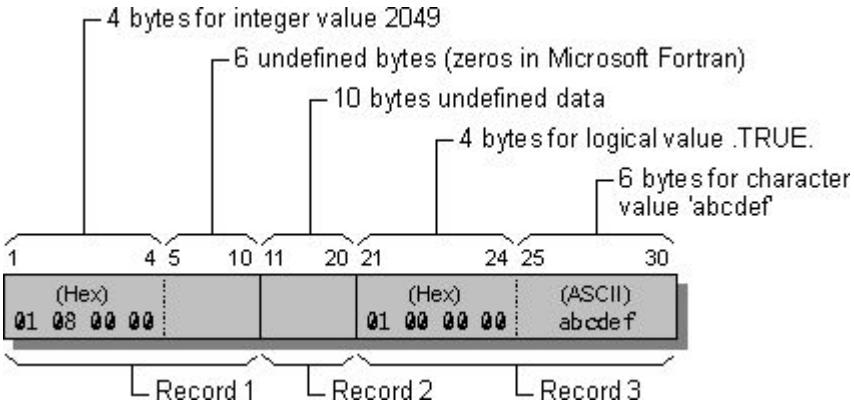
You can write a partial record to an unformatted direct file. Intel Fortran pads these records to the fixed record length with ASCII NULL characters. Unwritten records in the file contain undefined data.

The following program creates the sample unformatted direct file shown in the following figure:

```
 OPEN (3, FILE='UFDIR', RECL=10,&
  & FORM = 'UNFORMATTED', ACCESS = 'DIRECT')
WRITE (3, REC=3) .TRUE., 'abcdef'
```

```
  WRITE (3, REC=1) 2049
  CLOSE (3)
  END
```

Figure 17: Unformatted Direct File



Binary Sequential Files

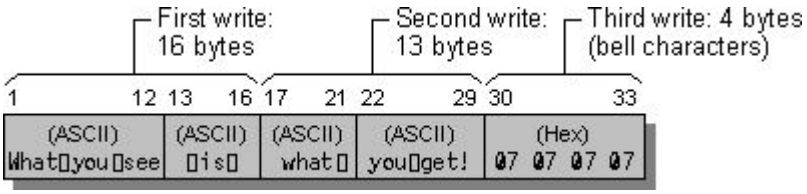
A binary sequential file is a series of values written and read in the same order and stored as binary numbers. No record boundaries exist, and no special bytes indicate file structure. Data is read and written without changes in form or length. For any I/O data item, the sequence of bytes in memory is the sequence of bytes in the file.

The next program creates the binary sequential file shown in the following figure:

```
!  NOTE: 07 is the bell character
!     Sequential is assumed by default.
!
  INTEGER(1) bells(4)
  CHARACTER(4) wys(3)
  CHARACTER(4) cvar
  DATA bells /4*7/
  DATA cvar /' is '/,wys /'What',' you',' see'/
  OPEN (3, FILE='BSEQ',FORM='BINARY')
  WRITE (3) wys, cvar
  WRITE (3) 'what ', 'you get!'
```

```
WRITE (3) bells
CLOSE (3)
END
```

Figure 18: Binary Sequential File



Binary Direct Files

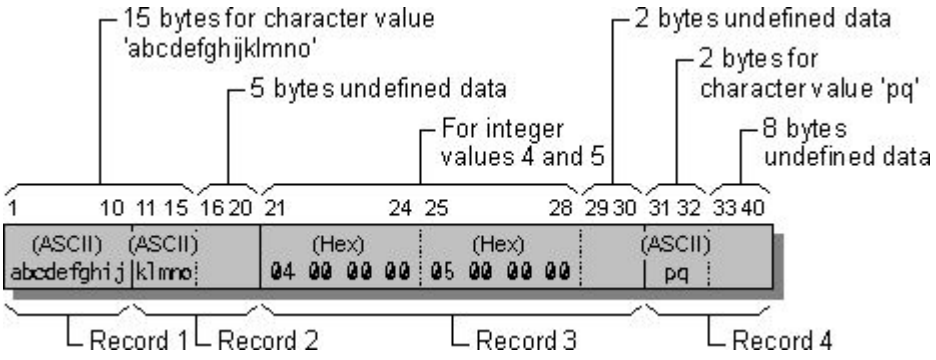
A binary direct file stores records as a series of binary numbers, accessible in any order. Each record in the file has the same length, as specified by the RECL argument to the `OPEN` statement. You can write partial records to binary direct files; any unused portion of the record will contain undefined data.

A single read or write operation can transfer more data than a record contains by continuing the operation into the next records of the file. Performing such an operation on an unformatted direct file would cause an error. Valid I/O operations for unformatted direct files produce identical results when they are performed on binary direct files, provided the operations do not depend on zero padding in partial records.

The following program creates the binary direct file shown in the following figure:

```
 OPEN (3, FILE='BDIR',RECL=10,FORM='BINARY',ACCESS='DIRECT')
WRITE (3, REC=1) 'abcdefghijklmno'
WRITE (3) 4,5
WRITE (3, REC=4) 'pq'
CLOSE (3)  END
```

Figure 19: Binary Direct File



Using Asynchronous I/O

For external files, you can specify that I/O should be asynchronous. By doing this, you allow other statements to execute while an I/O statement is executing.

NOTE. In order to execute a program that uses asynchronous I/O on Linux* OS or Mac OS* X systems, you must explicitly include one of the following compiler command line options when you compile and link your program:

- `-threads`
- `-reentrancy threaded`
- `-openmp`

On Windows* OS systems, no extra options are needed to execute a program that uses asynchronous I/O.

Using the ASYNCHRONOUS Specifier

Asynchronous I/O is supported for all READ and WRITE operations to external files. However, if you specify asynchronous I/O, you cannot use variable format expressions in formatted I/O operations.

To allow asynchronous I/O for a file, first specify ASYNCHRONOUS='YES' in its OPEN statement, then do the same for each READ or WRITE statement that you want to execute in this manner.

Execution of an asynchronous I/O statement initiates a "pending" I/O operation, which can be terminated in the following ways:

- by an explicit WAIT (initno) statement, which performs a wait operation for the specified pending asynchronous data transfer operation
- by a CLOSE statement for the file
- by a file-positioning statement such as REWIND or BACKSPACE
- by an INQUIRE statement for the file

Use the WAIT statement to ensure that the objects used in the asynchronous data transfer statements are not prematurely deallocated. (This is especially important for local stack objects and allocatable objects which may be deallocated before completion of the pending operation.) If you do not specify the wait operation, the program may terminate with an Access violation error. The following example shows use of the WAIT statement:

```
module mod
   real, allocatable :: X(:)
end module mod
subroutine sbr()
use mod
integer :: Y(500)
   !X and Y initialization
   allocate (X(500))
   call foo1(X, Y)
   !asynchronous writing
   open(1, asynchronous='yes')
   write(1, asynchronous='yes') X, Y
   !some computation
   call foo2()
   !wait operation
   wait(1)
   !X deallocation
   deallocate(X)
   !stack allocated object Y will be deallocated when the routine returns
end subroutine sbr
```

You can use the INQUIRE statement with the keyword of ASYNCHRONOUS (ASYNCHRONOUS=specifier) to determine whether asynchronous I/O is allowed. If it is allowed, a value of YES is returned.

Additionally, you can use the INQUIRE statement with the keyword of PENDING (PENDING= specifier) to determine whether previously pending asynchronous data transfers are complete.

If an ID= specifier appears and the specified data transfer operation is complete, the variable specified by PENDING is assigned the value False and the INQUIRE statement performs a wait operation for the specified data transfer.

If the ID= specifier is omitted and all previously pending data transfer operations for the specified unit are complete, the variable specified by PENDING is assigned the value False and the INQUIRE statement performs wait operations for all previously pending data transfers for the specified unit.

Otherwise, the variable specified by PENDING is assigned the value True and no wait operations are performed. Previously pending data transfers remain pending.

Using the ASYNCHRONOUS Attribute

A data attribute called ASYNCHRONOUS specifies that a variable may be subject to asynchronous input/output. Assigning this attribute to a variable allows certain optimizations to occur.

For more information, see the following topics in the Language Reference:

Asynchronous Specifier

Open: ASYNCHRONOUS Specifier

INQUIRE: ASYNCHRONOUS Specifier

ASYNCHRONOUS Statement and Attributes

Structuring Your Program 12

Structuring Your Program Overview

There are several ways to organize your projects and the applications that you build with Intel® Fortran. This section introduces several of these options and offers suggestions for when you might want to use them.

See Also

- Structuring Your Program
- Creating Fortran Executables
- Using Module (.mod) Files
- Using Include Files
- Advantages of Internal Procedures
- Storing Object Code in Static Libraries
- Storing Routines in Shareable Libraries

Creating Fortran Executables

The simplest way to build an application is to compile all of your Intel® Fortran source files and then link the resulting object files into a single executable file. You can build single-file executables using the ifort command from the command line. For Windows* OS, you can also use the visual development environment.

The executable file you build with this method contains all of the code needed to execute the program, including the run-time library. Because the program resides in a single file, it is easy to copy or install. However, the project contains all of the source and object files for the routines that you used to build the application. If you need to use some of these routines in other projects, you must link all of them again.

Exceptions to this are as follows:

- If you are using shared libraries, all code will not be contained in the executable file.
- On Mac OS* X, the object files contain debug information and would need to be copied along with the executable.

Using Module (.mod) Files

One way to reduce potential confusion when you use the same source code in several projects is to organize the routines into modules. A module (.mod file) is a type of program unit that contains specifications of such entities as data objects, parameters, structures, procedures, and operators. These precompiled specifications and definitions can be used by one or more program units. Partial or complete access to the module entities is provided by the a program's USE statement. Typical applications of modules are the specification of global data or the specification of a derived type and its associated operations.

Modules are excellent ways to organize programs. You can set up separate modules for:

- Commonly used routines
- Data definitions specific to certain operating systems
- System-dependent language extensions

Some programs require modules located in multiple directories. You can use the `-I` (Linux* OS and Mac OS* X) or `/I` compiler (Windows* OS) option when you compile the program to specify the location of the `.mod` files that should be included in the program.

You can use the `-module` path (Linux OS and Mac OS X) or `/module:path` (Windows OS) option to specify the directory in which to create the module files. If you don't use this option, module files are created in the current directory.

Directories are searched for `.mod` files in this order:

1. Directory of the source file that contains the USE statement
2. Directories specified by the `-module path` (Linux OS and Mac OS X) or `/module:path` (Windows OS) option
3. Current working directory
4. Directories specified by the `-Idir` (Linux OS and Mac OS X) or `/include` (Windows OS) option
5. Directories specified with the `FPATH` (Linux OS and Mac OS X) or `INCLUDE` (Windows OS) environment variable
6. Standard system directories

You need to make sure that the module files are created before they are referenced by another program or subprogram.

Compiling Programs with Modules

If a file being compiled has one or more modules defined in it, the compiler generates one or more `.mod` files.

For example, a file `a.f90` contains modules defined as follows:

```
module test
integer:: a
contains
  subroutine f()
  end subroutine
end module test
module payroll
.
.
.
end module payroll
```

This compiler command:

```
ifort -ca.f90
```

generates the following files:

- `test.mod`
- `payroll.mod`
- `a.o` (Linux OS and Mac OS X) or `a.obj` (Windows OS)

The `.mod` files contain the necessary information regarding the modules that have been defined in the program `a.f90`.

The following example uses the program program mod_def.f90 which contains a module defined as follows:

```
file: mod_def.f90
module definedmod
.
.
.
end module
```

Compile the program as follows:

```
ifort -c mod_def.f90
```

This produces the object files `mod_def.o` (Linux OS and Mac OS X) or `mod_def.obj` (Windows OS) and also the .mod file `definedmod.mod`, all in the current directory.

If you need to use the .mod file in another directory, do the following:

```
file: use_mod_def.f90
program usemod
use definedmod
.
.
.
end program
```

To compile the above program, use the -I (Linux OS) or /I (Windows OS) option to specify the path to search and locate the definedmod.mod file.

Using Include Files

Include files are brought into a program with the #include preprocessor directive or a Fortran INCLUDE statement.

Directories are searched for include files in this order:

1. Directory of the source file that contains the include
2. Current working directory
3. Directories specified by the -I (Linux OS and Mac OS X) or /I (Windows OS) option
4. Directory specified by the -isystem option (Linux OS and Mac OS X systems only)
5. Directories specified with the FPATH (Linux OS and Mac OS X) or INCLUDE (Windows OS) environment variable
6. Standard system directories

The locations of directories to be searched are known as the include file path. More than one directory can be specified in the include file path.

Specifying and Removing an Include File Path

You can use the -I (Linux OS and Mac OS X) or /I (Windows OS) option to indicate the location of include files (and also module files).

To prevent the compiler from searching the default path specified by the FPATH or the INCLUDE environment variable, use the -X or /noinclude option.

You can specify these options in the configuration file, ifort.cfg, or on the command line.

For example, to direct the compiler to search a specified path instead of the default path, use the following command line:

```
ifort -X -I/alt/include newmain.f (Linux OS and Mac OS X)
ifort /noinclude /IC:/Project2/include newmain.f (Windows OS)
```

For more information, see the following topic:

- I compiler option

Advantages of Internal Procedures

Functions or subroutines that are used in only one program can be organized as internal procedures, following the `CONTAINS` statement of a program or module.

Internal procedures have the advantage of host association, that is, variables declared and used in the main program are also available to any internal procedure it may contain. For more information on procedures and host association, see Program Units and Procedures.

Internal procedures, like modules, provide a means of encapsulation. Where modules can be used to store routines commonly used by many programs, internal procedures separate functions and subroutines whose use is limited or temporary.

Storing Object Code in Static Libraries

Another way to organize source code used by several projects is to build a static library (for Windows* OS, `.lib` and for Linux* OS and Mac OS* X, `.a`) containing the object files for the reused procedures. You can create a static library by doing the following:

- From the Microsoft Visual Studio* integrated development environment (IDE), create and build a Fortran Static Library project type.
- From the command line, use the `ar` command (on Linux OS and Mac OS X) or the `LIB` command (on Windows OS).

After you have created a static library, you can use it as input to other types of Intel Fortran projects.

Storing Routines in Shareable Libraries

You can organize the code in your application by storing the executable code for certain routines in a shareable library (`.dll` for Windows* OS, `.so` for Linux* OS, `.dylib` for Mac OS* X). You can then build your applications so that they call these routines from the shareable library.

When routines in a shareable library are called, the routines are loaded into memory at run-time as they are needed. This is most useful when several applications use a common group of routines. By storing these common routines in a shareable library, you reduce the size of each application that calls the library. In addition, you can update the routines in the library without having to rebuild any of the applications that call the library.

Programming with Mixed Languages

13

Programming with Mixed Languages Overview

Mixed-language programming is the process of building programs in which the source code is written in two or more languages. It allows you to:

- Call existing code that is written in another language
- Use procedures that may be difficult to implement in a particular language
- Gain advantages in processing speeds

Mixed-language programming is possible between Intel® Fortran and other languages. Although other languages (such as assembly language) are discussed, the primary focus of this section is programming using Intel Fortran and C/C++ . Mixed language programming between these two languages is relatively straightforwardbecause each language implements functions, subroutines, and procedures in approximately the same way.

Calling Subprograms from the Main Program

Calls from the Main Program

The Intel® Fortran main program can call Intel Fortran subprograms, including subprograms in static and shared libraries.

For mixed-language applications, the Intel Fortran main program can call subprograms written in C/C++ if the appropriate calling conventions are used (see Calling C Procedures from a Fortran program).

Intel Fortran subprograms can be called by C/C++ main programs. If the main program is C/C++, you need to use the `-nofor_main` compiler option to indicate this.

Calls to the Subprogram

You can use subprograms in static libraries if the main program is written in Intel Fortran or C/C++.

You can use subprograms in shared libraries in mixed-language applications if the main program is written in Intel Fortran or C/C++.

Summary of Mixed-Language Issues

Mixed-language programming involves a call from a routine written in one language to a function, procedure, or subroutine written in another language. For example, a Fortran main program may need to execute a specific task that you want to program separately in an assembly-language procedure, or you may need to call an existing shared library or system procedure.

Mixed-language programming is possible with Intel® Fortran, Visual C/C++*, and Intel® C++, because each language implements functions, subroutines, and procedures in approximately the same way.

Intel Fortran includes several Fortran 2003 features that provide interoperability with C. An entity is considered interoperable if equivalent declarations can be made for it in both languages. Interoperability is provided for variables, derived types, and procedures.

The following features are supported:

- BIND attribute and statement, which specifies that an object is interoperable with C and has external linkage.
- language binding in FUNCTION and SUBROUTINE statements
- language binding in derived-type statements

For more information, see Interoperability with C.

Programming with Fortran and C/C++ Considerations

A summary of major Fortran and C/C++ mixed-language issues follows:

- Fortran and C implement functions and routines differently. For example, a C main program could call an external void function, which is actually implemented as a Fortran subroutine:

  Table 32: Language Equivalents for Calls to Routines

Language	Call with Return Value	Call with No Return Value
Fortran	FUNCTION	SUBROUTINE
C and C++	function	(void) function

- Generally, Fortran/C programs are mixed to allow one to use existing code written in the other language. Either Fortran or C can call the other, so the main routine can be in either language. On Linux OS and Mac OS X systems, if Fortran is not the main routine, the `-nofor-main` compiler option must be specified on the command line.

- To use the same Microsoft* visual development environment for multiple languages, you must have the same version of the visual development environment for your languages.
- Fortran adds an underscore to external names; C does not.
- Fortran changes the case of external names to lowercase; C leaves them in their original case.
- Fortran passes numeric data by reference; C passes by value.

NOTE. You can override some default Fortran behavior by using ATTRIBUTES and ALIAS. ATTRIBUTES C causes Fortran to act like C in external names and the passing of numeric data. ALIAS causes Fortran to use external names in their original case.

- Fortran subroutines are equivalent to C void routines.
- Fortran requires that the length of strings be passed; C is able to calculate the length based on the presence of a trailing null. Therefore, if Fortran is passing a string to a C routine, that string needs to be terminated by a null; for example:

```
"mystring"c or  StringVar // CHAR(0)
```

- For the following data types, Fortran adds a hidden first argument to contain function return values: COMPLEX, REAL*16, CHARACTER, and derived types.
- On Linux* systems, the `-fexceptions` option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines.

For more information on mixed language programming using Intel Fortran and C, see the following:

- Compiling and Linking Intel Fortran/C Programs
- Calling C Procedures from an Intel Fortran Program

Programming with Fortran and Assembly-Language Considerations

A summary of Fortran/assembly language issues follows:

- Assembly-language routines can be small and can execute quickly because they do not require initialization as do high-level languages like Fortran and C.

- Assembly-language routines allow access to hardware instructions unavailable to the high-level language user. In a Fortran/assembly-language program, compiling the main routine in Fortran gives the assembly code access to Fortran high-level procedures and library functions, yet allows freedom to tune the assembly-language routines for maximum speed and efficiency. The main program can also be an assembly-language program.

Other Mixed-Language Programming Considerations

There are other important differences in languages; for instance, argument passing, naming conventions, and other interface issues must be thoughtfully and consistently reconciled between any two languages to prevent program failure and indeterminate results. However, the advantages of mixed-language programming often make the extra effort worthwhile. The remainder of this section provides an explanation of the techniques you can use to reconcile differences between Fortran and other languages.

Adjusting calling conventions, adjusting naming conventions and writing interface procedures are discussed in the following topics:

- Adjusting Calling Conventions in Mixed-Language Programming
- Adjusting Naming Conventions in Mixed-Language Programming
- Prototyping a Procedure in Fortran

After establishing a consistent interface between mixed-language procedures, you then need to reconcile any differences in the treatment of individual data types (strings, arrays, and so on). This is discussed in Exchanging and Accessing Data in Mixed-Language Programming. You also need to be concerned with data types, because each language handles them differently. This is discussed in Handling Data Types in Mixed-Language Programming.

NOTE. This section uses the term "routine" in a generic way, to refer to functions, subroutines, and procedures from different languages.

Adjusting Calling Conventions in Mixed-Language Programming

Adjusting Calling Conventions in Mixed-Language Programming Overview

The calling convention determines how a program makes a call to a routine, how the arguments are passed, and how the routines are named.

A calling convention includes:

- Stack considerations
  - Does a routine receive a varying or fixed number of arguments?
  - Which routine clears the stack after a call?
- Naming conventions
  - Is lowercase or uppercase significant or not significant?
  - Are external names altered?
- Argument passing protocol
  - Are arguments passed by value or by reference?
  - What are the equivalent data types and data structures among languages?

In a single-language program, calling conventions are nearly always correct, because there is one default for all routines and because header files or Fortran module files with interface blocks enforce consistency between the caller and the called routine.

In a mixed-language program, different languages cannot share the same header files. If you link Fortran and C routines that use different calling conventions, the error is not apparent until the bad call is made at run time. During execution, the bad call causes indeterminate results and/or a fatal error. The error, caused by memory or stack corruption due to calling errors, often occurs in a seemingly arbitrary place in the program.

The discussion of calling conventions between languages applies only to external procedures. You cannot call internal procedures from outside the program unit that contains them.

A calling convention affects programming in a number of ways:

1. The caller routine uses a calling convention to determine the order in which to pass arguments to another routine; the called routine uses a calling convention to determine the order in which to receive the arguments passed to it. In Fortran, you can specify these conventions in a mixed-language interface with the `INTERFACE` statement or in a data or function declaration. C/C++ and Fortran both pass arguments in order from left to right.
2. The caller routine and the called routine use a calling convention to select the option of passing a variable number of arguments.
3. The caller routine and the called routine use a calling convention to pass arguments by value (values passed) or by reference (addresses passed). Individual Fortran arguments can also be designated with `ATTRIBUTES` option VALUE or REFERENCE.

4. The caller routine and the called routine use a calling convention to establish naming conventions for procedure names. You can establish any procedure name you want, regardless of its Fortran name, with the ALIAS directive (or ATTRIBUTES option ALIAS). This is useful because C is case sensitive, while Fortran is not.

ATTRIBUTES Properties and Calling Conventions

The ATTRIBUTES properties (also known as options) C, STDCALL (Windows* OS only), REFERENCE, VALUE, and VARYING affect the calling convention of routines. You can specify:

- The C, STDCALL, REFERENCE, and VARYING properties for an entire routine.
- The VALUE and REFERENCE properties for individual arguments.

By default, Fortran passes all data by reference (except the hidden length argument of strings, which is passed by value). If the C (or, for Windows OS, STDCALL) option is used, the default changes to passing almost all data except arrays by value. However, in addition to the calling-convention options C and STDCALL, you can specify argument options, VALUE and REFERENCE, to pass arguments by value or by reference, regardless of the calling convention option. Arrays can only be passed by reference.

Different Fortran calling conventions can be specified by declaring the Fortran procedure to have certain attributes.

It is advisable to use the DECORATE option in combination with the ALIAS option to ensure appropriate name decoration regardless of operating system or architecture. The DECORATE option indicates that the external name specified in ALIAS should have the correct prefix and postfix decorations for the calling mechanism in effect.

Naming conventions are as follows:

- leading (prefix) underscore for Windows operating systems based on IA-32 architecture; no underscores for Windows operating systems based on Intel® 64 architecture and Windows systems based on IA-64 architecture.
- trailing (postfix) underscore for all Linux operating systems
- leading and trailing underscores for all Mac OS* X operating systems

For example:

```
   INTERFACE
      SUBROUTINE MY_SUB (I)
          !DEC$ ATTRIBUTES C, DECORATE, ALIAS:'My_Sub'
 :: MY_SUB
          INTEGER I
      END SUBROUTINE MY_SUB
   END INTERFACE
```

This code declares a subroutine named `MY_SUB` with the C property. The external name will be appropriately decorated for the operating system and platform.

The following table summarizes the effect of the most common Fortran calling-convention directives.

Table 33: Calling Conventions for ATTRIBUTES Options

Argument	Default	C	C, REFERENCE	STDCALL (Windows OS IA-32 architecture)	STDCALL, REFERENCE (Windows OS IA-32 architecture)
Scalar	Reference	Value	Reference	Value	Reference
Scalar [value]	Value	Value	Value	Value	Value
Scalar [reference]	Reference	Reference	Reference	Reference	Reference
String	Reference, either Len:End or Len:Mixed	String(1:1)	Reference, either Len:End or Len:Mixed	String(1:1)	String(1:1)
String [value]	Error	String(1:1)	String(1:1)	String(1:1)	String(1:1)
String [reference]	Reference, either No Len or Len:Mixed	Reference, No Len	Reference, No Len	Reference, No Len	Reference, No Len
Array	Reference	Reference	Reference	Reference	Reference
Array [value]	Error	Error	Error	Error	Error
Array [reference]	Reference	Reference	Reference	Reference	Reference
Derived Type	Reference	Value, size dependent	Reference	Value, size dependent	Reference

Argument	Default	C	C, REFERENCE	STDCALL (Windows OS IA-32 architecture)	STDCALL, REFERENCE (Windows OS IA-32 architecture)
Derived Type [value]	Value, size dependent	Value, size dependent	Value, size dependent	Value, size dependent	Value, size dependent
Derived Type [reference]	Reference	Reference	Reference	Reference	Reference
F90 Pointer	Descriptor	Descriptor	Descriptor	Descriptor	Descriptor
F90 Pointer [value]	Error	Error	Error	Error	Error
F90 Pointer [reference]	Descriptor	Descriptor	Descriptor	Descriptor	Descriptor
Naming Conventions					
Prefix	_ (Windows operating systems using IA-32 architecture, Mac OS X operating systems) *none* for all others	_ (Windows operating systems using IA-32 architecture, Mac OS X operating systems) *none* for all others	_ (Windows operating systems using IA-32 architecture, Mac OS X operating systems) *none* for all others	_	_
Suffix	none (Windows OS) _ (Linux OS, Mac OS X)	*none*	*none*	@*n*	@*n*

Argument	Default	C	C, REFERENCE	STDCALL (Windows OS IA-32 architecture)	STDCALL, REFERENCE (Windows OS IA-32 architecture)
Case	Upper Case	Lower Case	Lower Case	Lower Case	Lower Case
Stack Cleanup	Caller	Caller	Caller	Callee	Callee

The terms in the above table mean the following:

[value] Argument assigned the VALUE attribute.

[reference] Argument assigned the REFERENCE attribute.

Value The argument value is pushed on the stack. All values are padded to the next 4-byte boundary.

Reference On systems using IA-32 architecture, the 4-byte argument address is pushed on the stack.

On systems using Intel® 64 and IA-64 architectures, the 8-byte argument address is pushed on the stack.

Len:End or Len:Mixed For certain string arguments:

- Len:End applies when -nomixed-str-len-arg (Linux OS and Mac OS X) or /iface:nomixed_str_len_arg (Windows) is set. The length of the string is pushed (by value) on the stack after all of the other arguments. This is the default.
- Len:Mixed applies when -mixed-str-len-arg (Linux OS and Mac OS X) or /iface:mixed_str_len_arg (Windows) is set. The length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.

No Len or Len:Mixed For certain string arguments:

- No Len applies when nomixed-str-len-arg (Linux OS and Mac OS X) or /iface:nomixed_str_len_arg (Windows) is set. The length of the string is not available to the called procedure. This is the default.

	• Len:Mixed applies when mixed-str-len-arg (Linux OS and Mac OS X) or /iface:mixed_str_len_arg (Windows) is set. The length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.
No Len	For string arguments, the length of the string is not available to the called procedure.
String(1:1)	For string arguments, the first character is converted to INTEGER(4) as in ICHAR(string(1:1)) and pushed on the stack by value.
Error	Produces a compiler error.
Descriptor	On systems using IA-32 architecture, the 4-byte address of the array descriptor. On systems using Intel® 64 architecture and systems using IA-64 architecture, the 8-byte address of the array descriptor.
@*n*	On systems using IA-32 architecture, the at sign (@) followed by the number of bytes (in decimal) required for the argument list.
Size dependent	On systems using IA-32 architecture, derived-type arguments specified by value are passed as follows: • Arguments from 1 to 4 bytes are passed by value. • Arguments from 5 to 8 bytes are passed by value in two registers (two arguments). • Arguments more than 8 bytes provide value semantics by passing a temporary storage address by reference.
Upper Case	Procedure name in all uppercase.
Lower Case	Procedure name in all lowercase.
Callee	The procedure being called is responsible for removing arguments from the stack before returning to the caller.
Caller	The procedure doing the call is responsible for removing arguments from the stack after the call is over.

The following table shows which Fortran ATTRIBUTES options match other language calling conventions.

Table 35: Matching Calling Conventions

Other Language Calling Convention	Matching ATTRIBUTES Option
C/C++ cdecl (default)	C
C/C++ __stdcall (Windows OS only)	STDCALL
MASM C (in PROTO and PROC declarations) (Windows OS only)	C
MASM STDCALL (in PROTO and PROC declarations) (Windows OS only)	STDCALL
Assembly (Linux OS only)	C

The ALIAS option can be used with any other Fortran calling-convention option to preserve mixed-case names. You can also use the DECORATE option in combination with the ALIAS option to specify that the external name specified in ALIAS should have the correct prefix and postfix decorations for the calling mechanism in effect.

For Windows operating systems, the compiler option `/iface` also establishes some default argument passing conventions. The `/iface` option has the following choices:

Option	How are arguments passed?	Append `@n` to names on systems using IA-32 architecture?	Who cleans up stack?	Varargs support?
/iface:cref	By reference	No	Caller	Yes
/iface:stdref	By reference	Yes	Callee	No
/iface:default	By reference	No	Caller	Yes
/iface:c	By value	No	Caller	Yes
/iface:stdcall	By value	Yes	Callee	No
/iface:cvf	By reference	Yes	Callee	No

Adjusting Naming Conventions in Mixed-Language Programming

Adjusting Naming Conventions in Mixed-Language Programming Overview

The ATTRIBUTES options C and, for Windows* OS, STDCALL, determine naming conventions as well as calling conventions.

Calling conventions specify how arguments are moved and stored; naming conventions specify how symbol names are altered when placed in an .OBJ file. Names are an issue for external data symbols shared among parts of the same program as well as among external routines. Symbol names (such as the name of a subroutine) identify a memory location that must be consistent among all calling routines.

Parameter names (names given in a procedure definition to variables that are passed to it) are never affected.

Names are altered because of case sensitivity (in C and MASM), lack of case sensitivity (in Fortran), name decoration (in C++), or other issues. If naming conventions are not reconciled, the program cannot successfully link and you will receive an "unresolved external" error.

C/C++ Naming Conventions

C and C++ preserve case sensitivity in their symbol tables while Fortran by default does not; this is a difference that requires attention. Fortunately, you can use the Fortran directive `ATTRIBUTES` ALIAS option to resolve discrepancies between names, to preserve mixed-case names, or to override the automatic case conversion of names by Fortran.

C++ uses the same calling convention and argument-passing techniques as C, but naming conventions differ because of C++ decoration of external symbols. When the C++ code resides in a `.cpp` file (created when you select C/C++ file from the integrated development environment), C++ name decoration semantics are applied to external names, often resulting in linker errors. The extern "C" syntax makes it possible for a C++ module to share data and routines with other languages by causing C++ to drop name decoration.

The following example declares `prn` as an external function using the C naming convention. This declaration appears in C++ source code:

```
extern "C" { void prn(); }
```

To call functions written in Fortran, declare the function as you would in C and use a "C" linkage specification. For example, to call the Fortran function FACT from C++, declare it as follows:

```
extern "C" { int fact( int* n ); }
```

The extern "C" syntax can be used to adjust a call from C++ to other languages, or to change the naming convention of C++ routines called from other languages. However, extern "C" can only be used from within C++. If the C++ code does not use extern "C" and cannot be changed,

you can call C++ routines only by determining the name decoration and generating it from the other language. Such an approach should only be used as a last resort, because the decoration scheme is not guaranteed to remain the same between versions.

Use of extern "C" has some restrictions:

- You cannot declare a member function with extern "C".
- You can specify extern "C" for only one instance of an overloaded function; all other instances of an overloaded function have C++ linkage.

Procedure Names for Fortran, C, C++, and MASM

The following table summarizes how Fortran, C/C++ and, for Windows, MASM handle procedure names. Note that for MASM, the table does not apply if the CASEMAP: ALL option is used.

Table 37: Naming Conventions in Fortran, C, Visual C++, and MASM

Language	Attributes	Name Translated As	Case of Name in .OBJ File
Fortran	*c***DEC$ ATTRIBUTES** C	*name* (Linux* OS) *_name* (Windows* OS) *_name* (Mac OS* X)	All lowercase
Fortran (Windows OS)	*c***DEC$ ATTRIBUTES** STDCALL	*_name*@*n*	All lowercase
Fortran	default	*name_* (Linux OS) *_name* (Windows OS) *_name_* (Mac OS X)	All uppercase
C	cdecl (default)	*name* (Linux OS) *_name* (Windows OS) *_name* (Mac OS X)	Mixed case preserved
C (Windows OS only)	__stdcall	*_name*@*n*	Mixed case preserved

Language	Attributes	Name Translated As	Case of Name in .OBJ File
C++	Default	*name*@@*decoration* (Linux OS) *_name*@@*decoration* (Windows OS) __decoration*name*decoration (Mac OS X)	Mixed case preserved
Linux OS, Mac OS X Assembly	Default	*name* (Linux OS) *_name* (Mac OS X)	Mixed case preserved
MASM (Windows OS)	C (in PROTO and PROC declarations)	*_name*	Mixed case preserved
MASM (Windows OS)	STDCALL (in PROTO and PROC declarations)	*_name*@*n*	Mixed case preserved

In the preceding table:

- The leading underscore (such as *_name*) is used on Windows operating systems based on IA-32 architecture only.
- @*n* represents the stack space, in decimal notation, occupied by parameters on Windows operating systems based on IA-32 architecture only.

For example, assume a function is declared in C as:

```
extern int __stdcall Sum_Up( int a, int b, int c );
```

Each integer occupies 4 bytes, so the symbol name placed in the .OBJ file on systems based on IA-32 architecture is:

```
_Sum_Up@12
```

On systems based on Intel® 64 architecture and those based on IA-64 architecture, the symbol name placed in the .OBJ file is:

```
Sum_Up
```

Reconciling the Case of Names

The following summarizes how to reconcile names between languages:

- All-Uppercase Names (default on Windows OS)

  If you call a Fortran routine that uses Fortran defaults and cannot recompile the Fortran code, then in C,you must use an all-uppercase name to make the call. In MASM you must either use an all-uppercase name or set the OPTION CASEMAP directive to ALL, which translates all identifiers to uppercase. Use of the __stdcall convention in C code or STDCALL in MASM PROTO and PROC declarations is not enough, because __stdcall and STDCALL always preserve case in these languages. Fortran generates all-uppercase names by default and the C or MASM code must match it.

  For example, these prototypes establish the Fortran function FFARCTAN(angle) where the argument angle has the `ATTRIBUTES` VALUE property:

  - In C:

    ```
    extern float FFARCTAN( float angle );
    ```

  - In MASM:

    ```
    .MODEL FLAT
    FFARCTAN PROTO, angle: REAL4
    ...
    FFARCTAN PROC, angle: REAL4
    ```

- All-Lowercase Names (default on Linux OS and Mac OS X)

  If the name of the routine appears as all lowercase in C or assembly, then naming conventions are automatically correct. Any case may be used in the Fortran source code, including mixed case since the name is changed to all lowercase.

  In Linux OS/Mac OS X Assembly, the following establishes the Fortran function `ffarctan`:

  ```
  #--Begin ffarctan_
  .globl ffarctan_
  ```

- Mixed-Case Names

  If the name of a routine appears as mixed-case in C or MASM and you need to preserve the case, use the Fortran `ATTRIBUTES` ALIAS option.

  To use the ALIAS option, place the name in quotation marks exactly as it is to appear in the object file.

  The following is an example for referring to the C function My_Proc:

  ```
  !DEC$ ATTRIBUTES DECORATE,ALIAS:'My_Proc'
   :: My_Proc
  ```

  This example uses DECORATE to automatically reconcile the external name for the target platform.

Fortran Module Names and ATTRIBUTES

Fortran module entities (data and procedures) have external names that differ from other external entities. Module names use the convention:

```
modulename_mp_entity_(Linux OS and Mac OS X)
_MODULENAME_mp_ENTITY [ @stacksize ] (Windows OS)
```

modulename is the name of the module. For Windows* operating systems, the name is uppercase by default.

`entity` is the name of the module procedure or module data contained within *MODULENAME*. For Windows* operating systems, *ENTITY* is uppercase by default.

*_mp_* is the separator between the module and entity names and is always lowercase.

For example:

```
    MODULE mymod
      INTEGER a
   CONTAINS
      SUBROUTINE b (j)
         INTEGER j
      END SUBROUTINE
   END MODULE
```

This results in the following symbols being defined in the compiled object file on Linux operating systems (On Mac OS X operating systems, the symbols would begin with an underscore)::

```
mymod_mp_a_
mymod_mp_b_
```

The following symbols are defined in the compiled object file on Windows operating systems based on IA-32 architecture:

```
_MYMOD_mp_A
_MYMOD_mp_B
```

Compiler options can affect the naming of module data and procedures.

NOTE. Except for ALIAS, `ATTRIBUTES` options do not affect the module name.

The following table shows how each ATTRIBUTES option affects the subroutine in the previous example module.

Table 38: Effect of ATTRIBUTES options on Fortran Module Names

ATTRIBUTES Option Given to Routine 'b'	Procedure Name in .OBJ file on Systems Using IA-32 Architecture	Procedure Name in .OBJ file on Systems Using Intel® 64 Architecture and IA-64 Architecture
None	`mymod_mp_b_` (Linux OS) `_mymod_mp_b_` (Mac OS X) `_MYMOD_mp_B` (Windows OS)	`mymod_mp_b_` (Linux OS) `_mymod_mp_b_` (Mac OS X) `MYMOD_mp_B` (Windows OS)
C	`mymod_mp_b_` (Linux OS) `_mymod_mp_b_` (Mac OS X) `MYMOD_mp_b` (Windows OS)	`mymod_mp_b` (Linux OS) `_mymod_mp_b` (Mac OS X) `MYMOD_mp_b` (Windows OS)
STDCALL (Windows OS only)	`_MYMOD_mp_b@4`	`MYMOD_mp_b`
ALIAS	Overrides all others, name as given in the alias	Overrides all others, name as given in the alias
VARYING	No effect on name	No effect on name

You can write code to call Fortran modules or access module data from other languages. As with other naming and calling conventions, the module name must match between the two languages. Generally, this means using the C or STDCALL convention in Fortran, and if defining a module in another language, using the ALIAS option to match the name within Fortran. For examples, see Using Modules in Mixed-Language Programming.

Prototyping a Procedure in Fortran

You define a prototype (interface block) in your Fortran source code to tell the Fortran compiler which language conventions you want to use for an external reference. The interface block is introduced by the `INTERFACE` statement. See Program Units and Procedures for a more detailed description of the `INTERFACE` statement.

The general form for the INTERFACE statement is:

```
INTERFACE
routine statement
[routine ATTRIBUTE options]
[argument ATTRIBUTE options]
formal argument declarations
END routine name
END INTERFACE
```

The *routine statement* defines either a FUNCTION or a SUBROUTINE, where the choice depends on whether a value is returned or not, respectively. The optional *routine* ATTRIBUTE options (such as C, and, for Windows, STDCALL) determine the calling, naming, and argument-passing conventions for the routine in the prototype statement. The optional *argument* ATTRIBUTE options (such as VALUE and REFERENCE) are properties attached to individual arguments. The *formal argument declarations* are Fortran data type declarations. Note that the same INTERFACE block can specify more than one procedure.

For example, suppose you are calling a C function that has the following prototype:

```
extern void My_Proc (int i);
```

The Fortran call to this function should be declared with the following INTERFACE block:

```
INTERFACE
  SUBROUTINE my_Proc (I)
   !DEC$ ATTRIBUTES C, DECORATE, ALIAS:'My_Proc' :: my_Proc
   INTEGER I
  END SUBROUTINE my_Proc
END INTERFACE
```

Note that, except in the ALIAS string, the case of My_Proc in the Fortran program does not matter.

Exchanging and Accessing Data in Mixed-Language Programming

Exchanging and Accessing Data in Mixed-Language Programming

You can use several approaches to sharing data between mixed-language routines, which can be used within the individual languages as well.

Generally, if you have a large number of parameters to work with or you have a large variety of parameter types, you should consider using modules or external data declarations. This is true when using any given language, and to an even greater extent when using mixed languages.

See Also

- Exchanging and Accessing Data in Mixed-Language Programming

- Passing Arguments in Mixed-Language Programming
- Using Modules in Mixed-Language Programming
- Using Common External Data in Mixed-Language Programming

Passing Arguments in Mixed-Language Programming

You can pass data between Fortran and C, C++, and MASM through calling argument lists just as you can within each language (for example, the argument list a, b and c in CALL MYSUB(a,b,c)). There are two ways to pass individual arguments:

- *By value*, which passes the argument's value.
- *By reference*, which passes the address of the arguments. On systems based on IA-32 architecture, Fortran, C, and C++ use 4-byte addresses. On systems based on Intel® 64 architecture and those based on IA-64 architecture, these languages use 8-byte addresses.

You need to make sure that for every call, the calling program and the called routine agree on how each argument is passed. Otherwise, the called routine receives bad data.

The Fortran technique for passing arguments changes depending on the calling convention specified. By default, Fortran passes all data by reference (except the hidden length argument of strings, which is passed by value).

If the ATTRIBUTES C option or, for Windows OS, the STDCALL option is used, the default changes to passing all data by value except arrays. If the procedure has the REFERENCE option as well as the C or STDCALL option, all arguments by default are passed by reference.

You can specify also argument options, VALUE and REFERENCE, to pass arguments by value or by reference. In mixed-language programming, it is a good idea to specify the passing technique explicitly rather than relying on defaults.

NOTE. On Windows operating systems, the compiler option `/iface` also establishes some default argument passing conventions (such as for hidden length of strings). See ATTRIBUTES Properties and Calling Conventions.

Examples of passing by reference and value for C and MASM follow. All are interfaces to the example Fortran subroutine `TESTPROC` below. The definition of `TESTPROC` declares how each argument is passed. The REFERENCE option is not strictly necessary in this example, but using it makes the argument's passing convention conspicuous.

```
SUBROUTINE TESTPROC( VALPARM, REFPARM )
  !DEC$ ATTRIBUTES VALUE :: VALPARM
  !DEC$ ATTRIBUTES REFERENCE :: REFPARM
  INTEGER VALPARM
  INTEGER REFPARM
END SUBROUTINE
```

In C and C++, all arguments are passed by value, except arrays, which are passed by reference to the address of the first member of the array. Unlike Fortran, C and C++ do not have calling-convention directives to affect the way individual arguments are passed. To pass non-array C data by reference, you must pass a pointer to it. To pass a C array by value, you must declare it as a member of a structure and pass the structure. The following C declaration sets up a call to the example Fortran `TESTPROC` subroutine:

For Linux OS:

```
extern void testproc_(
 int ValParm, int *RefParm );
```

For Windows OS:

```
extern void TESTPROC(
 int ValParm, int *RefParm );
```

In MASM (Windows OS only), arguments are passed by value by default. Arguments to be passed by reference are designated with PTR in the PROTO and PROC directives. For example:

```
TESTPROC PROTO, valparm:
 SDWORD, refparm: PTR SDWORD
```

To use an argument passed by value, use the value of the variable. For example:

```
mov eax, valparm ; Load value of argument
```

This statement places the value of valparm into the EAX register.

To use an argument passed by reference, use the address of the variable. For example:

```
mov ecx, refparm ; Load address of argument
mov eax, [ecx]   ; Load value of argument
```

These statements place the value of refparm into the EAX register.

The following table summarizes how to pass arguments by reference and value. An array name in C is equated to its starting address because arrays are normally passed by reference. You can assign the REFERENCE property to a procedure, as well as to individual arguments.

Table 39: Passing Arguments by Reference and Value

Language	ATTRIBUTE	Argument Type	To Pass by Reference	To Pass by Value
Fortran	Default	Scalars and derived types	Default	VALUE option
	C (or, for Windows OS, STDCALL) option	Scalars and derived types	REFERENCE option	Default
	Default	Arrays	Default	Cannot pass by value

Language	ATTRIBUTE	Argument Type	To Pass by Reference	To Pass by Value
	C (or, for Windows OS, STDCALL) option	Arrays	Default	Cannot pass by value
C/C++		Non-arrays	Pointer argument_name	Default
		Arrays	Default	Struct {type} array_name
Assembler MASM (Windows OS only)		All types	PTR	Default

This table does not describe argument passing of strings and Fortran 95/90 pointer arguments in Intel Fortran, which are constructed differently than other arguments. By default, Fortran passes strings by reference along with the string length. String length placement depends on whether the compiler option `-mixed-str-len-arg` (Linux OS and Mac OS X) or `/iface:mixed_str_len_arg` (Windows OS) is set immediately after the address of the beginning of the string. It also depends on whether -nomixed-str-len-arg (Linux OS and Mac OS X) or `/iface:nomixed_str_len_arg` (Windows OS) is set after all arguments.

Fortran 95/90 array pointers and assumed-shape arrays are passed by passing the address of the array descriptor.

For a discussion of the effect of attributes on passing Fortran 95/90 pointers and strings, see Handling Fortran Array Pointers and Allocatable Arrays and Handling Character Strings.

Using Modules in Mixed-Language Programming

Modules are the simplest way to exchange large groups of variables with C, because Intel Fortran modules are directly accessible from C/C++. The following example declares a module in Fortran, then accesses its data from C.

The Fortran code:

```
! F90 Module definition
   MODULE EXAMP
      REAL A(3)
```

```
      INTEGER I1, I2
      CHARACTER(80) LINE
      TYPE MYDATA
         SEQUENCE
         INTEGER N
         CHARACTER(30) INFO
      END TYPE MYDATA
   END MODULE EXAMP
```

The C code:

```
\* C code accessing module data *\
extern float EXAMP_mp_A[3];
extern int EXAMP_mp_I1, EXAMP_mp_I2;
extern char EXAMP_mp_LINE[80];
extern struct {
          int N;
          char INFO[30];
} EXAMP_mp_MYDATA;
```

When the C++ code resides in a `.cpp` file, C++ semantics are applied to external names, often resulting in linker errors. In this case, use the extern "C" syntax (see C/C++ Naming Conventions):

```
\* C code accessing module data in .cpp file*\
extern "C" float EXAMP_mp_A[3];
extern "C" int EXAMP_mp_I1, EXAMP_mp_I2;
extern "C" char EXAMP_mp_LINE[80];
extern "C" struct {
          int N;
          char INFO[30];
} EXAMP_mp_MYDATA;
```

You can define an interface to a C routine in a module, then use it like you would an interface to a Fortran routine. The C code is:

The C code:

```
 // C procedure
void pythagoras (float a, float b, float *c)
{
   *c = (float) sqrt(a*a + b*b);
}
```

When the C++ code resides in a `.cpp` file, use the extern "C" syntax (see C/C++ Naming Conventions):

```
// C procedure
extern "C" void pythagoras (float a, float b, float *c)
{
   *c = (float) sqrt(a*a + b*b);
}
```

The following Fortran code defines the module CPROC:

```
 ! Fortran 95/90 Module including procedure
   MODULE CPROC
      INTERFACE
         SUBROUTINE PYTHAGORAS (a, b, res)
          !DEC$ ATTRIBUTES C :: PYTHAGORAS
          !DEC$ ATTRIBUTES REFERENCE :: res
! res is passed by REFERENCE because its individual attribute
! overrides the subroutine's C attribute
            REAL a, b, res
! a and b have the VALUE attribute by default because
! the subroutine has the C attribute
         END SUBROUTINE
      END INTERFACE
   END MODULE
```

The following Fortran code calls this routine using the module CPROC:

```
 ! Fortran 95/90 Module including procedure
   USE CPROC
      CALL PYTHAGORAS (3.0, 4.0, X)
      TYPE *,X
   END
```

Using Common External Data in Mixed-Language Programming

Common external data structures include Fortran common blocks, and C structures and variables that have been declared global or external. All of these data specifications create external variables, which are variables available to routines outside the routine that defines them.

This section applies only to Fortran/C and, on Windows, Fortran/MASM mixed-language programs.

External variables are case sensitive, so the cases must be matched between different languages, as discussed in the section on naming conventions. Common external data exchange is described in the following sections:

- Using Global Variables
- Using Fortran Common Blocks and C Structures

Using Global Variables in Mixed-Language Programming

A variable can be shared between Fortran and C or MASM by declaring it as global (or `COMMON`) in one language and accessing it as an external variable in the other language.

In Fortran, a variable can access a global parameter by using the EXTERN option for ATTRIBUTES. For example:

```
    !DEC$ ATTRIBUTES C, EXTERN :: idata
   INTEGER idata (20)
```

EXTERN tells the compiler that the variable is actually defined and declared global in another source file. If Fortran declares a variable external with EXTERN, the language it shares the variable with must declare the variable global.

In C, a variable is declared global with the statement:

```
  int idata[20]; // declared as global (outside of any function)
```

MASM declares a parameter global (PUBLIC) with the syntax:

```
            PUBLIC [langtype] name
```

where *name* is the name of the global variable to be referenced, and the optional *langtype* is STDCALL or C. The option *langtype*, if present, overrides the calling convention specified in the .MODEL directive.

Conversely, Fortran can declare the variable global (COMMON) and other languages can reference it as external:

```
 ! Fortran declaring PI global
  REAL PI
  COMMON /PI/ PI ! Common Block and variable have the same name
```

In C, the variable is referenced as an external with the statement:

```
  //C code with external reference to PI
  extern float PI;
```

Note that the global name C references is the name of the Fortran common block, not the name of a variable within a common block. Thus, you cannot use blank common to make data accessible between C and Fortran. In the preceding example, the common block and the variable have the same name, which helps keep track of the variable between the two languages. Obviously, if a common block contains more than one variable they cannot all have the common block name. (See Using Fortran Common Blocks and C Structures.)

MASM and Assembly can also access Fortran global (COMMON) parameters with the ATTRIBUTES EXTERN directive. The syntax is:

```
EXTERN [langtype] name
```

where *name* is the name of the global variable to be referenced, and the optional *langtype* is STDCALL or C.

Using Fortran Common Blocks and C Structures

To reference C structures from Fortran common blocks and vice versa, you must take into account how common blocks and structures differ in their methods of storing member variables in memory. Fortran places common block variables into memory in order as close together as possible, with the following rules:

- A single BYTE, INTEGER(1), LOGICAL(1), or CHARACTER variable in common block list begins immediately following the previous variable or array in memory.
- All other types of single variables begin at the next even address immediately following the previous variable or array in memory.
- All arrays of variables begin on the next even address immediately following the previous variable or array in memory, except for CHARACTER arrays which always follow immediately after the previous variable or array.
- All common blocks begin on a four-byte aligned address.

Because of these padding rules, you must consider the alignment of C structure elements with Fortran common block elements and assure matching either by making all variables exactly equivalent types and kinds in both languages (using only 4-byte and 8-byte data types in both languages simplifies this) or by using the C pack pragmas in the C code around the C structure to make C data packing like Fortran data packing. For example:

```
#pragma pack(2)
struct {
       int N;
       char INFO[30];
} examp;
#pragma pack()
```

To restore the original packing, you must add #pragma pack( ) at the end of the structure. (Remember: Fortran module data can be shared directly with C structures with appropriate naming.)

Once you have dealt with alignment and padding, you can give C access to an entire common block or set of common blocks. Alternatively, you can pass individual members of a Fortran common block in an argument list, just as you can any other data item. Use of common blocks for mixed-language data exchange is discussed in the following sections:

- Accessing Common Blocks and C Structures Directly
- Passing the Address of a Common Block

Accessing Common Blocks and C Structures Directly

You can access Fortran common blocks directly from C by defining an external C structure with the appropriate fields, and making sure that alignment and padding between Fortran and C are compatible. The C and ALIAS ATTRIBUTES options can be used with a common block to allow mixed-case names.

As an example, suppose your Fortran code has a common block named Really, as shown:

```
  !DEC$ ATTRIBUTES ALIAS:'Really' :: Really
 REAL(4) x, y, z(6)
 REAL(8) ydbl
 COMMON / Really / x, y, z(6), ydbl
```

You can access this data structure from your C code with the following external data structures:

```
#pragma pack(2)
extern struct {
 float x, y, z[6];
 double ydbl;
} Really;
#pragma pack()
```

You can also access C structures from Fortran by creating common blocks that correspond to those structures. This is the reverse case from that just described. However, the implementation is the same because after common blocks and structures have been defined and given a common address (name), and assuming the alignment in memory has been dealt with, both languages share the same memory locations for the variables.

Passing the Address of a Common Block

To pass the address of a common block, simply pass the address of the first variable in the block, that is, pass the first variable by reference. The receiving C or C++ module should expect to receive a structure by reference.

In the following example, the C function initcb receives the address of a common block with the first variable named n, which it considers to be a pointer to a structure with three fields:

Fortran source code:

```
!
  INTERFACE
    SUBROUTINE initcb (BLOCK)
      !DEC$ ATTRIBUTES C :: initcb
      !DEC$ ATTRIBUTES REFERENCE :: BLOCK
      INTEGER BLOCK
    END SUBROUTINE
  END INTERFACE
```

```
!
  INTEGER n
  REAL(8) x, y
  COMMON /CBLOCK/n, x, y
   . . .
  CALL initcb( n )
```

C source code:

```
//
#pragma pack(2)
struct block_type
{
 int n;
 double x;
 double y;
};
#pragma pack()
//
void initcb( struct block_type *block_hed )
 {
  block_hed->n = 1;
  block_hed->x = 10.0;
  block_hed->y = 20.0;
}
```

Handling Data Types in Mixed-Language Programming

Handling Data Types in Mixed-Language Programming Overview

Even when you have reconciled calling conventions, naming conventions, and methods of data exchange, you must still be concerned with data types, because each language handles them differently. The following table lists the equivalent data types among Fortran, C, and MASM:

Table 40: Equivalent Data Types

Fortran Data Type	C Data Type	MASM Data Type
REAL(4)	float	REAL4
REAL(8)	double	REAL8
REAL(16)	---	---
CHARACTER(1)	unsigned char	BYTE
CHARACTER*(*)	See Handling Character Strings	

Fortran Data Type	C Data Type	MASM Data Type

COMPLEX(4)	struct complex4 {
	float real, imag;
	};
		COMPLEX4 STRUCT 4
		real REAL4 0
		imag REAL4 0
		COMPLEX4 ENDS

COMPLEX(8)	struct complex8 {
	double real, imag;
	};
		COMPLEX8 STRUCT 8
		real REAL8 0
		imag REAL8 0
		COMPLEX8 ENDS

COMPLEX(16)	---	---
All LOGICAL types	Use integer types for C, MASM	
INTEGER(1)	char	.sbyte
INTEGER(2)	short	.sword
INTEGER(4)	int	.sdword
INTEGER(8)	_int64	.qword

The following sections describe how to reconcile data types between the different languages:

- Handling Numeric, Complex, and Logical Data Types
- Handling Fortran 90 Array Pointers and Allocatable Arrays
- Handling Integer Pointers
- Handling Arrays and Fortran Array Descriptors
- Handling Character Strings
- Handling User-Defined Types

Handling Numeric, Complex, and Logical Data Types

Normally, passing numeric data does not present a problem. If a C program passes an unsigned data type to a Fortran routine, the routine can accept the argument as the equivalent signed data type, but you should be careful that the range of the signed type is not exceeded.

The table of Equivalent Data Types summarizes equivalent numeric data types for Fortran, MASM, and C/C++.

C, C++, and MASM do not directly implement the Fortran types COMPLEX(4), COMPLEX(8), and COMPLEX(16). However, you can write structures that are equivalent. The type COMPLEX(4) has two fields, both of which are 4-byte floating-point numbers; the first contains the real-number component, and the second contains the imaginary-number component. The type COMPLEX is equivalent to the type COMPLEX(4). The types COMPLEX(8) and COMPLEX(16) are similar except that each field contains an 8-byte or 16-byte floating-point number respectively.

NOTE. On systems based on IA-32 architecture, Fortran functions of type COMPLEX place a hidden COMPLEX argument at the beginning of the argument list. C functions that implement such a call from Fortran must declare this hidden argument explicitly, and use it to return a value. The C return type should be void.

Following are the C/C++ structure definitions for the Fortran COMPLEX types:

```
struct complex4 {
  float real, imag;
};
struct complex8 {
  double real, imag;
};
```

The MASM structure definitions for the Fortran COMPLEX types follow:

```
 COMPLEX4 STRUCT 4
  real REAL4 0
  imag REAL4 0
 COMPLEX4 ENDS
 COMPLEX8 STRUCT 8
  real REAL8 0
  imag REAL8 0
 COMPLEX8 ENDS
```

A Fortran LOGICAL(2) is stored as a 2-byte indicator value (0=false, and the `-fpscomp [no]logicals` (Linux* OS and Mac OS* X)or `/fpscomp:[no]logicals` (Windows* OS) compiler option determines how true values are handled). A Fortran LOGICAL(4) is stored as a 4-byte indicator value, and LOGICAL(1) is stored as a single byte. The type LOGICAL is the same as LOGICAL(4), which is equivalent to type int in C.

You can use a variable of type LOGICAL in an argument list, module, common block, or global variable in Fortran and type int in C for the same argument. Type LOGICAL(4) is recommended instead of the shorter variants for use in common blocks.

The C++ class type has the same layout as the corresponding C struct type, unless the class defines virtual functions or has base classes. Classes that lack those features can be passed in the same way as C structures.

Returning Complex Type Data

If a Fortran program expects a procedure to return a `COMPLEX` or `DOUBLE COMPLEX` value, the Fortran compiler adds an additional argument to the beginning of the called procedure argument list. This additional argument is a pointer to the location where the called procedure must store its result.

The example below shows the Fortran code for returning a complex data type procedure called `WBAT` and the corresponding C routine.

Example of Returning Complex Data Types from C to Fortran

Fortran code

```
COMPLEX BAT, WBAT
REAL X, Y
BAT = WBAT ( X, Y )
```

Corresponding C Routine

Linux example:

```
struct _mycomplex { float real;
 float imag; };
typedef struct _mycomplex _single_complex;

void wbat_ (_single_complex *location, float *x, float *y){
*location->real = *x;
*location->imag = *y;
return;
}
```

Windows OS example:

```
struct _mycomplex { float real, imag };
typedef struct _mycomplex _single_complex;

void WBAT (_single_complex location, float *x, float *y)
{
float realpart;
float imaginarypart;
... program text, producing realpart and
imaginarypart...
*location.real = realpart;
*location.imag = imaginarypart;
}
```

In the above example, the following restrictions and behaviors apply:

- The argument `location` does not appear in the Fortran call; it is added by the compiler.

- The C subroutine must copy the result's real and imaginary parts correctly into location.
- The called procedure is type void.

If the function returned a `DOUBLE COMPLEX` value, the type `float` would be replaced by the type `double` in the definition of `location` in `WBAT`.

Handling Fortran Array Pointers and Allocatable Arrays

The following affects how Fortran 95/90 array pointers and arrays are passed:

- the `ATTRIBUTES` properties in effect
- the `INTERFACE`, if any, of the procedure they are passed to>

If the `INTERFACE` declares the array pointer or array with deferred shape (for example, `ARRAY(:)`), its descriptor is passed. This is true for array pointers and all arrays, not just allocatable arrays. If the `INTERFACE` declares the array pointer or array with fixed shape, or if there is no interface, the array pointer or array is passed by base address as a contiguous array, which is like passing the first element of an array for contiguous array slices.

When a Fortran 95/90 array pointer or array is passed to another language, either its descriptor or its base address can be passed.

The following shows how allocatable arrays and Fortran 95/90 array pointers are passed with different attributes in effect:

- If the property of the array pointer or array is not included or is REFERENCE, it is passed by descriptor, regardless of the property of the passing procedure .
- If the property of the array pointer or array is VALUE, an error is returned, regardless of the property of the passing procedure.

Note that the VALUE option cannot be used with descriptor-based arrays.

When you pass a Fortran array pointer or an array by descriptor to a non-Fortran routine, that routine needs to know how to interpret the descriptor. Part of the descriptor is a pointer to address space, as a C pointer, and part of it is a description of the pointer or array properties, such as its rank, stride, and bounds.

For information about the Intel Fortran array descriptor format, see Handling Arrays and Fortran Array Descriptors.

Fortran 95/90 pointers that point to scalar data contain the address of the data and are not passed by descriptor.

Handling Integer Pointers

Intel® Fortran integer pointers (also known as Cray*-style pointers) are not the same as Fortran 90 pointers, but are instead like C pointers. On systems based on IA-32 architecture, integer pointers are 4-byte `INTEGER` quantities. On systems based on Intel® 64 architecture and those based on IA-64 architecture, integer pointers are 8-byte `INTEGER` quantities.

When passing an integer pointer to a routine written in another language:

- The argument should be declared in the non-Fortran routine as a pointer of the appropriate data type.
- The argument passed from the Fortran routine should be the integer pointer name, not the pointee name.

Fortran main program:

```
! Fortran main program.
INTERFACE
SUBROUTINE Ptr_Sub (p)
!DEC$ ATTRIBUTES C, DECORATE, ALIAS:'Ptr_Sub' :: Ptr_Sub
INTEGER (KIND=INT_PTR_KIND()) p
END SUBROUTINE Ptr_Sub
END INTERFACE
REAL A(10), VAR(10)
POINTER (p, VAR) ! VAR is the pointee
! p is the integer pointer
p = LOC(A)
CALL Ptr_Sub (p)
WRITE(*,*) 'A(4) = ', A(4)
END
!
```

On systems using Intel® 64 architecture and IA-64 architecture, the declaration for p in the INTERFACE block is equivalent to INTEGER(8) p and on systems using IA-32 architecture, it is equivalent to INTEGER (4) p.

C subprogram:

```
   //C subprogram
void Ptr_Sub (float *p)
{
p[3] = 23.5;
}
```

When the main Fortran program and C function are built and executed, the following output appears:

```
A(4) = 23.50000
```

When receiving a pointer from a routine written in another language:

- The argument should be declared in the non-Fortran routine as a pointer of the appropriate data type and passed as usual.
- The argument received by the Fortran routine should be declared as an integer pointer name and the `POINTER` statement should associate it with a pointee variable of the appropriate data type (matching the data type of the passing routine). When inside the Fortran routine, use the pointee variable to set and access what the pointer points to.

Fortran subroutine:

```
! Fortran subroutine.
    SUBROUTINE Iptr_Sub (p)
    !DEC$ ATTRIBUTES C, DECORATE, ALIAS:'Iptr_Sub' :: Iptr_Sub
     INTEGER (KIND=INT_PTR_KIND()) p
       integer VAR(10)
       POINTER (p, VAR)
       OPEN (8, FILE='STAT.DAT')
       READ (8, *) VAR(4) ! Read from file and store the
                          ! fourth element of VAR
    END SUBROUTINE Iptr_Sub
!
//C main program
extern void Iptr_Sub(int *p);
main ( void )
```

C Main Program:

```
//C main program
extern void Iptr_Sub(int *p);
main ( void )
{
int a[10];
Iptr_Sub (&a[0]);
printf("a[3] = %i\n", a[3]);
}
```

When the main C program and Fortran subroutine are built and executed, the following output appears if the `STAT.DAT` file contains 4:

```
a[3] = 4
```

Handling Arrays and Fortran Array Descriptors

Fortran 95/90 allows arrays to be passed as array elements, as array subsections, or as whole arrays referenced by array name. Within Fortran, array elements are ordered in column-major order, meaning the subscripts of the lowest dimensions vary first.

When using arrays between Fortran and another language, differences in element indexing and ordering must be taken into account. You must reference the array elements individually and keep track of them. Array indexing is a source-level consideration and involves no difference in the underlying data.

Fortran and C arrays differ in two ways:

- The value of the lower array bound is different. By default, Fortran indexes the first element of an array as 1. C and C++ index it as 0. Fortran subscripts should therefore be one higher. (Fortran also provides the option of specifying another integer lower bound.)
- In arrays of more than one dimension, Fortran varies the left-most index the fastest, while C varies the right-most index the fastest. These are sometimes called column-major order and row-major order, respectively.

In C, the first four elements of an array declared as X[3][3] are:

```
X[0][0] X[0][1] X[0][2] X[1][0]
```

In Fortran, the first four elements are:

```
X(1,1) X(2,1) X(3,1) X(1,2)
```

The order of indexing extends to any number of dimensions you declare. For example, the C declaration:

```
int arr1[2][10][15][20];
```

is equivalent to the Fortran declaration:

```
INTEGER arr1( 20, 15, 10, 2 )
```

The constants used in a C array declaration represent extents, not upper bounds as they do in other languages. Therefore, the last element in the C array declared as int arr[5][5] is arr[4][4], not arr[5][5].

The following table shows equivalencies for array declarations.

Language	Array Declaration	Array Reference from Fortran
Fortran	`DIMENSION` x(i, k) -or- *type* x(i, k)	x(i, k)
C/C++	*type* x[k] [i]	x(i -1, k -1)

Handling Arrays in Visual Basic and MASM

The following information on Visual Basic and MASM applies to Windows operating systems only.

To pass an array from Visual Basic to Fortran, pass the first element of the array. By default, Visual Basic passes variables by reference, so passing the first element of the array will give Fortran the starting location of the array, just as Fortran expects. Visual Basic indexes the first array element as 0 by default, while Fortran by default indexes it as 1. Visual Basic indexing can be set to start with 1 using the statement:

```
Option Base 1
```

Alternatively, in the array declaration in either language you can set the array lower bound to any integer in the range -32,768 to 32,767. For example:

```
' In Basic
Declare Sub FORTARRAY Lib "fortarr.dll" (Barray as Single)
DIM barray (1 to 3, 1 to 7) As Single
Call FORTARRAY(barray (1,1))
! In Fortran
Subroutine FORTARRAY(arr)
  REAL arr(1:3,1:7)
```

In MASM, arrays are one-dimensional and array elements must be referenced byte-by-byte. The assembler stores elements of the array consecutively in memory, with the first address referenced by the array name. You then access each element relative to the first, skipping the total number of bytes of the previous elements. For example:

```
xarray    REAL4     1.1, 2.2, 3.3, 4.4 ; initializes
                     ; a four element array with
                     ; each element 4 bytes
```

Referencing xarray in MASM refers to the first element, the element containing 1.1. To refer to the second element, you must refer to the element 4 bytes beyond the first with xarray[4] or xarray+4. Similarly:

```
yarray     BYTE      256 DUP     ; establishes a
               ; 256 byte buffer, no initialization
zarray SWORD 100 DUP(0) ; establishes 100
               ; two-byte elements, initialized to 0
```

Intel Fortran Array Descriptor Format

For cases where Fortran 95/90 needs to keep track of more than a pointer memory address, the Intel Fortran Compiler uses an *array descriptor*, which stores the details of how an array is organized.

When using an explicit interface (by association or procedure interface block), Intel Fortran generates a descriptor for the following types of array arguments:

- Pointers to arrays (array pointers)
- Assumed-shape arrays
- Allocatable array

Certain data structure arguments do not use a descriptor, even when an appropriate explicit interface is provided. For example, explicit-shape and assumed-size arrays do not use a descriptor. In contrast, array pointers and allocatable arrays use descriptors regardless of whether they are used as arguments.

When calling between Intel Fortran and a non-Fortran language (such as C), using an *implicit* interface allows the array argument to be passed *without* an Intel Fortran descriptor. However, for cases where the called routine needs the information in the Intel Fortran descriptor, declare the routine with an *explicit* interface and specify the dummy array as either an assumed-shape array or with the pointer attribute.

You can associate a Fortran 95/90 pointer with any piece of memory, organized in any way desired (so long as it is "rectangular" in terms of array bounds). You can also pass Fortran 95/90 pointers to other languages, such as C, and have the other language correctly interpret the descriptor to obtain the information it needs.

However, using array descriptors can increase the opportunity for errors and the corresponding code is not portable. In particular, be aware of the following:

- If the descriptor is not defined correctly, the program may access the wrong memory address, possibly causing a General Protection Fault.
- Array descriptor formats are specific to each Fortran compiler. Code that uses array descriptors is *not*portable to other compilers or platforms. For example, the current Intel Fortran array descriptor format differs from the array descriptor format for Intel Fortran 7.0.
- The array descriptor format may change in the future.
- If the descriptor was built by the compiler, it cannot be modified by the user. Changing fields of existing descriptors is illegal.

The components of the current Intel Fortran array descriptor on systems using IA-32 architecture are as follows:

- The first longword (bytes 0 to 3) contains the base address. The base address plus the offset defines the first memory location (start) of the array.

- The second longword (bytes 4 to 7) contains the size of a single element of the array.
- The third longword (bytes 8 to 11) contains the A0 offset. The A0 offset is added to the base address to calculate the address for the element with all indices zero, even if that is outside the bounds of the actual array. This is helpful in computing array element addresses.
- The fourth longword (bytes 12 to 15) contains a set of flags used to store information about the array. This includes:
  - bit 1 (0x01): array is defined -- set if the array has been defined (storage allocated)
  - bit 2 (0x02): no deallocation allowed -- set if the array pointed to cannot be deallocated (that is, it is an explicit array target)
  - bit 3 (0x04): array is contiguous -- set if the array pointed to is a contiguous whole array or slice.
- The fifth longword (bytes 16 to 19) contains the number of dimensions (rank) of the array.
- The sixth longword (bytes 20 to 23) is reserved and should not be explicitly set.
- The remaining longwords (bytes 24 to 107) contain information about each dimension (up to seven). Each dimension is described by three additional longwords:
  - The number of elements (extent)
  - The distance between the starting address of two successive elements in this dimension, in bytes.
  - The lower bound

An array of rank one requires three additional longwords for a total of nine longwords (6 + 3*1) and ends at byte 35. An array of rank seven is described in a total of 27 longwords (6 + 3*7) and ends at byte 107.

For example, consider the following declaration:

```
 integer,target :: a(10,10)
integer,pointer :: p(:,:)
p => a(9:1:-2,1:9:3)
call f(p)
.
.
.
```

The descriptor for actual argument p would contain the following values:

- The first longword (bytes 0 to 3) contains the base address (assigned at run-time).
- The second longword (bytes 4 to 7) is set to 4 (size of a single element).

- The third longword (bytes 8 to 11) contains the A0 offset of -112.
- The fourth longword (bytes 12 to 15) contains 3 (array is defined and deallocation is not allowed).
- The fifth longword (bytes 16 to 19) contains 2 (rank).
- The sixth longword (bytes 20-23) is reserved.
- The seventh, eighth, and ninth longwords (bytes 24 to 35) contain information for the first dimension, as follows:
  - 5 (extent)
  - -8 (distance between elements)
  - 9 (the lower bound)
- For the second dimension, the tenth, eleventh, and twelfth longwords (bytes 36 to 47) contain:
  - 3 (extent)
  - 120 (distance between elements)
  - 1 (the lower bound)
- Byte 47 is the last byte for this example.

NOTE. The format for the descriptor on systems using Intel® 64 architecture and those using IA-64 architecture is identical to that on systems using IA-32 architecture, except that all fields are 8-bytes long, instead of 4-bytes.

Handling Large Arrays

When compiling a program with an array greater than 2GB on systems using Intel® 64 architecture and running Linux OS, you may need to specify certain compiler options. Specifically, you may need to use either the `-mcmodel=medium` or `-mcmodel=large` compiler option and also the `-shared-intel` option. For more information, see Specifying Memory Models to use with Systems Based on Intel® 64 Architecture.

Handling Character Strings

By default, Intel® Fortran passes a hidden length argument for strings. The hidden length argument consists of an unsigned 4-byte integer (for systems based on IA-32 architecture) or unsigned 8-byte integer (for systems based on Intel® 64 architecture and those based on IA-64 architecture), always passed by value, added to the end of the argument list. You can alter the default way strings are passed by using attributes. The following table shows the effect of various attributes on passed strings.

Table 42: Effect of ATTRIBUTES Options on Character Strings Passed as Arguments

Argument	Default	C	C, REFERENCE	STDCALL (Windows* OS)	STDCALL, REFERENCE (Windows* OS)
String	Passed by reference, along with length	First character converted to INTEGER(4) and passed by value	Passed by reference, along with length	First character converted to INTEGER(4) and passed by value	Passed by reference, along with length
String with VALUE option	Error	First character converted to INTEGER(4) and passed by value	First character converted to INTEGER(4) and passed by value	First character converted to INTEGER(4) and passed by value	First character converted to INTEGER(4) and passed by value
String with REFERENCE option	Passed by reference, possibly along with length	Passed by reference, no length	Passed by reference, no length	Passed by reference, no length	Passed by reference, no length

The important things to note about the above table are:

- Character strings without the VALUE or REFERENCE attribute that are passed to C or STDCALL routines are not passed by reference. Instead, only the first character is passed and it is passed by value.
- Character strings with the VALUE option passed to C or STDCALL routines are not passed by reference. Instead, only the value of the first character is passed.

- For string arguments with default ATTRIBUTES, ATTRIBUTES C, REFERENCE, or ATTRIBUTES STDCALL, REFERENCE:
  - When -nomixed-str-len-arg (Linux OS and Mac OS X) or /iface:nomixed_str_len_arg (Windows OS) is set, the length of the string is pushed (by value) on the stack after all of the other arguments. This is the default.
  - When -mixed-str-len-arg (Linux OS and Mac OS X) or /iface:mixed_str_len_arg (Windows OS) is set, the length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.
- For string arguments passed by reference with default ATTRIBUTES:
  - When -nomixed-str-len-arg (Linux OS and Mac OS X) or /iface:nomixed_str_len_arg is set, the length of the string is not available to the called procedure. This is the default.
  - When -mixed-str-len-arg (Linux OS and Mac OS X) or /iface:mixed_str_len_arg is set, the length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.

Since all strings in C are pointers, C expects strings to be passed by reference, without a string length. In addition, C strings are null-terminated while Fortran strings are not. There are two basic ways to pass strings between Fortran and C: convert Fortran strings to C strings, or write C routines to accept Fortran strings.

To convert a Fortran string to C, choose a combination of attributes that passes the string by reference without length, and null terminate your strings. For example:

```
INTERFACE
  SUBROUTINE Pass_Str (string)
    !DEC$ ATTRIBUTES C, DECORATE,ALIAS:'Pass_Str' :: Pass_Str
    CHARACTER*(*) string
    !DEC$ ATTRIBUTES REFERENCE :: string
  END SUBROUTINE
END INTERFACE
CHARACTER(40) forstring
DATA forstring /'This is a null-terminated string.'C/
```

The following example shows the extension of using the null-terminator for the string in the Fortran DATA statement:

```
DATA forstring /'This is a null-terminated string.'C/
```

The C interface is:

```
void Pass_Str (char *string)
```

To get your C routines to accept Fortran strings, C must account for the length argument passed along with the string address. For example:

```
! Fortran code
INTERFACE
  SUBROUTINE Pass_Str (string)
  CHARACTER*(*) string
END INTERFACE
```

The C routine must expect two arguments:

```
void pass_str (char *string, unsigned int length_arg )
```

This interface handles the hidden-length argument, but you must still reconcile C strings that are null-terminated and Fortran strings that are not. In addition, if the data assigned to the Fortran string is less than the declared length, the Fortran string will be blank padded.

Rather than trying to handle these string differences in your C routines, the best approach in Fortran/C mixed programming is to adopt C string behavior whenever possible. An added benefit for using C strings on Windows* operating systems is that Windows API routines and most C library functions expect null-terminated strings.

Fortran functions that return a character string using the syntax `CHARACTER*(*)` place a hidden string argument and the length of the string at the beginning of the argument list.

C functions that implement such a Fortran function call must declare this hidden string argument explicitly and use it to return a value. The C return type should be void. However, you are more likely to avoid errors by not using character-string return functions. Use subroutines or place the strings into modules or global variables whenever possible.

Handling Character Strings in Visual Basic and MASM

The following information on Visual Basic and MASM applies to Windows operating systems only.

Visual Basic strings must be passed by value to Fortran. Visual Basic strings are actually stored as structures containing length and location information. Passing by value dereferences the structure and passes just the string location, as Fortran expects. For example:

```
! In Basic
 Declare Sub forstr  Lib "forstr.dll" (ByVal Bstring as String)
 DIM bstring As String * 40 Fixed-length string
 CALL forstr(bstring)
! End Basic code
! In Fortran
 SUBROUTINE forstr(s)
 !DEC$ ATTRIBUTES STDCALL :: forstr
 !DEC$ ATTRIBUTES REFERENCE :: s
```

```
CHARACTER(40) s
s = 'Hello, Visual Basic!'
END
```

The Fortran directive !DEC$ ATTRIBUTES STDCALL and the ATTRIBUTES REFERENCE property on variable arguments together inform Fortran not to expect the hidden length arguments to be passed from the Visual Basic calling program. The name in the Visual Basic program is specified as lowercase since STDCALL makes the Fortran name lowercase.

MASM does not add either a string length or a null character to strings by default. To append the string length, use the syntax:

lenstring BYTE "String with length", LENGTHOF lenstring

To add a null character, append it by hand to the string:

```
nullstring BYTE "Null-terminated string", 0
```

Returning Character Data Types

If a Fortran program expects a function to return data of type CHARACTER, the Fortran compiler adds two additional arguments to the beginning of the called procedure's argument list:

- The first argument is a pointer to the location where the called procedure should store the result.
- The second is the maximum number of characters that must be returned, padded with blank spaces if necessary.

The called routine must copy its result through the address specified in the first argument. The following example shows the Fortran code for a return character function called MAKECHARS and a corresponding C routine.

Example of Returning Character Types from C to Fortran

Fortran code

```
CHARACTER*10 CHARS, MAKECHARS
DOUBLE PRECISION X, Y
CHARS = MAKECHARS( X, Y )
```

Corresponding C Routine

```
void MAKECHARS ( result, length, x, y );
char *result;
int length;
double *x, *y;
{
...program text, producing returnvalue...
for (i = 0; i < length; i++ ) {
```

```
result[i] = returnvalue[i];
}
}
```

In the above example, the following restrictions and behaviors apply:

- The function's length and result do not appear in the call statement; they are added by the compiler.
- The called routine must copy the result string into the location specified by `result`; it must not copy more than `length` characters.
- If fewer than `length` characters are returned, the return location should be padded on the right with blanks; Fortran does not use zeros to terminate strings.
- The called procedure is type `void`.
- On Windows, you must use uppercase names for C routines or Microsoft attributes and `INTERFACE` blocks to make the calls using lower case.

Handling User-Defined Types

Fortran 95/90 supports user-defined types (data structures similar to C structures). User-defined types can be passed in modules and common blocks just as other data types, but the other language must know the type's structure. For example:

Fortran Code:

```
TYPE LOTTA_DATA
   SEQUENCE
   REAL A
   INTEGER B
   CHARACTER(30) INFO
   COMPLEX CX
   CHARACTER(80) MOREINFO
END TYPE LOTTA_DATA
TYPE (LOTTA_DATA) D1, D2
COMMON /T_BLOCK/ D1, D2
```

In the Fortran code above, the SEQUENCE statement preserves the storage order of the derived-type definition.

C Code:

```
/* C code accessing D1 and D2 */
extern struct {
  struct {
     float a;
     int b;
     char info[30];
```

```
      struct {
         float real, imag;
         } cx;
      char moreinfo[80];
   } d1, d2;
} T_BLOCK;
```

Intel(R) Fortran/Visual Basic* Mixed-Language Programs

Interoperability with C

It is often desirable to have a program which contains both Fortran and C code, and in which routines written in one language are able to call routines written in the other. The Intel® Fortran compiler supports the Fortran 2003 standardized mechanism for allowing Fortran code to reliably communicate (or *interoperate*) with C code. The following describes interoperability requirements for types, variables, and procedures.

Interoperability of Intrinsic Types

The intrinsic module ISO_C_BINDING contains named constants that hold kind type parameter values for intrinsic types.

The more commonly used types are included in the following table. The following applies:

- Integer types in Fortran are always signed. In C, integer types may be specified as signed or unsigned, but are unsigned by default.
- The values of C_LONG, C_SIZE_T, C_LONG_DOUBLE, AND C_LONG_DOUBLE_COMPLEX are different on different platforms.

Named constant from ISO_C_BINDING (kind type parameter if value is positive)	**C type**	**Equivalent Fortran type**
C_SHORT	short int	INTEGER(KIND=2)
C_INT	int	INTEGER(KIND=4)
C_LONG	long int	INTEGER (KIND=4 or 8)
C_LONG_LONG	long long int	INTEGER(KIND=8)

C_SIGNED_CHAR	signed char unsigned char	INTEGER(KIND=1)
C_SIZE_T	size_t	INTEGER(KIND=4 or 8)
C_INT8_T	int8_t	INTEGER(KIND=1)
C_INT16_T	int16_t	INTEGER(KIND=2)
C_INT32_T	int32_t	INTEGER(KIND=4)
C_INT64_T	int64_t	INTEGER(KIND=8)
C_FLOAT	float	REAL(KIND=4)
C_DOUBLE	double	REAL(KIND=8)
C_LONG_DOUBLE	long double	REAL(KIND=8 or 16)
C_FLOAT_COMPLEX	float _Complex	COMPLEX(KIND=4)
C_DOUBLE_COMPLEX	double _Complex	COMPLEX(KIND=8)
C_LONG_DOUBLE_COMPLEX	long double _Complex	COMPLEX(KIND=8 or 16)
C_BOOL	_Bool	LOGICAL(KIND=1)
C_CHAR	char	CHARACTER(LEN=1)

While there are named constants for all possible C types, every type is not necessarily supported on every processor. Lack of support is indicated by a negative value for the constant in the module.

For a character type to be interoperable, you must either omit the length type parameter or specify it using an initialization expression whose value is one.

Interoperability with C Pointers

For interoperating with C pointers, the module ISO_C_BINDING contains the derived types C_PTR and C_FUNPTR, which are interoperable with C object and function type pointers, respectively.

These types, as well as certain procedures in the module, provide the mechanism for passing dynamic arrays between the two languages. Because its elements need not be contiguous in memory, a Fortran pointer target or assumed-shape array cannot be passed to C. However, you can pass an allocated allocatable array to C, and you can associate an array allocated in C with a Fortran pointer.

Interoperability of Derived Types

For a derived type to be interoperable with C, you must specify the BIND(C) attribute:

```
TYPE, BIND(C) :: MYTYPE
```

Additionally, as shown in the examples that follow, each component must have an interoperable type and interoperable type parameters, must not be a pointer, and must not be allocatable. This allows Fortran and C types to correspond.

```
typedef struct {
int m, n;
float r;
} myctype
```

The above is interoperable with the following:

```
USE, INTRINSIC :: ISO_C_BINDING
TYPE, BIND(C) :: MYFTYPE
INTEGER(C_INT) :: I, J
REAL(C_FLOAT) :: S
END TYPE MYFTYPE
```

Interoperability of Variables

A scalar Fortran variable is interoperable if its type and type parameters are interoperable and it is not a pointer.

An array Fortran variable is interoperable if its type and type parameters are interoperable and it has an explicit shape or assumed size. It interoperates with a C array of the same type, type parameters, and shape, but with subscripts reversed.

For example, a Fortran array declared as `INTEGER :: A(18, 3:7, *)` is interoperable with a C array declared as `int b[][5][18]`.

Interoperability of Procedures

For a procedure to be interoperable, it must have an explicit interface and be declared with the BIND attribute, as shown in the following:

```
FUNCTION FUNC(I, J, K, L, M), BIND(C)
```

In the case of a function, the result must be scalar and interoperable.

A procedure has an associated binding label, which is global in scope. This label is the name by which the C processor knows it and is, by default, the lower-case version of the Fortran name. For example, the above function has the binding label func. You can specify an alternative binding label as follows:

```
FUNCTION FUNC(I, J, K, L, M), BIND(C, NAME='myC_Func')
```

All dummy arguments must be interoperable. Furthermore, you must ensure that either the Fortran routine uses the VALUE attribute for scalar dummy arguments, or that the C routine receives these scalar arguments as pointers to the scalar values. Consider the following call to this C function:

```
intc_func(int x, int *y);
```

As shown here, the interface for the Fortran call to c_func must have x passed with the VALUE attribute, but y should not have the VALUE attribute, since it is received as a pointer:

```
INTERFACE
INTEGER (C_INT) FUNCTION C_FUNC(X, Y) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
IMPLICIT NONE
INTEGER (C_INT), VALUE :: X
INTEGER (C_INT) :: Y
END FUNCTION C_FUNC
END INTERFACE
```

Alternatively, the declaration for y can be specified as a C_PTR passed by value:

```
TYPE (C_PTR), VALUE :: Y
```

To pass a scalar Fortran variable of type character, the character length must be one.

Interoperability of Global Data

A module variable or a common block can interoperate with a C global variable if the Fortran entity uses the BIND attribute and the members of that entity are also interoperable. For example, consider the entities C_EXTERN, C2, COM and SINGLE in the following module:

```
MODULE LINK_TO_C_VARS
USE, INTRINSIC :: ISO_C_BINDING
INTEGER(C_INT), BIND(C) :: C_EXTERN
INTEGER(C_LONG) :: C2
BIND(C, NAME='myVariable') :: C2
COMMON /COM/ R,S
REAL(C_FLOAT) :: R,S,T
BIND(C) :: /COM/, /SINGLE/
COMMON /SINGLE/ T
END MODULE LINK_TO_C_VARS
```

These can interoperate with the following C external variables:

```
int c_extern;
long myVariable;
struct {float r, s;} com;
float single;
```

Example of Fortran Calling C

The following example calls a C function.

C Function Prototype:

```
int C_Library_Function(void* sendbuf, int sendcount, int *recvcounts);
```

Fortran Modules:

```
MODULE FTN_C_1
USE, INTRINSIC :: ISO_C_BINDING
END MODULE FTN_C_1

MODULE FTN_C_2
INTERFACE
INTEGER (C_INT) FUNCTION C_LIBRARY_FUNCTION &
(SENDBUF, SENDCOUNT, RECVCOUNTS) &
BIND(C, NAME='C_Library_Function')
USE FTN_C_1
IMPLICIT NONE
TYPE (C_PTR), VALUE :: SENDBUF
INTEGER (C_INT), VALUE :: SENDCOUNT
TYPE (C_PTR), VALUE :: RECVCOUNTS
END FUNCTION C_LIBRARY_FUNCTION
END INTERFACE
END MODULE FTN_C_2
```

Fortran Calling Sequence:

```
USE, INTRINSIC :: ISO_C_BINDING, ONLY: C_INT, C_FLOAT, C_LOC
USE FTN_C_2
...
REAL (C_FLOAT), TARGET :: SEND(100)
INTEGER (C_INT) :: SENDCOUNT
INTEGER (C_INT), ALLOCATABLE, TARGET :: RECVCOUNTS(100)
...
ALLOCATE( RECVCOUNTS(100) )
...
CALL C_LIBRARY_FUNCTION(C_LOC(SEND), SENDCOUNT, &
C_LOC(RECVCOUNTS))
...
```

Example of C Calling Fortran

The following example calls a Fortran subroutine called SIMULATION. This subroutine corresponds to the C void function simulation.

Fortran Code:

```
SUBROUTINE SIMULATION(ALPHA, BETA, GAMMA, DELTA, ARRAYS) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
IMPLICIT NONE
INTEGER (C_LONG), VALUE :: ALPHA
REAL (C_DOUBLE), INTENT(INOUT) :: BETA
INTEGER (C_LONG), INTENT(OUT) :: GAMMA
REAL (C_DOUBLE),DIMENSION(*),INTENT(IN) :: DELTA
TYPE, BIND(C) :: PASS
INTEGER (C_INT) :: LENC, LENF
TYPE (C_PTR) :: C, F
END TYPE PASS
TYPE (PASS), INTENT(INOUT) :: ARRAYS
REAL (C_FLOAT), ALLOCATABLE, TARGET, SAVE :: ETA(:)
REAL (C_FLOAT), POINTER :: C_ARRAY(:)
...
! Associate C_ARRAY with an array allocated in C
CALL C_F_POINTER (ARRAYS%C, C_ARRAY, (/ARRAYS%LENC/) )
...
! Allocate an array and make it available in C
ARRAYS%LENF = 100
ALLOCATE (ETA(ARRAYS%LENF))
ARRAYS%F = C_LOC(ETA)
...
END SUBROUTINE SIMULATION
```

C Struct Declaration

```
struct pass {int lenc, lenf; float *c, *f;};
```

C Function Prototype:

```
void simulation(long alpha, double *beta, long *gamma, double delta[], struct pass *arrays);
```

C Calling Sequence:

```
simulation(alpha, &beta, &gamma, delta, &arrays);
```

Compiling and Linking Intel® Fortran/C Programs

Your application can contain both C and Fortran source files. If your main program is a Fortran source file (myprog.for) that calls a routine written in C (cfunc.c), you can use the following sequence of commands to build your application.

Linux* OS and Mac OS* X:

```
icc -c cfunc.c
ifort -o myprog myprog.for cfunc.o
```

Windows* OS:

```
icl /c cfunc.c
ifort myprog.for cfunc.obj
 /link /out:myprog.exe
```

The `icc` or `icl` command for Intel® C++ or the `cl` command (for Microsoft Visual C++*) compiles `cfunc.c`. The `-c` or `/c` option specifies that the linker is not called. This command creates `cfunc.o` (Linux OS and Mac OS X) or `cfunc.obj` (Windows OS).

The ifort command compiles `myprog.for` and links `cfunc.o` (Linux OS and Mac OS X) or `cfunc.obj` (Windows OS) with the object file created from `myprog.for` to create the executable.

Additionally, on Linux OS and Mac OS X, you may need to specify one or more of the following options:

- Use the -cxxlib compiler option to tell the compiler to link using the C++ run-time libraries provided by gcc. By default, C++ libraries are not linked with Fortran applications.
- Use the `-fexceptions` compiler option to enable C++ exception handling table generation so C++ programs can handle C++ exceptions when there are calls to Fortran routines on the call stack. This option causes additional information to be added to the object file that is required during C++ exception handling. By default, mixed Fortran/C++ applications abort in the Fortran code if a C++ exception is thrown.
- Use the `-nofor_main` compiler option if your C/C++ program calls an Intel Fortran subprogram, as shown:

```
icc -c  cmain.c
ifort -nofor_main cmain.o fsub.f90
```

Calling C Procedures from an Intel® Fortran Program

Naming Conventions

By default, the Fortran compiler converts function and subprogram names to lower case for Linux OS and Mac OS X and upper case for Windows OS. The C compiler never performs case conversion. A C procedure called from a Fortran program must, therefore, be named using the appropriate case. For example, consider the following calls:

`CALL PROCNAME()`	The C procedure must be named `PROCNAME`.

`X=FNNAME()`	The C procedure must be named `FNNAME`

In the first call, any value returned by `PROCNAME` is ignored. In the second call to a function, `FNNAME` must return a value.

Passing Arguments Between Fortran and C Procedures

By default, Fortran subprograms pass arguments by reference; that is, they pass a pointer to each actual argument rather than the value of the argument. C programs, however, pass arguments by value. Consider the following:

- When a Fortran program calls a C function, the C function's formal arguments must be declared as pointers to the appropriate data type.
- When a C program calls a Fortran subprogram, each actual argument must be specified explicitly as a pointer.

For Windows systems using IA-32 architecture only, you can alter the default calling convention. You can use either the `/iface:stdcall` option (`stdcall`) or the `/iface:cvf` option (Compaq* and Powerstation compatibility) to change the default calling convention, or the `VALUE` or C attributes in an explicit interface using the ATTRIBUTES directive. For more information on the ATTRIBUTES directive, see the Intel® Fortran Language Reference.

Both options cause the routine compiled and routines that it calls to have a @<*n*> appended to the external symbol name, where n is the number of bytes of all parameters. Both options assume that any routine called from a Fortran routine compiled this way will do its own stack cleanup, "callee pops." `/iface:cvf` also changes the way that `CHARACTER` variables are passed. With `/iface:cvf`, `CHARACTER` variables are passed as address/length pairs (that is, `/iface:mixed_str_len_arg`).

Using Libraries

14

Supplied Libraries

Libraries are simply an indexed collection of object files that are included as needed in a linked program. Combining object files into a library makes it easy to distribute your code without disclosing the source. It also reduces the number of command-line entries needed to compile your project.

Intel® Fortran provides different types of libraries, such as static or DLL, single-threaded or multi-threaded.

On Linux* OS and Mac OS* X systems, you can use the `-shared-intel` compiler option on the command line to specify that you want to use the dynamic versions of all Intel libraries.

The tables below show the libraries provided for the compiler. Except where noted, listed libraries apply to systems based on IA-32 architecture, systems based on Intel® 64 architecture and systems based on IA-64 architecture.

The run-time libraries have associated message catalog files, described in Run-Time Library Message Catalog Location.

The file `fredist.txt` in the `<install-dir> /Documentation` folder lists the Intel compiler libraries that are redistributable.

Table 45: Libraries provided on Windows* OS systems:

File	Description
`ifauto.lib`	Fortran interfaces to Automation objects
`ifcom.lib`	Fortran interfaces to COM support
`ifconsol.lib`	QuickWin stub support
`ifdlg100.dll`	Provides ActiveX* control support to the dialog procedures
`iflogm.lib`	Dialog support
`ifmodintr.lib`	Intrinsic module support
`ifqw_mdi.lib`	QuickWin multi-document support library
`ifqw_sdi.lib`	QuickWin single document support library

File	Description
ifqwin.lib	QuickWin support library
ifwin.lib	Miscellaneous Windows support
libguide.lib	OpenMP* static library for the parallelizer tool
libguide40.lib libguide40.dll	These two libraries make up a dynamic library for the parallelizer tool
libguide_stats.lib	OpenMP static library for the parallelizer tool with performance statistics and profile information
libguide40_stats.lib libguide40_stats.dll	These two libraries make up a dynamic library for the parallelizer tool with performance statistics and profile information
libifcore.lib	Intel-specific Fortran I/O intrinsic support library
libifcoremd.lib libifcoremd.dll	...when compiled with /MD
libifcoremdd.lib libifcoremdd.dll	...when compiled with /MDd
libifcoremt.lib	...when compiled with /MT
libifcorert.lib libifcorert.dll	...when compiled with /MDs
libifcorertd.lib libifcorertd.dll	...when compiled with /MDsd
libifport.lib	Portability, POSIX*, and NLS* support library
libifportmd.dll libifportmd.lib	...when compiled with /MD
libirc.lib	Intel-specific library (optimizations)

File	Description
libircmt.lib	Multithreaded Intel-specific library (optimizations)
libm.lib	Math library
libmmd.lib libmmd.dll	These two libraries make up a dynamic library for the multithreaded math library used when compiling with /MD
libmmdd.lib libmmdd.dll	These two libraries make up a debug dynamic library for the multithreaded math library used when compiling with /MD
libmmds.lib	Static math library built multithread
libmmt.lib	Multithreaded math library used when compiling with /MT
libompstub.lib	Library that resolves references to OpenMP* subroutines when OpenMP is not in use
svml_disp.lib	Short-vector math library (used by vectorizer). Not provided on systems based on IA-64 architecture.
svml_dispmt.lib	Multithread short-vector math library (used by vectorizer). Not provided on systems based on IA-64 architecture.

Table 46: Libraries provided on Linux* OS and Mac OS* X systems:

File	Description
for_main.o	main routine for Fortran programs
libcxaguard.a libcxaguard.so (.dylib for Mac OS X) libcxaguard.so.5 (Linux IA-32 and Intel® 64 architectures) libcxaguard.so.6 (Linux IA-64 architecture)	Used for interoperability with the -cxxlib option.
libguide.a	OpenMP* static library for the parallelizer tool

File	Description
libguide.so (.dylib for Mac OS X)	
libguide_stats.a libguide_stats.so (.dylib for Mac OS X)	Support for parallelizer tool with performance and profile information
libifcore.a libifcore.so (.dylib for Mac OS X) libifcore.so.5 (Linux OS IA-32 and Intel® 64 architectures) libifcore.so.6 (IA-64 architecture)	Intel-specific Fortran run-time library
libifcore_pic.a libifcoremt_pic.a	Intel-specific Fortran static libraries; Linux OS only. These support position independent code and allow creation of shared libraries linked to Intel-specific Fortran *static* run-time libraries, instead of shared run-time libraries.
libifcoremt.a libifcoremt.so (.dylib for Mac OS X) libifcoremt.so.5 (Linux OS IA-32 and Intel® 64 architectures) libifcoremt.so.6 (IA-64 architecture)	Multithreaded Intel-specific Fortran run-time library
libifport.a libifport.so (.dylib for Mac OS X)	Portability and POSIX support

File	Description
`libifport.so.5` (Linux OS IA-32 and Intel® 64 architectures)	
`libifport.so.6` (IA-64 architecture)	
`libifportmt.dylib` (Mac OS X only)	
`libimf.a`	Math library
`libimf.so` (`.dylib` for Mac OS X)	
`libirc.a`	Intel-specific library (optimizations)
`libirc_s.a`	
`libirc.dylib` (Mac OS X)	
`libintlc.so` (`.dylib` for Mac OS X)	Dynamic versions of libirc
`libompstub.a`	Library that resolves references to OMP subroutines when OMP is not in use
`libsvml.a`	Short vector math library
`libsvml.dylib` (Mac OS X)	

Creating Static Libraries

Executables generated using static libraries are no different than executables generated from individual source or object files. Static libraries are not required at runtime, so you do not need to include them when you distribute your executable. At compile time, linking to a static library is generally faster than linking to individual source files.

When compiling a static library from the ifort command line, include the `-c` (Linux OS and Mac OS X) or `/c` (Windows OS) compiler option to suppress linking. Without this option, the compiler generates an error because the library does not contain a main program.

To build a static library (Linux OS):

1. Use the -c option to generate object files from the source files:
   ```
   ifort -c my_source1.f90 my_source2.f90 my_source3.f90
   ```
2. Use the GNU ar tool to create the library file from the object files:
   ```
   ar rc my_lib.a my_source1.o my_source2.o my_source3.o
   ```
3. Compile and link your project with your new library:
   ```
   ifort main.f90 my_lib.a
   ```

If your library file and source files are in different directories, use the `-Ldir` option to indicate where your library is located:

```
ifort -L/for/libs main.f90 my_lib.a
```

To build a static library (Mac OS X):

1. Use the following command line to generate object files and create the library file:
   ```
   ifort -o my_lib.a -staticlib mysource1.f90 mysource2.f90 mysource3.f90
   ```
2. Compile and link your project with your new library:
   ```
   ifort main.f90 my_lib.a
   ```

If your library file and source files are in different directories, use the `-Ldir` option to indicate where your library is located:

```
ifort -L/for/libs main.f90 my_lib.a
```

To build a static library (Windows OS):

To build a static library from the integrated development environment (IDE), select the Fortran Static Library project type.

To build a static library using the command line:

1. Use the /c option to generate object files from the source files:
   ```
   ifort /c my_source1.f90 my_source2.f90
   ```
2. Use the Microsoft LIB tool to create the library file from the object files:
   ```
   lib /out:my_lib.lib my_source1.obj my_source2.obj
   ```
3. Compile and link your project with your new library:
   ```
   ifort main.f90 my_lib.lib
   ```

Creating Shared Libraries

Shared libraries, also referred to as dynamic libraries, are linked differently than static libraries. At compile time, the linker insures that all the necessary symbols are either linked into the executable, or can be linked at runtime from the shared library. Executables compiled from shared libraries are smaller, but the shared libraries must be included with the executable to function correctly. When multiple programs use the same shared library, only one copy of the library is required in memory.

To create a shared library from a Fortran source file, process the files using the ifort command:

- You must specify the `-shared` option (Linux* OS) or the `-dynamiclib` option (Mac OS* X) to create the `.so` or `.dylib` file. On Linux OS and Mac OS X operating systems using either IA-32 architecture or Intel® 64 architecture, you must also specify `-fpic` for the compilation of each object file you want to include in the shared library.
- You can specify the `-o` *`output`* option to name the output file.
- If you omit the `-c` option, you will create a shared library (`.so` file) directly from the command line in a single step.
- If you also omit the `-o` *`output`* option, the file name of the first Fortran file on the command line is used to create the file name of the `.so` file. You can specify additional options associated with shared library creation.
- If you specify the `-c` option, you will create an object file (`.o` file) that you can name with the `-o` option. To create a shared library, process the `.o` file with `ld` , specifying certain options associated with shared library creation.

Creating a Shared Library

There are several ways to create a shared library.

You can create a shared library file with a single ifort command:

```
ifort -shared -fpic octagon.f90 (Linux OS)
ifort -dynamiclib octagon.f90 (Mac OS* X)
```

The `-shared` or `-dynamiclib` option is required to create a shared library. The name of the source file is `octagon.f90`. You can specify multiple source files and object files.

The `-o` option was omitted, so the name of the shared library file is `octagon.so` (Linux OS) or`octagon.dylib` (Mac OS X).

You can use the `-static-intel` option to force the linker to use the static versions of the Intel-supplied libraries.

You can also create a shared library file with a combination of ifort and ld (Linux OS) or libtool (Mac OS X) commands:

First, create the `.o` file, such as `octagon.o` in the following example:

```
ifort -c -fpic octagon.f90
```

The file `octagon.o` is then used as input to the `ld` (Linux OS) or `libtool` (Mac OS X) command to create the shared library. The following example shows the command to create a shared library named `octagon.so` on a Linux operating system:

```
ld -shared octagon.o \
     -lifport -lifcoremt -limf -lm -lcxa \
     -lpthread -lirc -lunwind -lc -lirc_s
```

Note the following:

- When you use `ld`, you need to list all Fortran libraries. It is easier and safer to use the ifort command. On Mac OS X, you would use libtool.
- The `-shared` option is required to create a shared library. On Mac OS X, use the `-dynamiclib` option, and also specify the following: `-arch_only i386`, `-noall_load`, `-weak_references_mismatches non-weak`.
- The name of the object file is `octagon.o`. You can specify multiple object (`.o`) files.
- The `-lifport` option and subsequent options are the standard list of libraries that the ifort command would have otherwise passed to `ld` or `libtool`. When you create a shared library, all symbols must be resolved.

It is probably a good idea to look at the output of the `-dryrun` command to find the names of all the libraries used so you can specify them correctly.

If you are using the `ifort` command to link, you can use the `-Qoption` command to pass options to the ld linker. (You cannot use `-Qoption` on the `ld` command line.)

For more information on relevant compiler options, see the Compiler Options reference.

See also the `ld(1)` reference page.

Shared Library Restrictions

When creating a shared library with `ld`, be aware of the following restrictions:

- Shared libraries must not be linked with archive libraries.

When creating a shared library, you can only depend on other shared libraries for resolving external references. If you need to reference a routine that currently resides in an archive library, either put that routine in a separate shared library or include it in the shared library being created. You can specify multiple object (`.o`) files when creating a shared library.

To put a routine in a separate shared library, obtain the source or object file for that routine, recompile if necessary, and create a separate shared library. You can specify an object file when recompiling with the `ifort` command or when creating the shared library with the `ld` command.

To include a routine in the shared library being created, put the routine (source or object file) with other source files that make up the shared library and recompile if necessary.

Now create the shared library, making sure that you specify the file containing that routine either during recompilation or when creating the shared library. You can specify an object file when recompiling with the `ifort` command or when creating the shared library with the `ld` or libtool command.

- When creating shared libraries, all symbols must be defined (resolved).

  Because all symbols must be defined to `ld` when you create a shared library, you must specify the shared libraries on the `ld` command line, including all standard Intel Fortran libraries. The list of standard Intel Fortran libraries can be specified by using the `-l`*`string`* option.

Installing Shared Libraries

Once the shared library is created, it must be installed for private or system-wide use before you run a program that refers to it:

- To install a *private* shared library (when you are testing, for example), set the environment variable LD_LIBRARY_PATH, as described in ld`(1)`. For Mac OS X, set the environment variable `DYLD_LIBRARY_PATH`.
- To install a *system-wide* shared library, place the shared library file in one of the standard directory paths used by `ld` or `libtool`.

Calling Library Routines

The following table shows the groups of Intel Fortran library routines and the USE statement required to include the interface definitions for the routines in that group:

Routines	USE statement
Portability	USE IFPORT
POSIX*	USE IFPOSIX
Miscellaneous Run-Time	USE IFCORE
The following are Windows only:	
Automation (AUTO) (systems using IA-32 architecture only)	USE IFAUTO
Component Object Model (COM) (systems using IA-32 architecture only)	USE IFCOM
Dialog (systems using IA-32 architecture only)	USE IFLOGM
Graphics	USE IFQWIN
National Language Support	USE IFNLS
QuickWin	USE IFQWIN
Serial port I/O (SPORT)(systems using IA-32 architecture only)	USE IFPORT

Module Routines lists topics that provide an overview of the different groups of library routines as well as calling syntax for the routines. For example, add the following USE statement (before any data declaration statements, such as IMPLICIT NONE or INTEGER):

```
USE IFPORT
```

If you want to minimize compile time for source files that use the Intel Fortran library routines, add the ONLY keyword to the USE statement. For example:

```
USE IFPORT, only: getenv
```

Using the ONLY keyword limits the number of interfaces for that group of library routines.

To view the actual interface definitions, view the `.f90` file that corresponds to the `.mod` file. For example, if a routine requires a USE IFCORE, locate and use a text editor to view the file `ifcore.f90` in the standard INCLUDE directory.

You should avoid copying the actual interface definitions contained in the `ifport.f90` (or `ifcore.f90`, ...) into your program because future versions of Intel Fortran might change these interface definitions.

Similarly, some of the library interface `.f90` files contain USE statements for a subgrouping of routines. However, if you specify a USE statement for such a subgroup, this module name may change in future version of Intel Fortran. Although this will make compilation times faster, it might not be compatible with future versions of Intel Fortran.

Portability Considerations

Portability Library Overview

Intel® Fortran includes functions and subroutines that ease porting of code to or from a PC, or allow you to write code on a PC that is compatible with other platforms.

The portability library is called `LIBIFPORT.LIB` (Windows* OS) or `libifport.a` (Linux* OS and Mac OS* X). Frequently used functions are included in a portability module called IFPORT.

The portability library also contains IEEE* POSIX library functions. These functions are included in a module called IFPOSIX.

You can use the portability library in one of two ways:

- Add the statement USE **IFPORT** to your program. This statement includes the IFPORT module.
- Call portability routines using the correct parameters and return value.

The portability library is passed to the linker by default during linking. To prevent this, specify the `-fpscomp nolibs` (Linux OS and Mac OS X) or `/fpscomp:nolibs` (Windows OS) option.

Using the IFPORT mod file provides interface blocks and parameter definitions for the routines, as well as compiler verification of calls.

See also:

- Using the IFPORT Portability Module
- Portability Routines

Using the IFPORT Portability Module

Using the IFPORT module provides interface blocks and parameter definitions for the portability routines, as well as compiler verification of calls.

Some routines in this library can be called with different sets of arguments, and sometimes even as a function instead of a subroutine. In these cases, the arguments and calling mechanism determine the meaning of the routine. The IFPORT module contains generic interface blocks that give procedure definitions for these routines.

Fortran 95/90 contains intrinsic procedures for many of the portability functions. The portability routines are extensions to the Fortran 95 standard. When writing new code, use Fortran 95/90 intrinsic procedures whenever possible (for portability and performance reasons).

Portability Routines

This section describes some of the portability routines and how to use them.

Refer to the Portability Routines table as you read through this topic.

Information Retrieval Routines

Information retrieval procedures return information about system commands, command-line arguments, environment variables, and process or user information.

Group, user, and process ID are INTEGER(4) variables. Login name and host name are character variables. The functions GETGID and GETUID are provided for portability, but always return 1.

Process Control Routines

Process control routines control the operation of a process or subprocess. You can wait for a subprocess to complete with either SLEEP or ALARM, monitor its progress and send signals via KILL, and stop its execution with ABORT.

In spite of its name, KILL does not necessarily stop execution of a program. Rather, the routine signaled could include a handler routine that examines the signal and takes appropriate action depending on the code passed.

Note that when you use SYSTEM, commands are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The portability library does not include the FORK routine. On Linux* OS and Mac OS* X systems, FORK creates a duplicate image of the parent process. Child and parent processes each have their own copies of resources, and become independent from one another. On Windows* OS systems, you can create a child process (called a thread), but both parent and child processes share the same address space and share system resources.

Numeric Values and Conversion Routines

Numeric values and conversion routines are available for calculating Bessel functions, data type conversion, and generating random numbers. Some of these functions have equivalents in standard Fortran 95/90, in which case the standard Fortran routines should be used.

Data object conversion can be accomplished by using the INT intrinsic function instead of LONG or SHORT. The intrinsic subroutines RANDOM_NUMBER and RANDOM_SEED perform the same functions as the random number functions listed in the table showing numeric values and conversion routines.

Other bit manipulation functions such as AND, XOR, OR, LSHIFT, and RSHIFT are intrinsic functions. You do not need the IFPORT module to access them. Standard Fortran 95/90 includes many bit operation routines, which are listed in the Bit Operation and Representation Routines table.

Input and Output Routines

The portability library contains routines that change file properties, read and write characters and buffers, and change the offset position in a file. These input and output routines can be used with standard Fortran input or output statements such as READ or WRITE on the same files, provided that you take into account the following:

- When used with direct files, after an FSEEK, GETC, or PUTC operation, the record number is the number of the next whole record. Any subsequent normal Fortran I/O to that unit occurs at the next whole record. For example, if you seek to absolute location 1 of a file whose record length is 10, the NEXTREC returned by an INQUIRE would be 2. If you seek to absolute location 10, NEXTREC would still return 2.
- On units with CARRIAGECONTROL='FORTRAN' (the default), PUTC and FPUTC characters are treated as carriage control characters if they appear in column 1.
- On sequentially formatted units, the C string "\n"c, which represents the carriage return/line feed escape sequence, is written as CHAR(13) (carriage return) and CHAR(10) (line feed), instead of just line feed, or CHAR(10). On input, the sequence 13 followed by 10 is returned as just 10. (The length of character string "\n"c is 1 character, whose ASCII value, indicated by ICHAR('\n'c), is 10.)
- Reading and writing is in a raw form for direct files. Separators between records can be read and overwritten. Therefore, be careful if you continue using the file as a direct file.

I/O errors arising from the use of these routines result in an Intel Fortran run-time error.

Some portability file I/O routines have equivalents in standard Fortran 95/90. For example, you could use the ACCESS function to check a file specified by name for accessibility according to mode. It tests a file for read, write, or execute permission, as well as checking to see if the file exists. It works on the file attributes as they exist on disk, not as a program's OPEN statement specifies them.

Instead of ACCESS, you can use the INQUIRE statement with the ACTION specifier to check for similar information. (The ACCESS function always returns 0 for read permission on FAT files, meaning that all files have read permission.)

Date and Time Routines

Various date and time routines are available to determine system time, or convert it to local time, Greenwich Mean Time, arrays of date and time elements, or an ASCII character string.

DATE and TIME are available as either a function or subroutine. Because of the name duplication, if your programs do not include the USE IFPORT statement, each separately compiled program unit can use only one of these versions. For example, if a program calls the subroutine TIME once, it cannot also use TIME as a function.

Standard Fortran 95/90 includes date and time intrinsic subroutines. For more information, see DATE_AND_TIME.

Error Handling Routines

Error handling routines detect and report errors.

IERRNO error codes are analogous to *errno* on Linux* OS and Mac OS* X systems. The IFPORT module provides parameter definitions for many of UNIX's *errno* names, found typically in `errno.h` on UNIX systems.

IERRNO is updated only when an error occurs. For example, if a call to the GETC function results in an error, but two subsequent calls to PUTC succeed, a call to IERRNO returns the error for the GETC call. Examine IERRNO immediately after returning from one of the portability library routines. Other standard Fortran 90 routines might also change the value to an undefined value.

If your application uses multithreading, remember that IERRNO is set on a per-thread basis.

System, Drive, or Directory Control and Inquiry Routines

You can retrieve information about devices, directories, and files with the functions listed below. File names can be long file names or UNC file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications.

Standard Fortran 90 provides the INQUIRE statement, which returns detailed file information either by file name or unit number. Use INQUIRE as an equivalent to FSTAT, LSTAT or STAT. LSTAT and STAT return the same information; STAT is the preferred function.

Serial Port Routines (Windows only)

The serial port I/O (SPORT_*xxx*) routines help you perform basic input and output to serial ports. These routines are available only on systems using IA-32 architecture.

Additional Routines

You can also use portability routines for program call and control, keyboards and speakers, file management, arrays, floating-point inquiry and control, IEEE* functionality, and other miscellaneous uses. See the Portability Routines table.

Math Libraries

Intel® Fortran Compiler includes these math libraries:

Library name	Description
`libimf.a` (Linux* OS and Mac OS* X)	Math libraries provided by Intel. This is in addition to `libm.a`, which is the math library provided with gcc* Both of these libraries are linked in by default because certain math functions supported by the GNU* math library are not available in the Intel math library. This linking arrangement allows the GNU users to have all functions available when using ifort, with Intel optimized versions available when supported. `libimf.a` is linked in before `libm.a`. If you link in `libm.a` first, it will change the versions of the math functions that are used.
`libm.lib` (static library) and `libmmd.dll` (the DLL version) (Windows* OS)	Math Libraries provided by Intel.
Intel® Math Kernel Library (Intel® MKL)	Math library of Fortran routines and functions that perform a wide variety of operations on vectors and matrices. The library also includes fast Fourier transform (fft) functions, as well as vector mathematical and vector statistical functions.

Library name	Description
IMSL* Fortran Numerical Library (Windows* OS)	Libraries provided only with certain editions of the Intel® Visual Fortran product. The IMSL* libraries provide a large collection of mathematical and statistical functions accessible from the visual and command line development environments. .

15 Error Handling

Handling Compile Time Errors

Understanding Errors During the Build Process

The Intel® Fortran Compiler identifies syntax errors and violations of language rules in the source program.

Compiler Diagnostic Messages

These messages describe diagnostics that are reported during the processing of the source file. Compiler diagnostic messages usually provide enough information for you to determine the cause of an error and correct it. These messages generally have the following format:

filename(*linenum*:) *severity*: *message*

filename	Indicates the name of the source file currently being processed.
linenum	Indicates the source line where the compiler detects the condition.
severity	Indicates the severity of the diagnostic message: Warning, Error, or Fatal error.
message	Describes the problem.

The following is an example of an error message showing the format and message text:

```
echar.for(7): Severe: Unclosed DO loop or IF block
       DO I=1,5
--------^
```

The pointer (`---^`) indicates the exact place on the source program line where the error was found, in this case where an **END DO** statement was omitted.

To view the passes as they execute on the command line, specify `-watch` (Linux* OS and Mac OS* X) or `/watch` (Windows* OS).

NOTE. You can perform compile-time procedure interface checking between routines with no explicit interfaces present. To do this, generate a module containing the interface for each compiled routine using the `-gen-interfaces` (Linux OS and Mac OS X) or `/gen-interfaces` (Windows OS) option and check implicit interfaces using the `-warn interfaces` (Linux OS and Mac OS X) or `/warn:interfaces` (Windows OS) option.

Controlling Compiler Diagnostic Warning and Error Messages

You can use a number of compiler options to control the diagnostic messages issued by the compiler. For example, the `-WB` (Linux OS and Mac OS X) or `/WB` (Windows OS) compiler option turns compile time bounds errors into warnings. To control compiler diagnostic messages (such as warning messages), use `-warn` (Linux OS and Mac OS X) or `/warn` (Windows OS). The `-warn [keyword]` (Linux OS and Mac OS X) or `/warn:keyword` (Windows OS) option controls warnings issued by the compiler and supports a wide range of values. Some of these are as follows:

[no]alignments -- Determines whether warnings occur for data that is not naturally aligned.

[no]declarations -- Determines whether warnings occur for any undeclared symbols.

[no]errors -- Determines whether warnings are changed to errors.

[no]general -- Determines whether warning messages and informational messages are issued by the compiler.

[no]interfaces -- Determines whether warnings about the interfaces for all called SUBROUTINEs and invoked FUNCTIONs are issued by the compiler.

[no]stderrors -- Determines whether warnings about Fortran standard violations are changed to errors.

[no]truncated_source -- Determines whether warnings occur when source exceeds the maximum column width in fixed-format files.

For more information, see the `-warn` compiler option.

You can also control the display of diagnostic information with variations of the `-diag` (Linux OS and Mac OS X) or `/Qdiag` (Windows OS) compiler option. This compiler option accepts numerous arguments and values, allowing you wide control over displayed diagnostic messages and reports.

Some of the most common variations include the following:

Linux OS and Mac OS X	Windows OS	Description
`-diag-enable` *`list`*	`/Qdiag-enable:`*`list`*	Enables a diagnostic message or a group of messages
`-diag-disable` *`list`*	`/Qdiag-disable:`*`list`*	Disables a diagnostic message or a group of messages
`-diag-warning` *`list`*	`/Qdiag-warning:`*`list`*	Tells the compiler to change diagnostics to warnings
`-diag-erro` *`list`*	`/Qdiag-error:`*`list`*	Tells the compiler to change diagnostics to errors
`-diag-remark` *`list`*	`/Qdiag-remark:`*`list`*	Tells the compiler to change diagnostics to remarks (comments)

The *`list`* items can be specific diagnostic IDs, one of the keywords `warn`, `remark`, or `error`, or a keyword specifying a certain group (`par`, `vec`, `driver`, `cpu-dispatch`, `sv`). For more information, see `-diag`, `/Qdiag`.

Additionally, you can use the following related options:

Linux OS and Mac OS X	Windows OS	Description
`-diag-dump`	`/Qdiag-dump`	Tells the compiler to print all enabled diagnostic messages and stop compilation
`-diag-file[=`*`file`*`]`	`/Qdiag-file[:`*`file`*`]`	Causes the results of diagnostic analysis to be output to a file
`-diag-file-append[=`*`file`*`]`	`/Qdiag-file-append[:`*`file`*`]`	Causes the results of diagnostic analysis to be appended to a file
`-diag-error-limit n`	`/Qdiag-error-limit:n`	Specifies the maximum number of errors allowed before compilation stops.

Linker Diagnostic Errors

If the linker detects any errors while linking object modules, it displays messages about their cause and severity. If any errors occur, the linker does not produce an executable file. Linker messages are descriptive, and you do not normally need additional information to determine the specific error.

To view the libraries being passed to the linker on the command line, specify `-watch` or `/watch`.

Error Severity Levels

Comment Messages

These messages indicate valid but inadvisable use of the language being compiled. The compiler displays comments by default. You can suppress comment messages with the `-warn nousage` (Linux OS and Mac OS X) or `/warn:nousage` (Windows OS) option.

Comment messages do not terminate translation or linking, they do not interfere with any output files either. Some examples of the comment messages are:

```
Null CASE construct
The use of a non-integer DO loop variable or expression
Terminating a DO loop with a statement other than CONTINUE or ENDDO
```

Warning Messages

These messages report valid but questionable use of the language being compiled. The compiler displays warnings by default. You can suppress warning messages by using the `-warn` or `/warn` option. Warnings do not stop translation or linking. Warnings do not interfere with any output files. Some representative warning messages are:

```
constant truncated - precision too great
non-blank characters beyond column 72 ignored
Hollerith size exceeds that required by the context
```

Error Messages

These messages report syntactic or semantic misuse of Fortran.

Errors suppress object code for the error containing the error and prevent linking, but they do not stop from parsing to continue to scan for any other errors. Some typical examples of error messages are:

```
line exceeds 132 characters
unbalanced parenthesis
incomplete string
```

Fatal Errors

Fatal messages indicate environmental problems. Fatal error conditions stop translation, assembly, and linking. If a fatal error ends compilation, the compiler displays a termination message on standard error output. Some representative fatal error messages are:

```
Disk is full, no space to write object file
Incorrect number of intrinsic arguments
Too many segments, object format cannot support this many segments
```

Using the Command Line

If you are using the command line, messages are written to the standard error output file.

When using the command line:

- Make sure that the appropriate environment variables have been set by executing the `ifortvars.sh` (Linux OS and Mac OS X) or`IFORTVARS.BAT` (Windows OS) file. For example, this BAT file sets the environment variables for the include and library directory paths. For Windows OS, these environment variables are preset if you use the Fortran Command Prompt window in the Intel® Visual Fortran program folder. For a list of environment variables used by the ifort command during compilation, see Setting Compile-Time Environment Variables.
- Specify the libraries to be linked against using compiler options.
- You can specify libraries (include the path, if needed) as file names on the command line.

Compiler Message Catalog Support

Intel Fortran provides a message catalog that contains various compile-time diagnostic messages.

Use the NLSPATH or %PATH% (Windows OS) environment variable to specify the location of the compiler message catalog. Note that this environment variable, which can be defined to point to multiple paths, is also used to specify the location of the run-time catalog. For more information on run-time library catalogs, see Run-Time Message Display and Format.

Using Source Code Verification

Source Checker Overview

The Intel® Fortran Compiler Professional product provides the following source code analysis features:

- source checker analysis
- parallel lint

Source Checker

The source checker is a compiler feature that provides advanced diagnostics based on detailed analysis of source code. It performs static global analysis to find errors in software that go undetected by the compiler itself. general source code analysis tool that provides an additional diagnostic capability to help you debug your programs. You can use source code analysis options to detect potential errors in your compiled code including:

- incorrect usage of OpenMP* directives
- inconsistent object declarations in different program units
- boundary violations
- uninitialized memory
- memory corruptions
- memory leaks
- incorrect usage of pointers and allocatable arrays
- dead code and redundant executions
- typographical errors or uninitialized variables
- dangerous usage of unchecked input

The source checker can be used to analyze and find issues with source files; these source files need not form a whole program (for instance, you can check a library source). In such cases, due to the lack of full information on usage and modification of global objects, calls to routines, and so forth, analysis will be less exact.

Your code must successfully compile, with no errors, for source code analysis options to take effect.

The intended output from the source checker are useful diagnostics; no executable is generated. Object files and library files generated during source checker analysis cannot be used to generate an executable or a dynamic or static library.

Source checker analysis performs a general overview check of a program for all possible values simultaneously. This is in contrast to run-time checking tools that execute a program with a fixed set of values for input variables; such checking tools cannot easily check all edge effects. By not using a fixed set of input values, the source checker analysis can check for all possible corner cases.

Limitations of Source Checker Analysis

Since the source checker does not perform full interpretation of analyzed programs, it can generate so called false-positive messages. This is a fundamental difference between the compiler and source checker generated errors; in the case of the source checker, you decide whether the generated error is legitimate and needs to be fixed.

Example 1: Incorrect message about division by 0

In this example, possible values for parameter x are {6,3}, for parameter y are {3,0}. If x and y both have the value 3, the expression x-y is equal to 0. The source checker cannot identify that the value 3 for x and y cannot coexist.

```
1 #include <stdio.h>
2
3 double foo(int x, int y) {
4 return 1 / (x - y);
5 }
6
7 int main() {
8 printf("%f\n", foo(6, 3));
9 printf("%f\n", foo(3, 0));
10 return 0;
11 }
```

The source checker issues the following message:

```
f1.c(4): error #12062: possible division by 0
```

Example 2: Incorrect message about uninitialization

This example illustrates how a false positive can appear from conditional statements.

```
1 #include <stdio.h>
2
3 int main(int n) {
4 int j;
5 if (n != 0) {
6 j = n;
7 }
8 if (n != 0) {
 9 printf("%d\n", j);
10 }
11 return 0;
12 }
```

The source checker issues the following message:

```
f1.c(9): error #12144: "j" is possibly uninitialized
```

Parallel Lint

Writing and debugging parallel programs requires specific knowledge and tools. Parallel lint can help in both the development of parallel applications and the parallelizing of existing serial applications. Based on source checker algorithms, parallel lint is a source code analysis capability that performs parallelization analysis of OpenMP* programs. The OpenMP 3.0 standard is supported. OpenMP provides a variety of ways for expressing parallelization. Parallel lint can diagnose problems with OpenMP directives and clauses, including:

- nested parallel regions including dynamic extent of parallel regions
- private/shared/reduction variables in parallel regions
- threadprivate variables
- expressions used in OpenMP clauses

In certain cases, an OpenMP program can meet all requirements of the specification but still have serious semantic issues. Parallel lint can help diagnose:

- some types of deadlocks

- data races or potential data dependency
- side effects without proper synchronization

Parallel lint also performs interprocedural analysis and can find issues with parallel directives located in different procedures or files.

Using the Source Code Analysis Options

Source code analysis options include the following:

Option	Result
`-diag-enable sc{[1|2|3]}` (Linux* OS and Mac OS* X) `/Qdiag-enable:sc{[1|2|3]}` (Windows* OS)	Enables source checker analysis. The number specifies the several level of the diagnostics (1=all critical errors, 2=all errors, and 3=all errors and warnings)
`-diag-disable sc` `/Qdiag-disable:sc`	Disables source checker analysis
`-diag-enable sc-parallel{[1|2|3]}` `/Qdiag-enable:sc-parallel{[1|2|3]}`	Enables parallel lint analysis. The number specifies the several level of the diagnostics (1=all critical errors, 2=all errors, and 3=all errors and warnings)
`-diag-disable sc-parallel` `/Qdiag-disable:sc-parallel`	Disables parallel lint analysis
`-diag-enable sc-include` `/Qdiag-enable:sc-include`	Analyzes include files as well as source files.
`-diag-disable warn` `/Qdiag-disable:warn`	Suppresses all warnings, cautions and comments (issues errors only), including those specific to source code analysis

Option	Result
`-diag-disable num-list` `/Qdiag-disable:num-list`	Suppresses messages by number list, where *num-list* is either a single message or a list of message numbers separated by commas and enclosed in parentheses
`-diag-file [file]` `/Qdiag-file[:file]`	Directs diagnostic results to file with `.diag` as the default extension. You need to enable source code analysis diagnostics before you can send them to a file. If a file name is not specified, the diagnostics are sent to *name-of-the-first-source-file*`.diag`.
`-diag-file-append[=file]` `/Qdiag-file-append[:file]`	Appends diagnostic results to file with `.diag` as the default extension. You need to enable source code analysis diagnostics before you can send the results to a file. If you do not specify a path, the current working directory will be searched. If the named file is not found, a new file with that name will be created. If a file name is not specified, the diagnostics are sent to *name-of-the-first-source-file*`.diag`.

The following notes apply:

- Parallel lint diagnostics are a subset of source checker diagnostics. If both the source checker and parallel lint options are specified, only source checker options are used.
- When using parallel lint, be sure to specify the OpenMP compiler option. Add the `-openmp` (Linux OS and Mac OS X) or `/Qopenmp` (Windows OS) option to the command line.
- Specify the `-diag-enable sc-include` (Linux OS and Mac OS X) or `/Qdiag-enable:sc-include` (Windows OS) option to analyze both source files and include files.

Using Source Code Analysis Options with Other Compiler Options

If the `-c` (Linux OS and Mac OS X) or `/c` (Windows OS) compiler option is used on the command line along with a command line option to enable source code analysis, an object file is created; source code analysis diagnostics are not produced. This object file may be used in

a further invocation of source code analysis. To receive complete source code diagnostics, specify source code analysis options for both compilation and linking phases. This feature is useful when a program consists of files written in different languages (C/C++ and Fortran).

```
icc -c -diag-enable sc2 file1.c

ifort -c -diag-enable sc2 file2.f90

icc -diag-enable sc2 file1.obj file2.obj
```

To analyze OpenMP directives, add the `-openmp` (Linux OS and Mac OS X) or `/Qopenmp` (Windows OS) option to the command line.

Using Source Code Analysis within the IDE

When source code analysis support is enabled within the IDE, the customary final build target (e.g. an executable image) is not created. Therefore, you should create a separate "Source Code Analysis" configuration.

In the Eclipse* IDE, do the following:

1. Open the property pages for the project and select **C/C++ Build** .
2. Click the **Manage...** button.
3. In the **Manage** dialog box, click the **New...** button to open the **Create configuration** dialog box.
4. Supply a name for the new configuration in the **Name** box; for example, **Source Code Analysis**.
5. Supply a **Description** for the configuration if you want (optional).
6. You can choose to **Copy settings from** a **Default configuration** or an **Existing configuration** by clicking the appropriate radio button and then selecting a configuration from the corresponding drop down menu.
7. Click **OK** to close the **Create configuration** dialog box.
8. Click **OK** to close the **Manage** dialog box (with your new configuration name selected).

The property pages will now display the settings for your new configuration; this becomes the active build configuration. Navigate to the Intel compiler's **Compilation Diagnostics** properties. Use the **Level of Source Code Parallelization Analysis**, **Level of Source Code Analysis**, and **Analyze Include Files** properties to control source code analysis.

Source Checker Capabilities

Source checker analysis capabilities include the following:

- Interprocedural Analysis for detecting inconsistent objects declarations in different program units and for propagation of data (for example, pointer aliases and argument constant values) using procedure calls
- Local Program Analysis for analyzing each program unit separately and checking for various kinds of problems that will errors or warnings.
- C/C++ specific Analysis for analyzing C/C++ source code and checking for C/C++ specific error and warning conditions. Source code analysis also detects improper code style and flaws in object-oriented design solutions.
- Fortran-specific Analysis for analyzing Fortran source code and checking for Fortran-specific error and warning conditions.
- OpenMP* Analysis for checking for OpenMP API restrictions.

Interprocedural Analysis

Source code analysis detects inconsistent object declarations in different program units, for example:

- Different external objects with the same name.
- Inconsistent declarations of a COMMON block (Fortran-specific).
- Mismatched number of arguments.
- Mismatched type, rank, shape, or/and size of an argument.
- Inconsistent declaration of a procedure.

The following examples illustrate interprocedural analysis.

Example 1: Wrong number of arguments

File f1.c contains this function declaration:

```
1  void Do_hello() {
2      printf("helo everybody!\n");
}
```

File f2.c contains a call to the routine:

```
1 extern void Do_hello(int);

2

3 void foo() {

4 Do_hello ( 1 ) ;

 5 }
```

The source checker issues the following message:

```
f2.c(4): error #12020: number of actual arguments (1) in call of "Do_hello"
doesn't match the number of formal arguments (0); "Do_hello" is defined at
(file:f1.c line:1)
```

The other goal of interprocedural analysis is to propagate information about program objects across the program through procedure calls. The following information is propagated :

- Ranges of constant values
- Pointer attributes
- Information about usage and modification of objects

Example 2: Out of Boundaries

This example demonstrates the propagation of pointer A to Arr and the constant value 5 to x:

```
1 void foo( int* Arr, int x) {

2 for(; 0<=x; x--) {

3 Arr[x] = x;

4 }

5 }

6

7 void bar() {

8 int A[5];

9 foo(A,5);

10 }
```

The source checker issues the following message:

```
f1.c(3): error #12255: Buffer overflow: index is possibly outside the bounds
for array "A" which is passed as actual argument 1 to "foo" at (file:f2.c
line:9); array "A" of size (0:4) can be indexed by value 5
```

Local Program Analysis

The source checker uses local analysis of each program unit to check for various kinds of errors, warnings, and/or debatable points in a program. Examples of these errors are:

- Incorrect use or modification of an object
- Problems with memory (for example, leaks, corruptions, uninitialized memory)
- Incorrect use with pointers
- Boundaries violations
- Wrong value of an argument in an intrinsic call
- Dead code and redundant executions

The following examples illustrate local program analysis.

Example 1: Object is smaller than required size

```
1 #include <stdio.h>
2 #include <string.h>
3
4 int main(void){
5 char string[10];
6
7 strcpy(string, "Hello world from");
8 printf("%s\n",string);
9
10 return 0;
11 }
```

The following message is issued :

```
f1.c(7): error #12224: Buffer overflow: size of object "string" (10 bytes)
is less than required size (17 bytes)
```

Example 2: Memory Leak

File `f1.c` contains the following:

```
1 #include <stdio.h>
2 #include <malloc.h>
3
4 int main(void) {
5 float **ptr;
6
7 ptr = (float **)malloc(8);
8 if (ptr == NULL) exit(1);
9 *ptr = (float*)malloc(sizeof(float));
10 if (*ptr == NULL) exit(1);
11 **ptr = 3.14;
12 printf("%f\n",**ptr);
13 free(ptr);
14 return 0;
15 }
```

The source checker issues the following message:

```
f1.c(14): error #12121: memory leak: dynamic memory allocated at (file:f1.c
line:9) is not freed at this point
```

Fortran-specific Analysis

The source checker is able to detect issues with the following:

- Mismatched type, rank, shape, or/and size of an argument
- Incorrect usage of ALLOCATABLE arrays
- Inconsistency in COMMON blocks

The following example illustrates Fortran-specific analysis.

Example 1: Undefined function result

File f1.f contains the following lines:

```
1 subroutine foo(m)
2 integer, dimension(2,3) :: m
```

```
3 do i=1,3
4 print *,m(:,i)
5 end do
6 end
7 integer, dimension(3,2) :: n
8 do i=1,2
9 n(:,i) = i
10 end do
11 call foo(n)
12 ! shapes of argument #1 and dummy argument are different.
13 do i=1,2
14 print *,n(:,i)
15 end do
16 end
```

Source code analysis issues the following message:

```
f1.f(11): error #12028: shape of actual argument 1 in call of "FOO" doesn't
match the shape of formal argument "M"; "FOO" is defined
```

C/C++ specific Analysis

Source code analysis examines C/C++ source code and checks for C++ specific errors. It also points out places of improper code style and flaws in object-oriented design solutions.

The source checker detects issues with the following:

- Memory management (leaks, mixing C and C++ memory management routines, smart pointer usage)
- C++ exception handling (uncaught exception, exception from destructor/operator delete)
- Misuse of operator new/operator delete
- Misuse of virtual functions

Example 1: Call of virtual function from constructor

```
1 #include "stdio.h"
2
3 class A {
4 public:
5 A() { destroy(); }
6 void destroy() { clear0();}
7 virtual void clear()=0;
8 void clear0() { clear(); };
9 };
10
11 class B : public A {
12 public:
13 B(){ }
14 virtual void clear(){ printf("overloaded clear"); }
15 virtual ~B() { }
16 };
17
18 int main() {
19 B b;
20 return 0;
21 }
```

The source checker issues the following message:

```
f1.cpp(8): warning #12327: pure virtual function "clear" is called from
constructor (file:f1.cpp line:5)
```

OpenMP* Analysis

The compiler detects some restrictions noted in the OpenMP* API. With OpenMP analysis, additional checks for misuse of the OpenMP API are performed.

Example 1: Incorrect usage of OpenMP directives

File f1.c contains the following lines:

```
1 #include <stdio.h>
2 #include <omp.h>
3
4 void fff(int ii) {
5 #pragma omp barrier
6 printf("Val = %d \n", ii);
7 }
8
9 int main(void) {
10 int i=3;
11 omp_set_num_threads(3);
12 #pragma omp parallel
13 #pragma omp master
14 fff(i);
15 return 0;
16 }
```

Source code analysis issues the following message:

```
f1.c(5): error #12200: BARRIER directive is not allowed in the dynamic extent
of MASTER directive (file:f1.c line:13)
```

Example 2: Incorrect data dependency

To enable data dependency analysis for a parallel program, enable diagnostics at level 3 .

```
1 int main(void) {
2 int i,sum = 0;
3 int a[1000];
4
5 #pragma omp parallel for reduction(+:sum)
6 for (i=1; i<999; i++) {
7 a[i] = i;
8 sum = sum + a[i + 1];
9 }
10 }
```

Source code analysis issues the following message:

```
f1.c(8): warning #12247: anti data dependence from (file:f1.c line:8) to
(file:f1.c line:7), due to "a" may lead to incorrect program execution in
parallel mode
```

Example 3: Incorrect synchronization

File f1.c contains the following lines:

```
1 #include <stdio.h>
2 #include <omp.h>
3
4 int a[1000];
5 int sum = 0;
6
7 void moo() {
8 int i;
9
10 #pragma omp task
11 for (i=0; i<1000; i++) {
12 a[i] = i;
13 sum = sum + a[i];
14 }

15 }

16

17 void foo() {

18 printf("%d\n",sum);

19 }

20

21 int main(void) {

22 int i;
```

```
23

24 #pragma omp parallel shared(sum)

25 #pragma omp single

26 {

27 moo();

28 foo();

29 }

30 return 0;

31 }
```

Source code analysis issues the following message:

```
f1.c(18): error #12365: variable "sum" is defined at (file:f1.c line:13) in
TASK region (file:f1.c line:10) and is used before synchronization
```

Handling Run-Time Errors

Understanding Run-Time Errors

During execution, your program may encounter errors or exception conditions. These conditions can result from any of the following:

- Errors that occur during I/O operations
- Invalid input data
- Argument errors in calls to the mathematical library
- Arithmetic errors
- Other system-detected errors

The Intel® Fortran run-time system (Run-Time Library or RTL) generates appropriate messages and takes action to recover from errors whenever possible.

For a description of each Intel Fortran run-time error message, see List of Run-Time Error Messages.

There are a few tools and aids that are helpful when an application fails and you need to diagnose the error. Compiler-generated machine code listings and linker-generated map files can help you understand the effects of compiler optimizations and to see how your application is laid out in memory. They may help you interpret the information provided in a stack trace at the time of the error. See Generating Listing and Map Files.

Forcing a Core Dump for Severe Errors

You can force a core dump for severe errors that do not usually cause a `core` file to be created. Before running the program, set the `DECFORT_DUMP_FLAG` environment variable to any of the common TRUE values (Y, y, Yes, yEs, True, and so forth) to cause severe errors to create a `core` file. For instance, the following C shell command sets the `DECFORT_DUMP_FLAG` environment variable:

```
setenv decfort_dump_flag y
```

The `core` file is written to the current directory and can be examined using a debugger.

NOTE. If you requested a core file to be created on severe errors and you don't get one when expected, the problem might be that your process limit for the allowable size of a core file is set too low (or to zero). See the man page for your shell for information on setting process limits. For example, the C shell command limit (with no arguments) will report your current settings, and `limit coredumpsize unlimited` will raise the allowable limit to your current system maximum.

Run-Time Default Error Processing

The Intel® Fortran run-time system processes a number of errors that can occur during program execution. A default action is defined for each error recognized by the Intel Fortran run-time system. The default actions described throughout this section occur unless overridden by explicit error-processing methods.

The way in which the Intel Fortran run-time system actually processes errors depends upon the following factors:

- The severity of the error. For instance, the program usually continues executing when an error message with a severity level of warning or info (informational) is detected.
- For certain errors associated with I/O statements, whether or not an I/O error-handling specifier was specified.
- For certain errors, whether or not the default action of an associated signal was changed.
- For certain errors related to arithmetic operations (including floating-point exceptions), compilation options can determine whether the error is reported and the severity of the reported error.

How arithmetic exception conditions are reported and handled depends on the cause of the exception and how the program was compiled. Unless the program was compiled to handle exceptions, the exception might not be reported until *after* the instruction that caused the exception condition.

Run-Time Message Display and Format

Fortran run-time messages have the following format:

forrtl: *severity* (*number*): *message-text*

where:

- *forrtl*

Identifies the source as the Intel Fortran run-time system (Run-Time Library or RTL).

- *severity*

  The severity levels are: *severe.info* , or *warning*,*error* ,

- *number*

  This is the message number; also the IOSTAT value for I/O statements.

- *message-text*

  Explains the event that caused the message.

The following table explains the severity levels of run-time messages, in the order of greatest to least severity. The severity of the run-time error message determines whether program execution continues:

Severity	Description
severe	Must be corrected. The program's execution is terminated when the error is encountered unless the program's I/O statements use the END, EOR, or ERR branch specifiers to transfer control, perhaps to a routine that uses the IOSTAT specifier. (See Using the END, EOR, and ERR Branch Specifiers and Using the IOSTAT Specifier and Fortran Exit Codes and Methods of Handling Errors.) For severe errors, stack trace information is produced by default, unless the environment variable FOR_DISABLE_STACK_TRACE is set. If the command line option -traceback (Linux* OS and Mac OS* X) or /traceback (Windows* OS) is specified, the stack trace information contains program counters set to symbolic information. Otherwise, the information contains merely hexadecimal program counter information. In some cases stack trace information is also produced by the compiled code at run-time to provide details about the creation of array temporaries. If FOR_DISABLE_STACK_TRACE is set, no stack trace information is produced.
error	Should be corrected. The program might continue execution, but the output from this execution might be incorrect. For errors of severity type error, stack trace information is produced by default, unless the environment variable FOR_DISABLE_STACK_TRACE is set. If the command line option -traceback (Linux OS and Mac OS X) or /traceback (Windows) is specified, the stack trace information contains program counters set to symbolic information. Otherwise, the information contains merely hexadecimal program counter information. In some cases stack trace information is also produced by the compiled code at run-time to provide details about the creation of array temporaries.

Severity	Description
	If FOR_DISABLE_STACK_TRACE is set, no stack trace information is produced.
warning	Should be investigated. The program continues execution, but output from this execution might be incorrect.
info	For informational purposes only; the program continues.

For a description of each Intel Fortran run-time error message, see Run-Time Default Error Processing and related topics.

The following example applies to Linux OS and Mac OS X:

In some cases, stack trace information is produced by the compiled code at run time to provide details about the creation of array temporaries.

(If FOR_DISABLE_STACK_TRACE is set, no stack trace information is produced.)

The following program generates an error at line 12:

```
program ovf
real*4 x(5),y(5)
integer*4 i

x(1) = -1e32
x(2) = 1e38
x(3) = 1e38
x(4) = 1e38
x(5) = -36.0

do i=1,5
y(i) = 100.0*(x(i))
print *, 'x = ', x(i), ' x*100.0 = ',y(i)
end do
end
```

The following command line produces stack trace information for the program executable.

```
> ifort -O0 -fpe0 -traceback ovf.f90 -o ovf.exe
> ovf.exe

x =  -1.0000000E+32  x*100.0
 =  -1.0000000E+34
forrtl: error (72): floating overflow
Image        PC         Routine       Line      Source
ovf.exe      08049E4A   MAIN__            14    ovf.f90
ovf.exe      08049F08   Unknown       Unknown   Unknown
ovf.exe      400B3507   Unknown       Unknown   Unknown
ovf.exe      08049C51   Unknown       Unknown   Unknown
Abort
```

The following suppresses stack trace information because the FOR_DISABLE_STACK_TRACE environment variable is set.

```
> setenv FOR_DISABLE_STACK_TRACE true
> ovf.exe

x =  -1.0000000E+32  x*100.0 =  -1.0000000E+34
forrtl: error (72): floating overflow
Abort
```

Run-Time Library Message Catalog File Location

The libifcore, libirc, and libm run-time libraries ship message catalogs. When a message by one of these libraries is to be displayed, the library searches for its message catalog in a directory specified by either the `NLSPATH` (Linux OS and Mac OS X), or `%PATH%` (Windows OS) environment variable. If the message catalog cannot be found, the message is displayed in English.

The names of the three message catalogs are as follows:

libifcore message catalogs and related text message files	Linux OS and Mac OS X	ifcore_msg.cat ifcore_msg.msg
	Windows OS	ifcore_msg.dll ifcore_msg.mc
libirc message catalogs and related text message files	Linux OS and Mac OS X	irc_msg.cat irc_msg.msg
	Windows OS	irc_msg.dll irc_msg.mc
libm message catalogs and related text message files	Linux OS and Mac OS X	libm.cat libm.msg
	Windows OS	libmUI.dll libmUI.mc

Values Returned at Program Termination

An Intel Fortran program can terminate in a number of ways. On Linux OS and Mac OS X, values are returned to the shell.

- The program runs to normal completion. A value of zero is returned.
- The program stops with a `STOP` statement. If an integer stop-code is specified, a status equal to the code is returned; if no stop-code is specified, a status of zero is returned.
- The program stops because of a signal that is caught but does not allow the program to continue. A value of 1 is returned.
- The program stops because of a severe run-time error. The error number for that run-time error is returned. See Understanding Run-Time Errors and related topics.
- The program stops with a **`CALL EXIT`** statement. The value passed to **`EXIT`** is returned.
- The program stops with a `CALL ABORT` statement. A value of 134 is returned.

Methods of Handling Errors

Whenever possible, the Intel® Fortran RTL does certain error handling, such as generating appropriate messages and taking necessary action to recover from errors. You can explicitly supplement or override default actions by using the following methods:

- To transfer control to error-handling code within the program, use the END, EOR, and ERR branch specifiers in I/O statements. See Using the END, EOR, and ERR Branch Specifiers.
- To identify Fortran-specific I/O errors based on the value of Intel Fortran RTL error codes, use the I/O status specifier (IOSTAT) in I/O statements (or call the `ERRSNS` subroutine). See Using the IOSTAT Specifier and Fortran Exit Codes.
- Obtain system-level error codes by using the appropriate library routines.
- For certain error conditions, use the signal handling facility to change the default action to be taken.

Using the END, EOR, and ERR Branch Specifiers

When a severe error occurs during Intel® Fortran program execution, the default action is to display an error message and terminate the program. To override this default action, there are three branch specifiers you can use in I/O statements to transfer control to a specified point in the program:

- The END branch specifier handles an end-of-file condition.
- The EOR branch specifier handles an end-of-record condition for nonadvancing reads.
- The ERR branch specifier handles all error conditions.

If you use the END, EOR, or ERR branch specifiers, no error message is displayed and execution continues at the designated statement, usually an error-handling routine.

You might encounter an unexpected error that the error-handling routine cannot handle. In this case, do one of the following:

- Modify the error-handling routine to display the error message number.
- Remove the END, EOR, or ERR branch specifiers from the I/O statement that causes the error.

After you modify the source code, compile, link, and run the program to display the error message. For example:

```
READ (8,50,ERR=400)
```

If any severe error occurs during execution of this statement, the Intel Visual Fortran RTL transfers control to the statement at label 400. Similarly, you can use the END specifier to handle an end-of-file condition that might otherwise be treated as an error. For example:

```
READ (12,70,END=550)
```

When using nonadvancing I/O, use the EOR specifier to handle the end-of-record condition. For example:

```
150 FORMAT (F10.2, F10.2, I6)
    READ (UNIT=20, FMT=150, SIZE=X, ADVANCE='NO', EOR=700) A, F, I
```

You can also use ERR as a specifier in an OPEN, CLOSE, or INQUIRE statement. For example:

```
OPEN (UNIT=10, FILE='FILNAM', STATUS='OLD', ERR=999)
```

If an error is detected during execution of this `OPEN` statement, control transfers to the statement at label 999.

Using the IOSTAT Specifier and Fortran Exit Codes

You can use the IOSTAT specifier to continue program execution after an I/O error and to return information about I/O operations. Certain errors are *not* returned in IOSTAT.

The IOSTAT specifier can supplement or replace the END, EOR, and ERR branch transfers.

Execution of an I/O statement containing the IOSTAT specifier suppresses the display of an error message and defines the specified integer variable, array element, or scalar field reference as one of the following, which is returned as an exit code if the program terminates:

- A value of -2 if an end-of-record condition occurs with nonadvancing reads.
- A value of -1 if an end-of-file condition occurs.
- A value of 0 for normal completion (not an error condition, end-of-file, or end-of-record condition).
- A positive integer value if an error condition occurs. (This value is one of the Fortran-specific IOSTAT numbers listed in the run-time error message. See List of Run-Time Error Messages, which lists the messages.)

Following the execution of the I/O statement and assignment of an IOSTAT value, control transfers to the END, EOR, or ERR statement label, if any. If there is no control transfer, normal execution continues.

You can include the `for_iosdef.for` file in your program to obtain symbolic definitions for the values of IOSTAT.

The following example uses the IOSTAT specifier and the `for_iosdef.for` file to handle an `OPEN` statement error (in the FILE specifier).

Error Handling OPEN Statement File Name

```
     CHARACTER(LEN=40) :: FILNM
    INCLUDE 'for_iosdef.for'
    DO I=1,4      FILNM = ''
      WRITE (6,*)  'Type file name '
      READ (5,*) FILNM
      OPEN (UNIT=1, FILE=FILNM, STATUS='OLD', IOSTAT=IERR, ERR=100)
      WRITE (6,*) 'Opening file: ', FILNM
!       (process the input file)
      CLOSE (UNIT=1)
      STOP
  100  IF (IERR .EQ. FOR$IOS_FILNOTFOU) THEN
        WRITE (6,*) 'File: ', FILNM, ' does not exist '
      ELSE IF (IERR .EQ. FOR$IOS_FILNAMSPE) THEN
         WRITE (6,*) 'File: ', FILNM, ' was bad, enter new file name'
      ELSE
        PRINT *, 'Unrecoverable error, code =', IERR
        STOP
      END IF
    END DO
    WRITE (6,*) 'File not found. Locate correct file with Explorer and run again'
  END PROGRAM
```

Another way to obtain information about an error is the ERRSNS subroutine, which allows you to obtain the last I/O system error code associated with an Intel Fortran RTL error (see the *Intel® Fortran Language Reference*).

Locating Run-Time Errors

This topic provides some guidelines for locating the cause of exceptions and run-time errors. Intel Fortran run-time error messages do not usually indicate the exact source location causing the error. The following compiler options are related to handling errors and exceptions:

- The `-check [keyword]` (Linux OS Mac OS X) or `/check[:keyword]` (Windows OS) option generates extra code to catch certain conditions at run time. For example, if you specify the keyword of `bounds`, the debugger will catch and stop at array or character string bounds errors. You can specify the keyword of `bounds` to generate code to perform compile-time and run-time checks on array subscript and character substring expressions. An error is

reported if the expression is outside the dimension of the array or the length of the string. The keyword of `uninit` generates code for dynamic checks of uninitialized variables. If a variable is read before written, a run-time error routine will be called. The `noformat` and `nooutput_conversion` keywords reduce the severity level of the associated run-time error to allow program continuation. The `pointers` keyword generates code to test for disassociated pointers and unallocatable arrays.

The following `-check pointers` (Linux OS and Mac OS X) or `/check:pointers` (Windows OS) examples result in various output messages.

Example 1: Allocatable variable not allocated

```
        real, allocatable:: a(:)
!       allocate(a(4))  ! if a is unallocated, the next statement gets an error with
"check pointers"
        a=17
        print  *,a
        end
 Output 1:
forrtl: severe (408): fort: (8): Attempt to fetch from allocatable variable A when it
is not allocated
```

Example 2: Pointer not associated

```
        real, pointer:: a(:)
        allocate(a(5))
        a=17
        print  *,a
        deallocate(a)   ! once a is deallocated, the next statement gets an error with
"check pointers"
        a=20
        print  *,a
        end

Output 2:
   17.00000       17.00000       17.00000       17.00000       17.00000
forrtl: severe (408): fort: (7): Attempt to use pointer A when it is not associated with
 a target
```

Example 3: Cray pointer with zero value

```
        pointer(p,a)
        real, target:: b
!       p=loc(b)        ! if integer pointer p has no address assigned to it,
!                       ! the next statement gets an error with "check pointers"
        b=17.
        print  *,a
        end

Output 3:
forrtl: severe (408): fort: (9): Attempt to use pointee A when its corresponding integer
 pointer P has the value zero
```

- The `-ftrapuv` (Linux OS and Mac OS X) or `/Qtrapuv` (Windows OS) option is useful in detecting uninitialized variables. It sets uninitialized local variables that are allocated on the stack to a value that is typically interpreted as a very large integer or an invalid address. References to these variables, which are not properly initialized by the application, are likely to cause run-time errors that can help you detect coding errors.
- The `-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS) option generates extra information in the object file to provide source file traceback information when a severe error occurs at run time. This simplifies the task of locating the cause of severe run-time errors. Without `traceback`, you could try to locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when a severe error occurs.Certain traceback-related information accompanies severe run-time errors, as described in Using Traceback Information.
- The `-fpe` (Linux OS and Mac OS X) or `/fpe` (Windows OS) option controls the handling of floating-point arithmetic exceptions (IEEE arithmetic) at run time. If you specify the `-fpe3` (Linux OS and Mac OS X) or `/fpe:3` (Windows OS) compiler option, all floating-point exceptions are disabled, allowing IEEE exceptional values and program continuation. In contrast, specifying `-fpe0` or `/fpe:0` stops execution when an exceptional value (such as a NaN) is generated or when attempting to use a denormalized number, which usually allows you to localize the cause of the error.
- The `-warn` and `-nowarn` (Linux OS and Mac OS X) or `/warn` and `/nowarn` (Windows OS) options control compile-time warning messages, which, in some circumstances, can help determine the cause of a run-time error.
- On Linux OS and Mac OS X, the `-fexceptions` option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines.
- On Windows OS, the Compilation Diagnostics Options in the IDE control compile-time diagnostic messages, which, in some circumstances can help determine the cause of a run-time error.

List of Run-Time Error Messages

This section lists the errors processed by the Intel Fortran run-time library (RTL). For each error, the table provides the error number, the severity code, error message text, condition symbol name, and a detailed description of the error.

To define the condition symbol values (PARAMETER statements) in your program, include the following file:

`for_iosdef.for`

As described in the table, the severity of the message determines which of the following occurs:

- with `info` and `warning`, program execution continues
- with `error`, the results may be incorrect
- with `severe`, program execution stops (unless a recovery method is specified)

In the last case, to prevent program termination, you must include either an appropriate I/O error-handling specifier and recompile or, for certain errors, change the default action of a signal before you run the program again.

In the following table, the first column lists error numbers returned to IOSTAT variables when an I/O error is detected.

The first line of the second column provides the message as it is displayed (following *`forrtl:`*), including the severity level, message number, and the message text. The following lines of the second column contain the status condition symbol (such as FOR$IOS_INCRECTYP) and an explanation of the message.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
1[1]	**severe (1): Not a Fortran-specific error** FOR$IOS_NOTFORSPE. An error in the user program or in the RTL was not an Intel Fortran-specific error and was not reportable through any other Intel Fortran run-time messages.
8	**severe (8): Internal consistency check failure** FOR$IOS_BUG_CHECK. Internal error. Please check that the program is correct. Recompile if an error existed in the program. If this error persists, submit a problem report.
9	**severe (9): Permission to access file denied** FOR$IOS_PERACCFIL. Check the permissions of the specified file and whether the network device is mapped and available. Make sure the correct file and device was being accessed. Change the protection, specific file, or process used before rerunning the program.
10	**severe (10): Cannot overwrite existing file**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_CANOVEEXI. Specified file xxx already exists when OPEN statement specified STATUS='NEW' (create new file) using I/O unit x. Make sure correct file name, directory path, unit, and so forth were specified in the source program. Decide whether to: • Rename or remove the existing file before rerunning the program. • Modify the source file to specify different file specification, I/O unit, or OPEN statement STATUS.
11[1]	**info (11): Unit not connected** FOR$IOS_UNINOTCON. The specified unit was not open at the time of the attempted I/O operation. Check if correct unit number was specified. If appropriate, use an OPEN statement to explicitly open the file (connect the file to the unit number).
17	**severe (17): Syntax error in NAMELIST input** FOR$IOS_SYNERRNAM. The syntax of input to a namelist-directed READ statement was incorrect.
18	**severe (18): Too many values for NAMELIST variable** FOR$IOS_TOOMANVAL. An attempt was made to assign too many values to a variable during a namelist READ statement.
19	**severe (19): Invalid reference to variable in NAMELIST input** FOR$IOS_INVREFVAR. One of the following conditions occurred: • The variable was not a member of the namelist group. • An attempt was made to subscript a scalar variable. • A subscript of the array variable was out-of-bounds. • An array variable was specified with too many or too few subscripts for the variable. • An attempt was made to specify a substring of a noncharacter variable or array name. • A substring specifier of the character variable was out-of-bounds. • A subscript or substring specifier of the variable was not an integer constant. • An attempt was made to specify a substring by using an unsubscripted array variable.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
20	**severe (20): REWIND error** FOR$IOS_REWERR. One of the following conditions occurred: • The file was not a sequential file. • The file was not opened for sequential or append access. • The Intel Fortran RTL I/O system detected an error condition during execution of a REWIND statement.
21	**severe (21): Duplicate file specifications** FOR$IOS_DUPFILSPE. Multiple attempts were made to specify file attributes without an intervening close operation. A DEFINE FILE statement was followed by another DEFINE FILE statement or an OPEN statement.
22	**severe (22): Input record too long** FOR$IOS_INPRECTOO. A record was read that exceeded the explicit or default record length specified when the file was opened. To read the file, use an OPEN statement with a RECL= value (record length) of the appropriate size.
23	**severe (23): BACKSPACE error** FOR$IOS_BACERR. The Intel Fortran RTL I/O system detected an error condition during execution of a BACKSPACE statement.
24[1]	**severe (24): End-of-file during read** FOR$IOS_ENDDURREA. One of the following conditions occurred: • An Intel Fortran RTL I/O system end-of-file condition was encountered during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification. • An end-of-file record written by the ENDFILE statement was encountered during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification. • An attempt was made to read past the end of an internal file character string or array during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification. This error is returned by END and ERRSNS.
25	**severe (25): Record number outside range**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_RECNUMOUT. A direct access READ, WRITE, or FIND statement specified a record number outside the range specified when the file was opened.
26	**severe (26): OPEN or DEFINE FILE required** FOR$IOS_OPEDEFREQ. A direct access READ, WRITE, or FIND statement was attempted for a file when no prior DEFINE FILE or OPEN statement with ACCESS='DIRECT' was performed for that file.
27	**severe (27): Too many records in I/O statement** FOR$IOS_TOOMANREC. An attempt was made to do one of the following: • Read or write more than one record with an ENCODE or DECODE statement. • Write more records than existed.
28	**severe (28): CLOSE error** FOR$IOS_CLOERR. An error condition was detected by the Intel Fortran RTL I/O system during execution of a CLOSE statement.
29	**severe (29): File not found** FOR$IOS_FILNOTFOU. A file with the specified name could not be found during an open operation.
30	**severe (30): Open failure** FOR$IOS_OPEFAI. An error was detected by the Intel Fortran RTL I/O system while attempting to open a file in an OPEN, INQUIRE, or other I/O statement. This message is issued when the error condition is not one of the more common conditions for which specific error messages are provided. It can occur when an OPEN operation was attempted for one of the following: • Segmented file that was not on a disk or a raw magnetic tape • Standard I/O file that had been closed
31	**severe (31): Mixed file access modes** FOR$IOS_MIXFILACC. An attempt was made to use any of the following combinations: • Formatted and unformatted operations on the same unit • An invalid combination of access modes on a unit, such as direct and sequential

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	• An Intel Fortran RTL I/O statement on a logical unit that was opened by a program coded in another language
32	**severe (32): Invalid logical unit number** FOR$IOS_INVLOGUNI. A logical unit number greater than 2,147,483,647 or less than zero was used in an I/O statement.
33	**severe (33): ENDFILE error** FOR$IOS_ENDFILERR. One of the following conditions occurred: • The file was not a sequential organization file with variable-length records. • The file was not opened for sequential, append, or direct access. • An unformatted file did not contain segmented records. • The Intel Fortran RTL I/O system detected an error during execution of an ENDFILE statement.
34	**severe (34): Unit already open** FOR$IOS_UNIALROPE. A DEFINE FILE statement specified a logical unit that was already opened.
35	**severe (35): Segmented record format error** FOR$IOS_SEGRECFOR. An invalid segmented record control data word was detected in an unformatted sequential file. The file was probably either created with RECORDTYPE='FIXED' or 'VARIABLE' in effect, or was created by a program written in a language other than Fortran or Fortran 90.
36	**severe (36): Attempt to access non-existent record** FOR$IOS_ATTACCNON. A direct-access `READ` or `FIND` statement attempted to access beyond the end of a relative file (or a sequential file on disk with fixed-length records) or access a record that was previously deleted from a relative file.
37	**severe (37): Inconsistent record length** FOR$IOS_INCRECLEN. An attempt was made to open a direct access file without specifying a record length.
38	**severe (38): Error during write**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_ERRDURWRI. The Intel Fortran RTL I/O system detected an error condition during execution of a WRITE statement.
39	**severe (39): Error during read** FOR$IOS_ERRDURREA. The Intel Fortran RTL I/O system detected an error condition during execution of a READ statement.
40	**severe (40): Recursive I/O operation** FOR$IOS_RECIO_OPE. While processing an I/O statement for a logical unit, another I/O operation on the same logical unit was attempted, such as a function subprogram that performs I/O to the same logical unit that was referenced in an expression in an I/O list or variable format expression.
41	**severe (41): Insufficient virtual memory** FOR$IOS_INSVIRMEM. The Intel Fortran RTL attempted to exceed its available virtual memory while dynamically allocating space. To overcome this problem, investigate increasing the data limit. Before you try to run this program again, wait until the new system resources take effect. Note: This error can be returned by STAT in an ALLOCATE or a DEALLOCATE statement.
42	**severe (42): No such device** FOR$IOS_NO_SUCDEV. A pathname included an invalid or unknown device name when an OPEN operation was attempted.
43	**severe (43): File name specification error** FOR$IOS_FILNAMSPE. A pathname or file name given to an OPEN or INQUIRE statement was not acceptable to the Intel Fortran RTL I/O system.
44	**severe (44): Inconsistent record type** FOR$IOS_INCRECTYP. The RECORDTYPE value in an OPEN statement did not match the record type attribute of the existing file that was opened.
45	**severe (45): Keyword value error in OPEN statement** FOR$IOS_KEYVALERR. An improper value was specified for an OPEN or CLOSE statement specifier requiring a value.
46	**severe (46): Inconsistent OPEN/CLOSE parameters**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_INCOPECLO. Specifications in an OPEN or CLOSE statement were inconsistent. Some invalid combinations follow: • READONLY or ACTION='READ' with STATUS='NEW' or STATUS='SCRATCH' • READONLY with STATUS='REPLACE', ACTION='WRITE', or ACTION='READWRITE' • ACCESS='APPEND' with READONLY, ACTION='READ', STATUS='NEW', or STATUS='SCRATCH' • DISPOSE='SAVE', 'PRINT', or 'SUBMIT' with STATUS='SCRATCH' • DISPOSE='DELETE' with READONLY • CLOSE statement STATUS='DELETE' with OPEN statement READONLY • ACCESS='DIRECT' with POSITION='APPEND' or 'ASIS'
47	**severe (47): Write to READONLY file** FOR$IOS_WRIREAFIL. A write operation was attempted to a file that was declared ACTION='READ' or READONLY in the OPEN statement that is currently in effect.
48	**severe (48): Invalid argument to Fortran Run-Time Library** FOR$IOS_INVARGFOR. The compiler passed an invalid or improperly coded argument to the Intel Fortran RTL. This can occur if the compiler is newer than the RTL in use.
51	**severe (51): Inconsistent file organization** FOR$IOS_INCFILORG. The file organization specified in an OPEN statement did not match the organization of the existing file.
53	**severe (53): No current record** FOR$IOS_NO_CURREC. Attempted to execute a REWRITE statement to rewrite a record when the current record was undefined. To define the current record, execute a successful READ statement. You can optionally perform an INQUIRE statement on the logical unit after the READ statement and before the REWRITE statement. No other operations on the logical unit may be performed between the READ and REWRITE statements.
55	**severe (55): DELETE error** FOR$IOS_DELERR. An error condition was detected by the Intel Fortran RTL I/O system during execution of a DELETE statement.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
57	**severe (57): FIND error** FOR$IOS_FINERR. The Intel Fortran RTL I/O system detected an error condition during execution of a FIND statement.
58[1]	**info (58): Format syntax error at or near xx** FOR$IOS_FMTSYN. Check the statement containing *xx*, a character substring from the format string, for a format syntax error. For more information, see the FORMAT statement.
59	**severe (59): List-directed I/O syntax error** FOR$IOS_LISIO_SYN. The data in a list-directed input record had an invalid format, or the type of the constant was incompatible with the corresponding variable. The value of the variable was unchanged. Note: The ERR transfer is taken after completion of the I/O statement for error number 59. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
60	**severe (60): Infinite format loop** FOR$IOS_INFFORLOO. The format associated with an I/O statement that included an I/O list had no field descriptors to use in transferring those values.
61	**severe or info(61): Format/variable-type mismatch** FOR$IOS_FORVARMIS. An attempt was made either to read or write a real variable with an integer field descriptor (I, L, O, Z, B), or to read or write an integer or logical variable with a real field descriptor (D, E, or F). To suppress this error message, see the description of /check:noformat. Note: The severity depends on the -check keywords or /check:keywords option used during the compilation command. The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
62	**severe (62): Syntax error in format** FOR$IOS_SYNERRFOR. A syntax error was encountered while the RTL was processing a format stored in an array or character variable.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
63	**error or info(63): Output conversion error** FOR$IOS_OUTCONERR. During a formatted output operation, the value of a particular number could not be output in the specified field length without loss of significant digits. When this situation is encountered, the overflowed field is filled with asterisks to indicate the error in the output record. If no ERR address has been defined for this error, the program continues after the error message is displayed. To suppress this error message, see the description of /check:nooutput_conversion. Note: The severity depends on the -check keywords or /check:keywords option used during the compilation command. The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
64	**severe (64): Input conversion error** FOR$IOS_INPCONERR. During a formatted input operation, an invalid character was detected in an input field, or the input value overflowed the range representable in the input variable. The value of the variable was set to zero. Note: The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
65	**error (65): Floating invalid** FOR$IOS_FLTINV. During an arithmetic operation, the floating-point values used in a calculation were invalid for the type of operation requested or invalid exceptional values. For example, the error can occur if you request a log of the floating-point values 0.0 or a negative number. For certain arithmetic expressions, specifying the /check:nopower option can suppress this message.
66	**severe (66): Output statement overflows record** FOR$IOS_OUTSTAOVE. An output statement attempted to transfer more data than would fit in the maximum record size.
67	**severe (67): Input statement requires too much data** FOR$IOS_INPSTAREQ. Attempted to read more data than exists in a record with an unformatted `READ` statement or with a formatted sequential `READ` statement from a file opened with a PAD specifier value of 'NO'.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
68	**severe (68): Variable format expression value error** FOR$IOS_VFEVALERR. The value of a variable format expression was not within the range acceptable for its intended use; for example, a field width was less than or equal to zero. A value of 1 was assumed, except for a P edit descriptor, for which a value of zero was assumed. Note: The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
69[1]	**error (69): Process interrupted (SIGINT)** FOR$IOS_SIGINT. The process received the signal SIGINT. Determine source of this interrupt signal (described in `signal(3)`).
70[1]	**severe (70): Integer overflow** FOR$IOS_INTOVF. During an arithmetic operation, an integer value exceeded byte, word, or longword range. The result of the operation was the correct low-order part. Consider specifying a larger integer data size (modify source program or, for an INTEGER declaration, possibly use the /integer-size:size option).
71[1]	**severe (71): Integer divide by zero** FOR$IOS_INTDIV. During an integer arithmetic operation, an attempt was made to divide by zero. The result of the operation was set to the dividend, which is equivalent to division by 1.
72[1]	**error (72): Floating overflow** FOR$IOS_FLTOVF. During an arithmetic operation, a floating-point value exceeded the largest representable value for that data type. See Data Representation for ranges of the various data types.
73[1]	**error (73): Floating divide by zero** FOR$IOS_FLTDIV. During a floating-point arithmetic operation, an attempt was made to divide by zero.
74[1]	**error (74): Floating underflow**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_FLTUND. During an arithmetic operation, a floating-point value became less than the smallest finite value for that data type. Depending on the values of the /fpe:*n* option, the underflowed result was either set to zero or allowed to gradually underflow. See the Data Representation for ranges of the various data types.
75[1]	**error (75): Floating point exception** FOR$IOS_SIGFPE. A floating-point exception occurred. Possible causes include: • Division by zero • Overflow • An invalid operation, such as subtraction of infinite values, multiplication of zero by infinity without signs), division of zero by zero or infinity by infinity • Conversion of floating-point to fixed-point format when an overflow prevents conversion
76[1]	**error (76): IOT trap signal** FOR$IOS_SIGIOT. Core dump file created. Examine core dump for possible cause of this IOT signal.
77[1]	**severe (77): Subscript out of range** FOR$IOS_SUBRNG. An array reference was detected outside the declared array bounds.
78[1]	**error (78): Process killed** FOR$IOS_SIGTERM. The process received a signal requesting termination of this process. Determine the source of this software termination signal.
79[1]	**error (79): Process quit** FOR$IOS_SIGQUIT. The process received a signal requesting termination of itself. Determine the source of this quit signal.
95[1]	**info (95): Floating-point conversion failed** FOR$IOS_FLOCONFAI. The attempted unformatted read or write of nonnative floating-point data failed because the floating-point value: • Exceeded the allowable maximum value for the equivalent native format and was set equal to infinity (plus or minus)

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	• Was infinity (plus or minus) and was set to infinity (plus or minus) • Was invalid and was set to not a number (NaN) Very small numbers are set to zero (0). This error could be caused by the specified nonnative floating-point format not matching the floating-point format found in the specified file. Check the following: • The correct file was specified. • The record layout matches the format Intel Fortran is expecting. • The ranges for the data being used (see Data Representation). • The correct nonnative floating-point data format was specified (see Supported Native and Nonnative Numeric Formats).
96	**info (96): F_UFMTENDIAN environment variable was ignored:erroneous syntax** FOR$IOS_UFMTENDIAN. Syntax for specifying whether little endian or big endian conversion is performed for a given Fortran unit was incorrect. Even though the program will run, the results might not be correct if you do not change the value of F_UFMTENDIAN. For correct syntax, see Environment Variable F_UFMTENDIAN Method.
108	**Severe (108): Cannot stat file** FOR$IOS_CANSTAFILE. Make sure correct file and unit were specified.
120	**severe (120): Operation requires seek ability** FOR$IOS_OPEREQSEE. Attempted an operation on a file that requires the ability to perform seek operations on that file. Make sure the correct unit, directory path, and file were specified.
134	**No associated message** Program was terminated internally through abort().
138[1]	**severe (138): Array index out of bounds** FOR$IOS_BRK_RANGE. An array subscript is outside the dimensioned boundaries of that array. Recompile with the /check:bounds option set.
139[1]	**severe: (139): Array index out of bounds for index nn**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_BRK_RANGE2. An array subscript is outside the dimensioned boundaries of that array. Recompile with the /check:bounds option set.
140[1]	**error (140): Floating inexact** FOR$IOS_FLTINE. A floating-point arithmetic or conversion operation gave a result that differs from the mathematically exact result. This trap is reported if the rounded result of an IEEE operation is not exact.
144[1]	**severe (144): Reserved operand** FOR$IOS_ROPRAND. The Intel Fortran RTL encountered a reserved operand while executing your program. Please report the problem to Intel.
145[1]	**severe (145): Assertion error** FOR$IOS_ASSERTERR. The Intel Fortran RTL encountered an assertion error. Please report the problem to Intel.
146[1]	**severe (146): Null pointer error** FOR$IOS_NULPTRERR. Attempted to use a pointer that does not contain an address. Modify the source program, recompile, and relink.
147[1]	**severe (147): Stack overflow** FOR$IOS_STKOVF. The Intel Fortran RTL encountered a stack overflow while executing your program.
148[1]	**severe (148): String length error** FOR$IOS_STRLENERR. During a string operation, an integer value appears in a context where the value of the integer is outside the permissible string length range. Recompile with the /check:bounds option.
149[1]	**severe (149): Substring error** FOR$IOS_SUBSTRERR. An array subscript is outside the dimensioned boundaries of an array. Recompile with the /check:bounds option.
150[1]	**severe (150): Range error** FOR$IOS_RANGEERR. An integer value appears in a context where the value of the integer is outside the permissible range.
151[1]	**severe (151): Allocatable array is already allocated**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_INVREALLOC. An allocatable array must not already be allocated when you attempt to allocate it. You must deallocate the array before it can again be allocated. Note: This error can be returned by STAT in an ALLOCATE statement.
152[1]	**severe (152): Unresolved contention for DEC Fortran RTL global resource** FOR$IOS_RESACQFAI. Failed to acquire an Intel Fortran RTL global resource for a reentrant routine. For a multithreaded program, the requested global resource is held by a different thread in your program. For a program using asynchronous handlers, the requested global resource is held by the calling part of the program (such as main program) and your asynchronous handler attempted to acquire the same global resource.
153[1]	**severe (153): Allocatable array or pointer is not allocated** FOR$IOS_INVDEALLOC. A Fortran 90 allocatable array or pointer must already be allocated when you attempt to deallocate it. You must allocate the array or pointer before it can again be deallocated. Note: This error can be returned by STAT in a DEALLOCATE statement.
154[1]	**severe(154): Array index out of bounds** FOR$IOS_RANGE. An array subscript is outside the dimensioned boundaries of that array. Recompile with the /check:bounds option set.
155[1]	**severe(155): Array index out of bounds for index nn** FOR$IOS_RANGE2. An array subscript is outside the dimensioned boundaries of that array. Recompile with the /check:bounds option set.
156[1]	**severe(156): GENTRAP code = hex dec** FOR$IOS_DEF_GENTRAP. The Intel Fortran RTL has detected an unknown GENTRAP code. The cause is most likely a software problem due to memory corruption, or software signalling an exception with an incorrect exception code. Try recompiling with the /check:bounds option set to see if that finds the problem.
157[1]	**severe(157): Program Exception - access violation** FOR$IOS_ACCVIO. The program tried to read from or write to a virtual address for which it does not have the appropriate access. Try recompiling with the /check:bounds option set, to see if the problem is an out-of-bounds memory reference or a argument mismatch that causes data to be treated as an address.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

Other causes of this error include:

- Mismatches in C vs. STDCALL calling mechanisms, causing the stack to become corrupted
- References to unallocated pointers
- Attempting to access a protected (for example, read-only) address

158[1] **severe(158): Program Exception - datatype misalignment**

FOR$IOS_DTYPE_MISALIGN. The Intel Fortran RTL has detected data that is not aligned on a natural boundary for the data type specified. For example, a REAL(8) data item aligned on natural boundaries has an address that is a multiple of 8. To ensure naturally aligned data, use the /align option.

This is an operating system error. See your operating system documentation for more information.

159[1] **severe(159): Program Exception - breakpoint**

FOR$IOS_PGM_BPT. The Intel Fortran RTL has encountered a breakpoint in the program.

This is an operating system error. See your operating system documentation for more information.

160[1] **severe(160): Program Exception - single step**

FOR$IOS_PGM_SS. A trace trap or other single-instruction mechanism has signaled that one instruction has been executed.

This is an operating system error. See your operating system documentation for more information.

161[1] **severe(161): Program Exception - array bounds exceeded**

FOR$IOS_PGM_BOUNDS. The program tried to access an array element that is outside the specified boundaries of the array. Recompile with the /check:bounds option set.

162[1] **severe(162): Program Exception - denormal floating-point operand**

FOR$IOS_PGM_DENORM. A floating-point arithmetic or conversion operation has a denormalized number as an operand. A denormalized number is smaller than the lowest value in the normal range for the data type specified. See Data Representation for ranges for floating-point types.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	Either locate and correct the source code causing the denormalized value or, if a denormalized value is acceptable, specify a different value for the /fpe compiler option to allow program continuation.
163[1]	**severe(163): Program Exception - floating stack check** FOR$IOS_PGM_FLTSTK. During a floating-point operation, the floating-point register stack on systems using IA-32 architecture overflowed or underflowed. This is a fatal exception. The most likely cause is calling a REAL function as if it were an INTEGER function or subroutine, or calling an INTEGER function or subroutine as if it were a REAL function. Carefully check that the calling code and routine being called agree as to how the routine is declared. If you are unable to resolve the issue, please send a problem report with an example to Intel.
164[1]	**severe(164): Program Exception - integer divide by zero** FOR$IOS_PGM_INTDIV. During an integer arithmetic operation, an attempt was made to divide by zero. Locate and correct the source code causing the integer divide by zero.
165[1]	**severe(165): Program Exception - integer overflow** FOR$IOS_PGM_INTOVF. During an arithmetic operation, an integer value exceeded the largest representable value for that data type. See Data Representation for ranges for INTEGER types.
166[1]	**severe(166): Program Exception - privileged instruction** FOR$IOS_PGM_PRIVINST. The program tried to execute an instruction whose operation is not allowed in the current machine mode. This is an operating system error. See your operating system documentation for more information.
167[1]	**severe(167): Program Exception - in page error** FOR$IOS_PGM_INPGERR. The program tried to access a page that was not present, so the system was unable to load the page. For example, this error might occur if a network connection was lost while trying to run a program over the network. This is an operating system error. See your operating system documentation for more information.
168[1]	**severe(168): Program Exception - illegal instruction**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_PGM_ILLINST. The program tried to execute an invalid instruction. This is an operating system error. See your operating system documentation for more information.
169[1]	**severe(169): Program Exception - noncontinuable exception** FOR$IOS_PGM_NOCONTEXCP. The program tried to continue execution after a noncontinuable exception occurred. This is an operating system error. See your operating system documentation for more information.
170[1]	**severe(170): Program Exception - stack overflow** FOR$IOS_PGM_STKOVF. The Intel Fortran RTL has detected a stack overflow while executing your program. See your Release Notes for information on how to increase stack size.
171[1]	**severe(171): Program Exception - invalid disposition** FOR$IOS_PGM_INVDISP. An exception handler returned an invalid disposition to the exception dispatcher. Programmers using a high-level language should never encounter this exception. This is an operating system error. See your operating system documentation for more information.
172[1]	**severe(172): Program Exception - exception code = hex dec** FOR$IOS_PGM_EXCP_CODE. The Intel Fortran RTL has detected an unknown exception code. This is an operating system error. See your operating system documentation for more information.
173[1]	**severe(173): A pointer passed to DEALLOCATE points to an array that cannot be deallocated** FOR$IOS_INVDEALLOC2. A pointer that was passed to DEALLOCATE pointed to an explicit array, an array slice, or some other type of memory that could not be deallocated in a `DEALLOCATE` statement. Only whole arrays previous allocated with an `ALLOCATE` statement may be validly passed to DEALLOCATE. Note: This error can be returned by STAT in a DEALLOCATE statement.
174[1]	**severe (174): SIGSEGV, message-text**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_SIGSEGV. One of two possible messages occurs for this error number: • `severe (174): SIGSEGV, segmentation fault occurred` This message indicates that the program attempted an invalid memory reference. Check the program for possible errors. • `severe (174): SIGSEGV, possible program stack overflow occurred` The following explanatory text also appears: `Program requirements exceed current stacksize resource limit.`
175[1]	**severe(175): DATE argument to DATE_AND_TIME is too short (LEN=n), required LEN=8** FOR$IOS_SHORTDATEARG. The number of characters associated with the DATE argument to the DATE_AND_TIME intrinsic was shorter than the required length. You must increase the number of characters passed in for this argument to be at least 8 characters in length. Verify that the TIME and ZONE arguments also meet their minimum lengths.
176[1]	**severe(176): TIME argument to DATE_AND_TIME is too short (LEN=n), required LEN=10** FOR$IOS_SHORTTIMEARG. The number of characters associated with the TIME argument to the DATE_AND_TIME intrinsic was shorter than the required length. You must increase the number of characters passed in for this argument to be at least 10 characters in length. Verify that the DATE and ZONE arguments also meet their minimum lengths.
177[1]	**severe(177): ZONE argument to DATE_AND_TIME is too short (LEN=n), required LEN=5** FOR$IOS_SHORTZONEARG. The number of characters associated with the ZONE argument to the DATE_AND_TIME intrinsic was shorter than the required length. You must increase the number of characters passed in for this argument to be at least 5 characters in length. Verify that the DATE and TIME arguments also meet their minimum lengths.
178[1]	**severe(178): Divide by zero** FOR$IOS_DIV. A floating-point or integer divide-by-zero exception occurred.
179[1]	**severe(179): Cannot allocate array - overflow on array size calculation**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_ARRSIZEOVF. An attempt to dynamically allocate storage for an array failed because the required storage size exceeds addressable memory. Note: This error can be returned by STAT in an ALLOCATE statement.
256	**severe (256): Unformatted I/O to unit open for formatted transfers** FOR$IOS_UNFIO_FMT. Attempted unformatted I/O to a unit where the OPEN statement (FORM specifier) indicated the file was formatted. Check that the correct unit (file) was specified. If the FORM specifier was not present in the OPEN statement and the file contains unformatted data, specify FORM='UNFORMATTED'in the OPEN statement. Otherwise, if appropriate, use formatted I/O (such as list-directed or namelist I/O).
257	**severe (257): Formatted I/O to unit open for unformatted transfers** FOR$IOS_FMTIO_UNF. Attempted formatted I/O (such as list-directed or namelist I/O) to a unit where the OPEN statement indicated the file was unformatted (FORM specifier). Check that the correct unit (file) was specified. If the FORM specifier was not present in the OPEN statement and the file contains formatted data, specify FORM='FORMATTED' in the OPEN statement. Otherwise, if appropriate, use unformatted I/O.
259	**severe (259): Sequential-access I/O to unit open for direct access** FOR$IOS_SEQIO_DIR. The OPEN statement for this unit number specified direct access and the I/O statement specifies sequential access. Check the OPEN statement and make sure the I/O statement uses the correct unit number and type of access.
264	**severe (264): operation requires file to be on disk or tape** FOR$IOS_OPEREQDIS. Attempted to use a BACKSPACE statement on such devices as a terminal.
265	**severe (265): operation requires sequential file organization and access** FOR$IOS_OPEREQSEQ. Attempted to use a BACKSPACE statement on a file whose organization was not sequential or whose access was not sequential. A BACKSPACE statement can only be used for sequential files opened for sequential access.
266[1]	**error (266): Fortran abort routine called** FOR$IOS_PROABOUSE. The program called the abort routine to terminate itself.
268[1]	**severe (268): End of record during read**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_ENDRECDUR. An end-of-record condition was encountered during execution of a nonadvancing I/O `READ` statement that did not specify the EOR branch specifier.
296[1]	**info(296): nn floating inexact traps** FOR$IOS_FLOINEEXC. The total number of floating-point inexact data traps encountered during program execution was *nn*. This summary message appears at program completion.
297[1]	**info (297): nn floating invalid traps** FOR$IOS_FLOINVEXC. The total number of floating-point invalid data traps encountered during program execution was *nn*. This summary message appears at program completion.
298[1]	**info (298): nn floating overflow traps** FOR$IOS_FLOOVFEXC. The total number of floating-point overflow traps encountered during program execution was *nn*. This summary message appears at program completion.
299[1]	**info (299): nn floating divide-by-zero traps** FOR$IOS_FLODIV0EXC. The total number of floating-point divide-by-zero traps encountered during program execution was *nn*. This summary message appears at program completion.
300[1]	**info (300): nn floating underflow traps** FOR$IOS_FLOUNDEXC. The total number of floating-point underflow traps encountered during program execution was *nn*. This summary message appears at program completion.
540	**severe (540): Array or substring subscript expression out of range** FOR$IOS_F6096. An expression used to index an array was smaller than the lower dimension bound or larger than the upper dimension bound.
541	**severe (541): CHARACTER substring expression out of range** FOR$IOS_F6097. An expression used to index a character substring was illegal.
542	**severe (542): Label not found in assigned GOTO list**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6098. The label assigned to the integer-variable name was not specified in the label list of the assigned GOTO statement.
543	**severe (543): INTEGER arithmetic overflow**
	FOR$IOS_F6099. This error occurs whenever integer arithmetic results in overflow.
544	**severe (544): INTEGER overflow on input**
	FOR$IOS_F6100. An integer item exceeded the legal size limits.
	An INTEGER (1) item must be in the range -127 to 128. An INTEGER (2) item must be in the range -32,767 to 32,768. An INTEGER (4) item must be in the range -2,147,483,647 to 2,147,483,648.
545	**severe (545): Invalid INTEGER**
	FOR$IOS_F6101. Either an illegal character appeared as part of an integer, or a numeric character larger than the radix was used in an alternate radix specifier.
546	**severe (546): REAL indefinite (uninitialized or previous error)**
	FOR$IOS_F6102. An invalid real number was read from a file, an internal variable, or the console. This can happen if an invalid number is generated by passing an illegal argument to an intrinsic function -- for example, SQRT(-1) or ASIN(2). If the invalid result is written and then later read, the error will be generated.
547	**severe (547): Invalid REAL**
	FOR$IOS_F103. An illegal character appeared as part of a real number.
548	**severe (548): REAL math overflow**
	FOR$IOS_F6104. A real value was too large. Floating-point overflows in either direct or emulated mode generate NaN (Not-A-Number) exceptions, which appear in the output field as asterisks (*) or the letters NAN.
550	**severe (550): INTEGER assignment overflow**
	FOR$IOS_F6106. This error occurs when assignment to an integer is out of range.
551	**severe (551): Formatted I/O not consistent with OPEN options**
	FOR$IOS_F6200. The program tried to perform formatted I/O on a unit opened with FORM='UNFORMATTED' or FORM='BINARY'.
552	**severe (552): List-directed I/O not consistent with OPEN options**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6201. The program tried to perform list-directed I/O on a file that was not opened with FORM='FORMATTED' and ACCESS='SEQUENTIAL'.
553	**severe (553): Terminal I/O not consistent with OPEN options** FOR$IOS_F6202. When a special device such as CON, LPT1, or PRN is opened in an OPEN statement, its access must be sequential and its format must be either formatted or binary. By default ACCESS='SEQUENTIAL' and FORM='FORMATTED' in OPEN statements. To generate this error the device's OPEN statement must contain an option not appropriate for a terminal device, such as ACCESS='DIRECT' or FORM='UNFORMATTED'.
554	**severe (554): Direct I/O not consistent with OPEN options** FOR$IOS_F6203. A REC= option was included in a statement that transferred data to a file that was opened with the ACCESS='SEQUENTIAL' option.
555	**severe (555): Unformatted I/O not consistent with OPEN options** FOR$IOS_F6204. If a file is opened with FORM='FORMATTED', unformatted or binary data transfer is prohibited.
556	**severe (556): A edit descriptor expected for CHARACTER** FOR$IOS_F6205. The A edit descriptor was not specified when a character data item was read or written using formatted I/O.
557	**severe (557): E, F, D, or G edit descriptor expected for REAL** FOR$IOS_F6206. The E, F, D, or G edit descriptor was not specified when a real data item was read or written using formatted I/O.
558	**severe (558): I edit descriptor expected for INTEGER** FOR$IOS_F6207. The I edit descriptor was not specified when an integer data item was read or written using formatted I/O.
559	**severe (559): L edit descriptor expected for LOGICAL** FOR$IOS_F6208. The L edit descriptor was not specified when a logical data item was read or written using formatted I/O.
560	**severe (560): File already open: parameter mismatch**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6209. An OPEN statement specified a connection between a unit and a filename that was already in effect. In this case, only the BLANK= option can have a different setting.
561	**severe (561): Namelist I/O not consistent with OPEN options** FOR$IOS_F6210. The program tried to perform namelist I/O on a file that was not opened with FORM='FORMATTED' and ACCESS='SEQUENTIAL.'
562	**severe (562): IOFOCUS option illegal with non-window unit** FOR$IOS_F6211. IOFOCUS was specified in an OPEN or INQUIRE statement for a non-window unit. The IOFOCUS option can only be used when the unit opened or inquired about is a QuickWin child window.
563	**severe (563): IOFOCUS option illegal without QuickWin** FOR$IOS_F6212. IOFOCUS was specified in an OPEN or INQUIRE statement for a non-QuickWin application. The IOFOCUS option can only be used when the unit opened or inquired about is a QuickWin child window.
564	**severe (564): TITLE illegal with non-window unit** FOR$IOS_F6213. TITLE was specified in an OPEN or INQUIRE statement for a non-window unit. The TITLE option can only be used when the unit opened or inquired about is a QuickWin child window.
565	**severe (565): TITLE illegal without QuickWin** FOR$IOS_F6214. TITLE was specified in an OPEN or INQUIRE statement for a non-QuickWin application. The TITLE option can only be used when the unit opened or inquired about is a QuickWin child window.
566	**severe (566): KEEP illegal for scratch file** FOR$IOS_F6300. STATUS='KEEP' was specified for a scratch file; this is illegal because scratch files are automatically deleted at program termination.
567	**severe (567): SCRATCH illegal for named file** FOR$IOS_F6301. STATUS='SCRATCH' should not be used in a statement that includes a filename.
568	**severe (568): Multiple radix specifiers**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6302. More than one alternate radix for numeric I/O was specified. F6302 can indicate an error in spacing or a mismatched format for data of different radices.
569	**severe (569): Illegal radix specifier** FOR$IOS_F6303. A radix specifier was not between 2 and 36, inclusive. Alternate radix constants must be of the form n#ddd... where n is a radix from 2 to 36 inclusive and ddd... are digits with values less than the radix. For example, 3#12 and 34#7AX are valid constants with valid radix specifiers. 245#7A and 39#12 do not have valid radix specifiers and generate error 569 if input.
570	**severe (570): Illegal STATUS value** FOR$IOS_F6304. An illegal value was used with the STATUS option. STATUS accepts the following values: • 'KEEP' or 'DELETE' when used with CLOSE statements • 'OLD', 'NEW', 'SCRATCH', or 'UNKNOWN' when used with OPEN statements
571	**severe (571): Illegal MODE value** FOR$IOS_F6305. An illegal value was used with the MODE option. MODE accepts the values 'READ', 'WRITE', or 'READWRITE'.
572	**severe (572): Illegal ACCESS value** FOR$IOS_F6306. An illegal value was used with the ACCESS option. ACCESS accepts the values 'SEQUENTIAL' and 'DIRECT'.
573	**severe (573): Illegal BLANK value** FOR$IOS_F6307. An illegal value was used with the BLANK option. BLANK accepts the values 'NULL' and 'ZERO'.
574	**severe (574): Illegal FORM value** FOR$IOS_F6308. An illegal value was used with the FORM option. FORM accepts the following values: 'FORMATTED', 'UNFORMATTED', and 'BINARY'.
575	**severe (575): Illegal SHARE value** FOR$IOS_F6309. An illegal value was used with the SHARE option.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	SHARE accepts the values 'COMPAT', 'DENYRW', 'DENYWR', 'DENYRD', and 'DENYNONE'.
577	**severe (577): Illegal record number** FOR$IOS_F6311. An invalid number was specified as the record number for a direct-access file. The first valid record number for direct-access files is 1.
578	**severe (578): No unit number associated with *** FOR$IOS_F6312. In an INQUIRE statement, the NUMBER option was specified for the file associated with * (console).
580	**severe (580): Illegal unit number** FOR$IOS_F6314. An illegal unit number was specified. Legal unit numbers can range from 0 through 2**31-1, inclusive.
581	**severe (581): Illegal RECL value** FOR$IOS_F6315. A negative or zero record length was specified for a direct file. The smallest valid record length for direct files is 1.
582	**severe (582): Array already allocated** FOR$IOS_F6316. The program attempted to `ALLOCATE` an already allocated array.
583	**severe (583): Array size zero or negative** FOR$IOS_F6317. The size specified for an array in an ALLOCATE statement must be greater than zero.
584	**severe (584): Non-HUGE array exceeds 64K** FOR$IOS_F6318.
585	**severe (585): Array not allocated** FOR$IOS_F6319. The program attempted to `DEALLOCATE` an array that was never allocated.
586	**severe (586): BACKSPACE illegal on terminal device** FOR$IOS_F6400. A BACKSPACE statement specified a unit connected to a terminal device such as a terminal or printer.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
587	**severe (587): EOF illegal on terminal device** FOR$IOS_F6401. An EOF intrinsic function specified a unit connected to a terminal device such as a terminal or printer.
588	**severe (588): ENDFILE illegal on terminal device** FOR$IOS_F6402. An ENDFILE statement specified a unit connected to a terminal device such as a terminal or printer.
589	**severe (589): REWIND illegal on terminal device** FOR$IOS_F6403. A `REWIND` statement specified a unit connected to a terminal device such as a terminal or printer.
590	**severe (590): DELETE illegal for read-only file** FOR$IOS_F6404. A CLOSE statement specified STATUS='DELETE' for a read-only file.
591	**severe (591): External I/O illegal beyond end of file** FOR$IOS_F6405. The program tried to access a file after executing an ENDFILE statement or after it encountered the end-of-file record during a read operation. A BACKSPACE, REWIND, or OPEN statement must be used to reposition the file before execution of any I/O statement that transfers data.
592	**severe (592): Truncation error: file closed** FOR$IOS_F6406.
593	**severe (593): Terminal buffer overflow** FOR$IOS_F6407. More than 131 characters were input to a record of a unit connected to the terminal (keyboard). Note that the operating system may impose additional limits on the number of characters that can be input to the terminal in a single record.
594	**severe (594): Comma delimiter disabled after left repositioning** FOR$IOS_F6408. If you have record lengths that exceed the buffer size associated with the record, (for instance, the record is a file with the buffer set by BLOCKSIZE in the OPEN statement), either you should not do left tabbing within the record, or you should not use commas as field delimiters. This is because commas are disabled as input field delimiters if left tabbing leaves the record positioned in a previous buffer.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

For example, consider you have a file LONG.DAT that is one continuous record with data fields separated by commas. You then set the buffer associated with the file to 512 bytes, read more than one buffer size of data, tab left to data in the previous buffer, and attempt to read further data, as follows:

```
    INTEGER value(300)
   OPEN (1, FILE = 'LONG.DAT', BLOCKSIZE = 512)s
   READ (1, 100) (value(i), i = 1, 300)s
100 FORMAT (290I2,TL50,10I2)
```

In this case, error 594 occurs.

599 **severe (599): File already connected to a different unit**

FOR$IOS_F6413. The program tried to connect an already connected file to a new unit.

A file can be connected to only one unit at a time.

600 **severe (600): Access not allowed**

FOR$IOS_F6414.

This error can be caused by one of the following:

- The filename specified in an OPEN statement was a directory.
- An OPEN statement tried to open a read-only file for writing.
- The file was opened with SHARE='DENYRW' by another process.

601 **severe (601): File already exists**

FOR$IOS_F6415. An OPEN statement specified STATUS='NEW' for a file that already exists.

602 **severe (602): File not found**

FOR$IOS_F6416. An OPEN statement specified STATUS='OLD' for a specified file or a directory path that does not exist.

603 **severe (603): Too many open files**

FOR$IOS_F6417. The program exceeded the number of open files the operating system allows.

604 **severe (604): Too many units connected**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6418. The program exceeded the number of units that can be connected at one time. Units are connected with the OPEN statement.
605	**severe (605): Illegal structure for unformatted file** FOR$IOS_F6419. The file was opened with FORM='UNFORMATTED' and ACCESS='SEQUENTIAL', but its internal physical structure was incorrect or inconsistent. Possible causes: the file was created in another mode or by a non-Fortran program.
606	**severe (606): Unknown unit number** FOR$IOS_F6420. A statement such as BACKSPACE or ENDFILE specified a file that had not yet been opened. (The READ and WRITE statements do not cause this problem because they prompt you for a file if the file has not been opened yet.)
607	**severe (607): File read-only or locked against writing** FOR$IOS_F6421. The program tried to transfer data to a file that was opened in read-only mode or locked against writing. The error message may indicate a CLOSE error when the fault is actually coming from WRITE. This is because the error is not discovered until the program tries to write buffered data when it closes the file.
608	**severe (608): No space left on device** FOR$IOS_F6422. The program tried to transfer data to a file residing on a device (such as a hard disk) that was out of storage space.
609	**severe (609): Too many threads** FOR$IOS_F6423. Too many threads were active simultaneously. At most, 32 threads can be active at one time. Close any unnecessary processes or child windows within your application.
610	**severe (610): Invalid argument** FOR$IOS_F6424.
611	**severe (611): BACKSPACE illegal for SEQUENTIAL write-only files** FOR$IOS_F6425. The BACKSPACE statement is not allowed in files opened with MODE='WRITE' (write-only status) because BACKSPACE requires reading the previous record in the file to provide positioning.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	Resolve the problem by giving the file read access or by avoiding the BACKSPACE statement. Note that the REWIND statement is valid for files opened as write-only.
612	**severe (612): File not open for reading or file locked** FOR$IOS_F6500. The program tried to read from a file that was not opened for reading or was locked.
613	**severe (613): End of file encountered** FOR$IOS_F6501. The program tried to read more data than the file contains.
614	**severe (614): Positive integer expected in repeat field** FOR$IOS_F6502. When the *i***c* form is used in list-directed input, the *i* must be a positive integer. For example, consider the following statement: `READ(*,*) a, b` Input 2*56.7 is accepted, but input 2.1*56.7 returns error 614.
615	**severe (615): Multiple repeat field** FOR$IOS_F6503. In list-directed input of the form *i***c*, an extra repeat field was used. For example, consider the following: `READ(*,*) I, J, K` Input of 2*1*3 returns this error. The 2*1 means send two values, each 1; the *3 is an error.
616	**severe (616): Invalid number in input** FOR$IOS_F6504. Some of the values in a list-directed input record were not numeric. For example, consider the following: `READ(*,*) I, J` The preceding statement would cause this error if the input were: 123 'abc'.
617	**severe (617): Invalid string in input** FOR$IOS_F6505. A string item was not enclosed in single quotation marks.
618	**severe (618): Comma missing in COMPLEX input** FOR$IOS_F6506. When using list-directed input, the real and imaginary components of a complex number were not separated by a comma.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
619	**severe (619): T or F expected in LOGICAL read** FOR$IOS_F6507. The wrong format was used for the input field for logical data. The input field for logical data consists of optional blanks, followed by an optional decimal point, followed by a T for true or F for false. The T or F may be followed by additional characters in the field, so that .TRUE. and .FALSE. are acceptable input forms.
620	**severe (620): Too many bytes read from unformatted record** FOR$IOS_F6508. The program tried to read more data from an unformatted file than the current record contained. If the program was reading from an unformatted direct file, it tried to read more than the fixed record length as specified by the RECL option. If the program was reading from an unformatted sequential file, it tried to read more data than was written to the record.
621	**severe (621): H or apostrophe edit descriptor illegal on input** FOR$IOS_F6509. Hollerith (H) or apostrophe edit descriptors were encountered in a format used by a READ statement.
622	**severe (622): Illegal character in hexadecimal input** FOR$IOS_F6510. The input field contained a character that was not hexadecimal. Legal hexadecimal characters are 0 - 9 and A - F.
623	**severe (623): Variable name not found** FOR$IOS_F6511. A name encountered on input from a namelist record is not declared in the corresponding NAMELIST statement.
624	**severe (624): Invalid NAMELIST input format** FOR$IOS_F6512. The input record is not in the correct form for namelist input.
625	**severe (625): Wrong number of array dimensions** FOR$IOS_F6513. In namelist input, an array name was qualified with a different number of subscripts than its declaration, or a non-array name was qualified.
626	**severe (626): Array subscript exceeds allocated area** FOR$IOS_F6514. A subscript was specified in namelist input which exceeded the declared dimensions of the array.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
627	**severe (627): Invalid subrange in NAMELIST input** FOR$IOS_F6515. A character item in namelist input was qualified with a subrange that did not meet the requirement that 1 <= e1 <= e2 <= len (where "len" is the length of the character item, "e1" is the leftmost position of the substring, and "e2" is the rightmost position of the substring).
628	**severe (628): Substring range specified on non-CHARACTER item** FOR$IOS_F6516. A non-CHARACTER item in namelist input was qualified with a substring range.
629	**severe (629): Internal file overflow** FOR$IOS_F6600. The program either overflowed an internal-file record or tried to write to a record beyond the end of an internal file.
630	**severe (630): Direct record overflow** FOR$IOS_F6601. The program tried to write more than the number of bytes specified in the RECL option to an individual record of a direct-access file.
631	**severe (631):Numeric field bigger than record size** FOR$IOS_F6602. The program tried to write a noncharacter item across a record boundary in list-directed or namelist output. Only character constants can cross record boundaries.
632	**severe (632): Heap space limit exceeded** FOR$IOS_F6700. The program ran out of heap space. The ALLOCATE statement and various internal functions allocate memory from the heap. This error will be generated when the last of the heap space is used up.
633	**severe (633): Scratch file name limit exceeded** FOR$IOS_F6701. The program exhausted the template used to generate unique scratch-file names. The maximum number of scratch files that can be open at one time is 26.
634	**severe (634): D field exceeds W field in ES edit descriptor** FOR$IOS_F6970. The specified decimal length D exceeds the specified total field width W in an ES edit descriptor.
635	**severe (635): D field exceeds W field in EN edit descriptor**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6971. The specified decimal length D exceeds the specified total field width W in an EN edit descriptor.
636	**severe (636): Exponent of 0 not allowed in format** FOR$IOS_F6972.

637	**severe (637): Integer expected in format**
	FOR$IOS_F6980. An edit descriptor lacked a required integer value. For example, consider the following:
	`WRITE(*, 100) I, J`
	`100 FORMAT (I2, TL, I2)`
	The preceding code will cause this error because an integer is expected after TL.

638	**severe (638): Initial left parenthesis expected in format** FOR$IOS_F6981. A format did not begin with a left parenthesis (( ).
639	**severe (639): Positive integer expected in format** FOR$IOS_F6982. A zero or negative integer value was used in a format. Negative integer values can appear only with the P edit descriptor. Integer values of 0 can appear only in the *d* and *m* fields of numeric edit descriptors.
640	**severe (640): Repeat count on nonrepeatable descriptor** FOR$IOS_F6983. One or more BN, BZ, S, SS, SP, T, TL, TR, /, $, :, or apostrophe (') edit descriptors had repeat counts associated with them.
641	**severe (641): Integer expected preceding H, X, or P edit descriptor** FOR$IOS_F6984. An integer did not precede a (nonrepeatable) H, X, or P edit descriptor. The correct formats for these descriptors are *n*H, *n*X, and *k*P, respectively, where *n* is a positive integer and *k* is an optionally signed integer.
642	**severe (642): N or Z expected after B in format** FOR$IOS_F6985. To control interpretation of embedded and trailing blanks within numeric input fields, you must specify BN (to ignore them) or BZ (to interpret them as zeros).
643	**severe (643): Format nesting limit exceeded**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6986. More than 16 sets of parentheses were nested inside the main level of parentheses in a format.
644	**severe (644): '.' expected in format**
	FOR$IOS_F6987. No period appeared between the *w* and *d* fields of a D, E, F, or G edit descriptor.
645	**severe (645): Unexpected end of format**
	FOR$IOS_F6988. An incomplete format was used.
	Improperly matched parentheses, an unfinished Hollerith (H) descriptor, or another incomplete descriptor specification can cause this error.
646	**severe (646): Unexpected character in format**

	FOR$IOS_F6989. A character that cannot be interpreted as part of a valid edit descriptor was used in a format. For example, consider the following:
	`WRITE(*, 100) I, J`
	`100 FORMAT (I2, TL4.5, I2)`

	The code will generate this error because TL4.5 is not a valid edit descriptor. An integer must follow TL.
647	**severe (647): M field exceeds W field in I edit descriptor**
	FOR$IOS_F6990. In syntax I*w*.*m*, the value of *m* cannot exceed the value of *w*.
648	**severe (648): Integer out of range in format**
	FOR$IOS_F6991. An integer value specified in an edit descriptor was too large to represent as a 4-byte integer.
649	**severe (649): format not set by ASSIGN**
	FOR$IOS_F6992. The format specifier in a READ, WRITE, or PRINT statement was an integer variable, but an ASSIGN statement did not properly assign it the statement label of a FORMAT statement in the same program unit.
650	**severe (650): Separator expected in format**
	FOR$IOS_F6993. Within format specifications, edit descriptors must be separated by commas or slashes (/).
651	**severe (651): %c or $: nonstandard edit descriptor in format**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6994.
652	**severe (652): Z: nonstandard edit descriptor in format** FOR$IOS_F6995. Z is not a standard edit descriptor in format. If you want to transfer hexadecimal values, you must use the edit descriptor form Z*w*[.*m*], where *w* is the field width and *m* is the minimum number of digits that must be in the field (including leading zeros).
653	**severe (653): DOS graphics not supported under Windows NT** FOR$IOS_F6996.
654	**severe (654): Graphics error** FOR$IOS_F6997. An OPEN statement in which IOFOCUS was TRUE, either explicitly or by default, failed because the new window could not receive focus. The window handle may be invalid, or closed, or there may be a memory resource problem.
655	**severe (655): Using QuickWin is illegal in console application** FOR$IOS_F6998. A call to QuickWin from a console application was encountered during execution.
656	**severe (656): Illegal 'ADVANCE' value** FOR$IOS_F6999. The ADVANCE option can only take the values 'YES' and 'NO'. ADVANCE='YES' is the default. ADVANCE is a READ statement option.
657	**severe (657): DIM argument to SIZE out of range** FOR$IOS_F6702. The argument specified for DIM must be greater than or equal to 1, and less than or equal to the number of dimensions in the specified array. Consider the following: `i = SIZE (array, DIM = dim)` In this case, `1 <= dim <=` *n*, where *n* is the number of dimensions in array.
658	**severe (657): Undefined POINTER used as argument to ASSOCIATED function** FOR$IOS_F6703. A POINTER used as an argument to the ASSOCIATED function must be defined; that is, assigned to a target, allocated, or nullified.
659	**severe (659): Reference to uninitialized POINTER**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6704. Except in an assignment statement, a pointer must not be referenced until it has been initialized: assigned to a target, allocated or nullified.
660	**severe (660): Reference to POINTER which is not associated** FOR$IOS_F6705. Except in an assignment statement and certain procedure references, a pointer must not be referenced until it has been associated: either assigned to a target or allocated.
661	**severe (661): Reference to uninitialized POINTER 'pointer'** FOR$IOS_F6706. Except in an assignment statement, a pointer must not be referenced until it has been initialized: assigned to a target, allocated or nullified.
662	**severe (662): reference to POINTER 'pointer' which is not associated** FOR$IOS_F6707. Except in an assignment statement and certain procedure references, a pointer must not be referenced until it has been associated: either assigned to a target or allocated.
663	**severe (663): Out of range: substring starting position 'pos' is less than 1** FOR$IOS_F6708. A substring starting position must be a positive integer variable or expression that indicates a position in the string: at least 1 and no greater than the length of the string.
664	**severe (664): Out of range: substring ending position 'pos' is greater than string length 'len'** FOR$IOS_F6709. A substring ending position must be a positive integer variable or expression that indicates a position in the string: at least 1 and no greater than the length of the string.
665	**severe (665): Subscript 'n' of 'str' (value 'val') is out of range ('first:last')** FOR$IOS_F6710. The subscript for a substring within a string is not a valid string position: at least 1 and no greater than the length of the string.
666	**severe (666): Subscript 'n' of 'str' (value 'val') is out of range ('first:*')** FOR$IOS_F6711. The subscript for a substring within a string is not a valid string position: at least 1 and no greater than the length of the string.
667	**severe (667): VECTOR argument to PACK has incompatible character length** FOR$IOS_F6712. The character length of elements in the VECTOR argument to PACK is not the same as the character length of elements in the array to be packed.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
668	**severe (668): VECTOR argument to PACK is too small** FOR$IOS_F6713. The VECTOR argument to PACK must have at least as many elements as there are true elements in MASK (the array that controls packing).
669	**severe (669): SOURCE and PAD arguments to RESHAPE have different character lengths** FOR$IOS_F6714. The character length of elements in the SOURCE and PAD arguments to PACK must be the same.
670	**severe (670): Element 'n' of SHAPE argument to RESHAPE is negative** FOR$IOS_F6715. The SHAPE vector specifies the shape of the reshaped array. Since an array cannot have a negative dimension, SHAPE cannot have a negative element.
671	**severe (671): SOURCE too small for specified SHAPE in RESHAPE, and no PAD** FOR$IOS_F6716. If there is no PAD array, the SOURCE argument to RESHAPE must have enough elements to make an array of the shape specified by SHAPE.
672	**severe (672): Out of memory** FOR$IOS_F6717. The system ran out of memory while trying to make the array specified by RESHAPE. If possible, reset your virtual memory size through the Windows Control Panel, or close unneccessary applications and deallocate all allocated arrays that are no longer needed.
673	**severe (673): SHAPE and ORDER arguments to RESHAPE have different sizes ('size1' and 'size2')** FOR$IOS_F6718. ORDER specifies the order of the array dimensions given in SHAPE, and they must be vectors of the same size.
674	**severe (674): Element 'n' of ORDER argument to RESHAPE is out of range ('range')** FOR$IOS_F6719. The ORDER argument specifies the order of the dimensions of the reshaped array, and it must be a permuted list of (1, 2, ..., *n*) where *n* is the highest dimension in the reshaped array.
675	**severe (675): Value 'val' occurs twice in ORDER argument to RESHAPE**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6720. The ORDER vector specifies the order of the dimensions of the reshaped array, and it must be a permuted list of (1, 2, ..., *n*) where *n* is the highest dimension in the reshaped array. No dimension can occur twice.
676	**severe (676): Impossible nextelt overflow in RESHAPE** FOR$IOS_F6721.
677	**severe (677): Invalid value 'dim' for argument DIM for SPREAD of rank 'rank' source** FOR$IOS_F6722. The argument specified for DIM to SPREAD must be greater than or equal to 1, and less than or equal to one larger than the number of dimensions (rank) of SOURCE. Consider the following statement: `result = SPREAD (SOURCE= array, DIM = dim, NCOPIES = k)` In this case, 1 <= dim <= *n*+ 1, where *n*is the number of dimensions in array.
678	**severe (678): Complex zero raised to power zero** FOR$IOS_F6723. Zero of any type (complex, real, or integer) cannot be raised to zero power.
679	**severe (679): Complex zero raised to negative power** FOR$IOS_F6724. Zero of any type (complex, real, or integer) cannot be raised to a negative power. Raising to a negative power inverts the operand.
680	**severe (680): Impossible error in NAMELIST input** FOR$IOS_F6725.
681	**severe (681):DIM argument to CSHIFT ('dim') is out of range** FOR$IOS_F6726. The optional argument DIM specifies the dimension along which to perform the circular shift, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array to be shifted. That is, 1 <=DIM <= *n*, where *n*is the number of dimensions in the array to be shifted.
682	**severe (682): DIM argument ('dim') to CSHIFT is out of range (1:'n')** FOR$IOS_F6727. The optional argument DIM specifies the dimension along which to perform the circular shift, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array to be shifted. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in the array to be shifted.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
683	**severe (683): Shape mismatch (dimension 'dim') between ARRAY and SHIFT in CSHIFT** FOR$IOS_F6728. The SHIFT argument to CSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the SHIFT must conform to the shape of the array being shifted in every dimension except the one being shifted along.
684	**severe (684): Internal error - bad arguments to CSHIFT_CA** FOR$IOS_F6729.
685	**severe (685): Internal error - bad arguments to CSHIFT_CAA** FOR$IOS_F6730.
686	**severe (686): DATE argument to DATE_AND_TIME is too short (LEN='len')** FOR$IOS_F6731. The character DATE argument must have a length of at least 8 to contain the complete value.
687	**severe (687): TIME argument to DATE_AND_TIME is too short (LEN='len')** FOR$IOS_F6732. The character TIME argument must have a length of at least 10 to contain the complete value.
688	**severe (688): ZONE argument to DATE_AND_TIME is too short (LEN='len')** FOR$IOS_F6733. The character ZONE argument must have a length of at least 5 to contain the complete value.
689	**severe (689): VALUES argument to DATE_AND_TIME is too small ('size' elements)** FOR$IOS_F6734. The integer VALUES argument must be a one-dimensional array with a size of at least 8 to hold all returned values.
690	**severe (690): Out of range: DIM argument to COUNT has value 'dim'** FOR$IOS_F6735. The optional argument DIM specifies the dimension along which to count true elements of MASK, and must be greater than or equal to 1 and less than or equal to the number of dimensions in MASK. That is, 1 <= DIM <= n, where n is the number of dimensions in MASK.
691	**severe (691): Out of range: DIM argument to COUNT has value 'dim' with MASK of rank 'rank'**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6736. The optional argument DIM specifies the dimension along which to count true elements of MASK, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in MASK. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in MASK.
692	**severe (692): Out of range: DIM argument to PRODUCT has value 'dim'**
	FOR$IOS_F6737. The optional argument DIM specifies the dimension along which to compute the product of elements in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array holding the elements to be multiplied.
693	**severe (693): Out of range: DIM argument to PRODUCT has value 'dim' with ARRAY of rank 'rank'**
	FOR$IOS_F6738. The optional argument DIM specifies the dimension along which to compute the product of elements in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) of the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array holding the elements to be multiplied.
694	**severe (694): Out of range: DIM argument to SUM has value 'dim' with ARRAY of rank 'rank'**
	FOR$IOS_F6739. The optional argument DIM specifies the dimension along which to sum the elements of an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) of the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array holding the elements to be summed.
695	**severe (695): Real zero raised to zero power**
	FOR$IOS_F6740. Zero of any type (real, complex, or integer) cannot be raised to zero power.
696	**severe (696): Real zero raised to negative power**
	FOR$IOS_F6741. Zero of any type (real, complex, or integer) cannot be raised to a negative power. Raising to a negative power inverts the operand.
697	**severe (697): Out of range: DIM argument to SUM has value 'dim'**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6742. The optional argument DIM specifies the dimension along which to sum the elements of an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array holding the elements to be summed.
698	**severe (698): DIM argument ('dim') to EOSHIFT is out of range (1:'n')**
	FOR$IOS_F6743. The optional argument DIM specifies the dimension along which to perform an end-off shift in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array holding the elements to be shifted.
699	**severe (699): Shape mismatch (dimension 'dim') between ARRAY and BOUNDARY in EOSHIFT**
	FOR$IOS_F6744. The BOUNDARY argument to EOSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the BOUNDARY must conform to the shape of the array being shifted in every dimension except the one being shifted along.
700	**severe (700): DIM argument to EOSHIFT is out of range ('dim')**
	FOR$IOS_F6745. The optional argument DIM specifies the dimension along which to perform an end-off shift in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array holding the elements to be shifted.
701	**severe (701): Shape mismatch (dimension 'dim') between ARRAY and SHIFT in EOSHIFT**
	FOR$IOS_F6746. The SHIFT argument to EOSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the SHIFT must conform to the shape of the array being shifted in every dimension except the one being shifted along.
702	**severe (702): BOUNDARY argument to EOSHIFT has wrong LEN ('len1 instead of len2')**
	FOR$IOS_F6747. The character length of elements in the BOUNDARY argument and in the array being end-off shifted must be the same.
703	**severe (703): BOUNDARY has LEN 'len' instead of 'len' to EOSHIFT**
	FOR$IOS_F6748.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
704	**severe (704): Internal error - bad arguments to EOSHIFT** FOR$IOS_F6749.
705	**severe (705): GETARG: value of argument 'num' is out of range** FOR$IOS_F6750. The value used for the number of the command-line argument to retrieve with GETARG must be 0 or a positive integer. If the number of the argument to be retrieved is greater than the actual number of arguments, blanks are returned, but no error occurs.
706	**severe (706): FLUSH: value of LUNIT 'num' is out of range** FOR$IOS_F6751. The unit number specifying which I/O unit to flush to its associated file must be an integer between 0 and 2**31-1, inclusive. If the unit number is valid, but the unit is not opened, error F6752 is generated.
707	**severe (707): FLUSH: Unit 'n' is not connected** FOR$IOS_F6752. The I/O unit specified to be flushed to its associated file is not connected to a file.
708	**severe (708): Invalid string length ('len') to ICHAR** FOR$IOS_F6753. The character argument to ICHAR must have length 1.
709	**severe (709): Invalid string length ('len') to IACHAR** FOR$IOS_F6754. The character argument to IACHAR must have length 1.
710	**severe (710): Integer zero raised to negative power** FOR$IOS_F6755. Zero of any type (integer, real, or complex) cannot be raised to a negative power. Raising to a negative power inverts the operand.
711	**severe (711): INTEGER zero raised to zero power** FOR$IOS_F6756. Zero of any type (integer, real, or complex) cannot be raised to zero power.
712	**severe (712): SIZE argument ('size') to ISHFTC intrinsic out of range** FOR$IOS_F6757. The argument SIZE must be positive and must not exceed the bit size of the integer being shifted. The bit size of this integer can be determined with the function BIT_SIZE.
713	**severe (713): SHIFT argument ('shift') to ISHFTC intrinsic out of range**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6758. The argument SHIFT to ISHFTC must be an integer whose absolute value is less than or equal to the number of bits being shifted: either all bits in the number being shifted or a subset specified by the optional argument SIZE.
714	**severe (714): Out of range: DIM argument to LBOUND has value 'dim'**
	FOR$IOS_F6759. The optional argument DIM specifies the dimension whose lower bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
715	**severe (715): Out of range: DIM argument ('dim') to LBOUND greater than ARRAY rank 'rank'**
	FOR$IOS_F6760. The optional argument DIM specifies the dimension whose lower bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.
716	**severe (716): Out of range: DIM argument to MAXVAL has value 'dim'**
	FOR$IOS_F6761. The optional argument DIM specifies the dimension along which maximum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
717	**severe (717): Out of range: DIM argument to MAXVAL has value 'dim' with ARRAY of rank 'rank'**
	FOR$IOS_F6762. The optional argument DIM specifies the dimension along which maximum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.
718	**severe (718): Cannot allocate temporary array -- out of memory**
	FOR$IOS_F6763. There is not enough memory space to hold a temporary array. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
719	**severe (719): Attempt to DEALLOCATE part of a larger object**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6764. An attempt was made to DEALLOCATE a pointer to an array subsection or an element within a derived type. The whole data object must be deallocated; parts cannot be deallocated.
720	**severe (720): Pointer in DEALLOCATE is ASSOCIATED with an ALLOCATABLE array** FOR$IOS_F6765. Deallocating a pointer associated with an allocatable target is illegal. Instead, deallocate the target the pointer points to, which frees memory and disassociates the pointer.
721	**severe (721): Attempt to DEALLOCATE an object which was not allocated** FOR$IOS_F6766. You cannot deallocate an array unless it has been previously allocated. You cannot deallocate a pointer whose target was not created by allocation. The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated.
722	**severe (722): Cannot ALLOCATE scalar POINTER -- out of memory** FOR$IOS_F6767. There is not enough memory space to allocate the pointer. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
723	**severe (723): DEALLOCATE: object not allocated/associated** FOR$IOS_F6768. You cannot deallocate an array unless it has been previously allocated. You cannot deallocate a pointer whose target was not created by allocation, or a pointer that has undefined association status. The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated.
724	**severe (724): Cannot ALLOCATE POINTER array -- out of memory** FOR$IOS_F6769. There is not enough memory space to allocate the POINTER array. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
725	**severe (725): DEALLOCATE: Array not allocated** FOR$IOS_F6770. It is illegal to DEALLOCATE an array that is not allocated. You can check the allocation status of an array before deallocating with the ALLOCATED function.
726	**severe (726): DEALLOCATE: Character array not allocated** FOR$IOS_F6771. It is illegal to DEALLOCATE an array that is not allocated. You can check the allocation status of an array before deallocating with the ALLOCATED function.
727	**severe (727): Cannot ALLOCATE allocatable array -- out of memory** FOR$IOS_F6772. There is not enough memory space to hold the array. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

728	**severe (728): Cannot allocate automatic object -- out of memory**
	FOR$IOS_F6773. There is not enough memory space to hold the automatic data object.
	Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
	An automatic data object is an object that is declared in a procedure subprogram or interface, is not a dummy argument, and depends on a nonconstant expression. For example:
	`SUBROUTINE  EXAMPLE (N)`
	`  DIMENSION A (N, 5), B(10*N)`
	The arrays A and B in the example are automatic data objects.

729	**severe (729): DEALLOCATE failure: ALLOCATABLE array is not ALLOCATED** FOR$IOS_F6774. It is illegal to DEALLOCATE an array that is not allocated. You can check the allocation status of an array before deallocating with the ALLOCATED function.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
730	**severe (730): Out of range: DIM argument to MINVAL has value 'dim'** FOR$IOS_F6775. The optional argument DIM specifies the dimension along which minimum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
731	**severe (731): Out of range: DIM argument to MINVAL has value 'dim' with ARRAY of rank 'rank'** FOR$IOS_F6776. The optional argument DIM specifies the dimension along which minimum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
732	**severe (732): P argument to MOD is double precision zero** FOR$IOS_F6777. MOD(A,P) is computed as A - INT(A/P) * P. So, P cannot be zero.
733	**severe (733): P argument to MOD is integer zero** FOR$IOS_F6778. MOD(A,P) is computed as A - INT(A/P) * P. So, P cannot be zero.
734	**severe (734): P argument to MOD is real zero** FOR$IOS_F6779. MOD(A,P) is computed as A - INT(A/P) * P. So, P cannot be zero.
735	**severe (735): P argument to MODULO is real zero** FOR$IOS_F6780. >MODULO(A,P) for real numbers is computed as A - FLOOR(A/P) * P. So, P cannot be zero.
736	**severe (736): P argument to MODULO is zero** FOR$IOS_F6781. In the function, MODULO(A,P), P cannot be zero.
737	**severe (737): Argument S to NEAREST is zero** FOR$IOS_F6782. The sign of the S argument to NEAREST(X,S) determines the direction of the search for the nearest number to X, and cannot be zero.
738	**severe (738): Heap storage exhausted** FOR$IOS_F6783.
739	**severe (739): PUT argument to RANDOM_SEED is too small**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

FOR$IOS_F6784. The integer array PUT must be greater than or equal to the number of integers the processor uses to set the seed value. This number can be determined by calling RANDOM_SEED with the SIZE argument. For example:

```
INTEGER, ALLOCATABLE SEED
CALL RANDOM_SEED( )           ! initialize processor
CALL RANDOM_SEED(SIZE = K)    ! get size of seed
ALLOCATE SEED(K)              ! allocate array
CALL RANDOM_SEED(PUT = SEED)  ! set the seed
```

Note that RANDOM_SEED can be called with at most one argument at a time.

740 **severe (740): GET argument to RANDOM_SEED is too small**

FOR$IOS_F6785. The integer array GET must be greater than or equal to the number of integers the processor uses to set the seed value. This number can be determined by calling RANDOM_SEED with the SIZE argument. For example:

```
INTEGER, ALLOCATABLE SEED
CALL RANDOM_SEED( )           ! initialize processor
CALL RANDOM_SEED(SIZE = K)    ! get size of seed
ALLOCATE SEED(K)              ! allocate array
CALL RANDOM_SEED(GET = SEED)  ! get the seed
```

Note that RANDOM_SEED can be called with at most one argument at a time.

741 **severe (741): Recursive I/O reference**

FOR$IOS_F6786.

742 **severe (742): Argument to SHAPE intrinsic is not PRESENT**

FOR$IOS_F6787.

743 **severe (743): Out of range: DIM argument to UBOUND had value 'dim'**

FOR$IOS_F6788. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.

744 **severe (744): DIM argument ('dim') to UBOUND greater than ARRAY rank 'rank'**

FOR$IOS_F6789. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
745	**severe (745): Out of range: UBOUND of assumed-size array with DIM==rank ('rank')** FOR$IOS_F6790. The optional argument DIM specifies the dimension whose upper bound is to be returned. An assumed-size array is a dummy argument in a subroutine or function, and the upper bound of its last dimension is determined by the size of actual array passed to it. Assumed-size arrays have no determined shape, and you cannot use UBOUND to determine the extent of the last dimension. You can use UBOUND to determine the upper bound of one of the fixed dimensions, in which case you must pass the dimension number along with the array name.
746	**severe (746): Out of range: DIM argument ('dim') to UBOUND greater than ARRAY rank** FOR$IOS_F6791. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.
747	**severe (747): Shape mismatch: Dimension 'shape' extents are 'ext1' and 'ext2'** FOR$IOS_F6792.
748	**severe (748): Illegal POSITION value** FOR$IOS_F6793. An illegal value was used with the POSITION specifier. POSITION accepts the following values: • 'ASIS' (the default) • 'REWIND' - on Fortran I/O systems, this is the same as 'ASIS' • 'APPEND'
749	**severe (749): Illegal ACTION value** FOR$IOS_F6794. An illegal value was used with the ACTION specifier. ACTION accepts the following values: • 'READ' • 'WRITE'

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	• 'READWRITE' - the default
750	**severe (750): DELIM= specifier not allowed for an UNFORMATTED file** FOR$IOS_F6795. The DELIM specifier is only allowed for files connected for formatted data transfer. It is used to delimit character constants in list-directed an namelist output.
751	**severe (751): Illegal DELIM value** FOR$IOS_F6796. An illegal value was used with the DELIM specifier. DELIM accepts the following values: • 'APOSTROPHE' • 'QUOTE' • 'NONE' - the default
752	**severe (752): PAD= specifier not allowed for an UNFORMATTED file** FOR$IOS_F6797. The PAD specifier is only allowed for formatted input records. It indicates whether the formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.
753	**severe (753): Illegal PAD= value** FOR$IOS_F6798. An illegal value was used with the PAD specifier. PAD accepts the following values: • 'NO' • 'YES' - the default
754	**severe (754): Illegal CARRIAGECONTROL=value** FOR$IOS_F6799. An illegal value was used with the CARRIAGECONTROL specifier. CARRIAGECONTROL accepts the following values: • 'FORTRAN' - default if the unit is connected to a terminal or console • 'LIST' - default for formatted files • 'NONE' - default for unformatted files

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
755	**severe (755): SIZE= specifier only allowed with ADVANCE='NO'** FOR$IOS_F6800. The SIZE specifier can only appear in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (indicating nonadvancing input).
756	**severe (756): Illegal character in binary input** FOR$IOS_F6801.
757	**severe (757): Illegal character in octal input** FOR$IOS_F6802.
758	**severe (758): End of record encountered** FOR$IOS_F6803.
759	**severe (759): Illegal subscript in namelist input record** FOR$IOS_F6804.

[1] Identifies errors not returned by IOSTAT.

Signal Handling (Linux* OS and Mac OS* X only)

A `signal` is an ab normal event generated by one of various sources, such as:

- A user of a terminal
- Program or hardware error
- Request of another program
- When a process is stopped to allow access to the control terminal

You can optionally set certain events to issue signals, for example:

- When a process resumes after being stopped
- When the status of a child process changes
- When input is ready at the terminal

Some signals terminate the receiving process if no action is taken (optionally creating a `core` file), while others are simply ignored unless the process has requested otherwise.

Except for certain signals, calling the `signal` or `sigaction` routine allows specified signals to be ignored or causes an interrupt (transfer of control) to the location of a user-written signal handler.

You can establish one of the following actions for a signal with a call to `signal`:

- Ignore the specified signal (identified by number).
- Use the default action for the specified signal, which can reset a previously established action.
- Transfer control from the specified signal to a procedure to receive the signal, specified by name.

Calling the `signal` routine lets you change the action for a signal, such as intercepting an operating system signal and preventing the process from being stopped.

The table below shows the signals that the Intel Fortran RTL arranges to catch when a program is started:

Signal	Intel Fortran RTL message
SIGFPE	`Floating-point exception` (number 75)
SIGINT	`Process interrupted` (number 69)
SIGIOT	`IOT trap signal` (number 76)
SIGQUIT	`Process quit` (number 79)
SIGSEGV	`Segmentation fault` (number 174)
SIGTERM	`Process killed` (number 78)

Calling the `signal` routine (specifying the numbers for these signals) results in overwriting the signal-handling facility set up by the Intel Fortran RTL. The only way to restore the default action is to save the returned value from the first call to `signal`.

When using a debugger, it may be necessary to enter a command to allow the Intel Fortran RTL to receive and handle the appropriate signals.

Overriding the Default Run-Time Library Exception Handler

To override the default run-time library exception handler on Linux OS and Mac OS X, your application must call `signal` to change the action for the signal of interest.

For example, assume that you want to change the signal action to cause your application to call abort() and generate a `core` file.

The following example adds a function named clear_signal_ to call signal() and change the action for the SIGABRT signal:

```
#include <signal.h>
void clear_signal_()
{
signal (SIGABRT, SIG_DFL);
}
int myabort_()
{
abort();
return 0;
}
```

A call to the `clear_signal()` local routine must be added to main. Make sure that the call appears before any call to the local `myabort()` routine:

```
program aborts
integer i

call clear_signal()

i = 3
if (i < 5) then
call myabort()
end if
end
```

Using Traceback Information

Using Traceback Information Overview

When a Fortran program terminates due to a severe error condition, the Fortran run-time system displays additional diagnostic information after the run-time message.

The Fortran run-time system attempts to walk back up the call chain and produce a report of the calling sequence leading to the error as part of the default diagnostic message report. This is known as traceback. The minimum information displayed includes:

- The standard Fortran run-time error message text that explains the error condition.
- A tabular report that contains one line per call stack frame. This information includes at least the image name and a hexadecimal PC in that image.

The information displayed under the Routine, Line, and Source columns depends on whether your program was compiled with the `-traceback` (Linux* OS and Mac OS* X) or `/traceback` (Windows* OS) option.

For example, if `-traceback` or `/traceback` is specified, the displayed information might resemble the following:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image              PC        Routine         Line     Source
libifcorert.dll    1000A3B2  Unknown         Unknown  Unknown
libifcorert.dll    1000A184  Unknown         Unknown  Unknown
libifcorert.dll    10009324  Unknown         Unknown  Unknown
libifcorert.dll    10009596  Unknown         Unknown  Unknown
libifcorert.dll    10024193  Unknown         Unknown  Unknown
teof.exe           004011A9  AGAIN                21  teof.for
teof.exe           004010DD  GO                   15  teof.for
teof.exe           004010A7  WE                   11  teof.for
teof.exe           00401071  HERE                  7  teof.for
teof.exe           00401035  TEOF                  3  teof.for
teof.exe           004013D9  Unknown         Unknown  Unknown
teof.exe           004012DF  Unknown         Unknown  Unknown
KERNEL32.dll       77F1B304  Unknown         Unknown  Unknown
```

If the same program is *not* compiled with the `-traceback` or `/traceback` option:

- The Routine name, Line number, and Source file columns would be reported as "Unknown."
- A link map file is usually needed to locate the cause of the error.

The `-traceback` or `/traceback` option provides program counter (PC) to source file line correlation information to appear in the displayed error message information, which simplifies the task of locating the cause of severe run-time errors.

For Fortran objects generated with `-traceback` or `/traceback`, the compiler generates additional information used by the Fortran run-time system to automatically correlate PC values to the routine name in which they occur, Fortran source file, and line number in the source file. This information is displayed in the run-time error diagnostic report.

Automatic PC correlation is only supported for Fortran code. For non-Fortran code, only the hexadecimal PC locations are reported.

Tradeoffs and Restrictions in Using Traceback

This topic describes tradeoffs and restrictions that apply to using traceback.

Effect on Image Size

Using the `-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS) option to get automatic PC correlation increases the size of an image. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PCs with a map file is acceptable.

The approach of providing automatic correlation information in the image was used so that no run-time penalty is incurred by building the information "on the fly" as your application executes. No run-time diagnostic code is invoked unless your application is terminating due to a severe error.

C Compiler Omit Frame Pointer Option on Systems Using IA-32 Architecture

The following routines are used to walk the stack:

- For Windows OS, the Windows API routine StackWalk( ) in imagehlp.dll
- For Linux OS and Mac OS X, _Unwind_ForcedUnwind( ), _Unwind_GetIP( ), _Unwind_GetRegionStart( ) and _Unwind_GetGr( ) routines in libunwind.so

In an environment using IA-32 architecture, there are no firm software calling standards documented. Compiler developers are under no constraints to use machine registers in any particular way or to hook up procedures in any particular way. The stack walking routines listed above use a set of heuristics to determine how to walk the call stack. That is, they make a "best guess" to determine how a program reached a particular point in the call chain. With C code that has been compiled with Visual C++* using the Omit Frame Pointer option -- either `-fomit-frame-pointer` (Linux OS and Mac OS X) or `/Oy` (Windows OS) -- this "best guess" is not usually the correct one.

If you are mixing Fortran and C code and you are concerned about stack tracing, consider disabling the `-fomit-frame-pointer` or `/Oy` option in your C compilations. Otherwise, traceback will most likely not work for you.

Stack Trace Failure

Programs can fail for a number of reasons, often with unpredictable consequences. Memory corruption by erroneously executing code is one possibility. Stack memory can be corrupted in such a way that the attempt to trace the call stack will result in access violations or other undesirable consequences. The stack-tracing run-time code is guarded with a local exception filter. If the traceback attempt fails due to a hard detectable condition, the run-time will report this in its diagnostic output message as:

```
Stack trace terminated abnormally
```

Be forewarned, however: It is also possible for memory to be corrupted in such a way that a stack trace can seem to complete successfully with no hint of a problem. The bit patterns it finds in corrupted memory where the stack used to be, and then uses to access memory, may constitute perfectly valid memory addresses for the program to be accessing. They just do not

happen to have any connection to what the stack used to look like. So, if it appears that the stack walk completed normally, but the reported PCs make no sense to you, then consider ignoring the stack trace output in diagnosing your problem.

Another condition that will disable the stack trace process is your program exiting because it has exhausted virtual memory resources.

The stack trace can fail if the run-time system cannot dynamically load libunwind.so (Linux OS and Mac OS X) or imagehlp.dll (Windows OS) or cannot find the necessary routines from that library. In this case, you still get the basic run-time diagnostic message; you will not get any call stack information.

Linker /incremental:no Option on Windows Operating Systems

The following applies to Windows operating systems only.

When incremental linking is enabled, automatic PC correlation does not work. Use of incremental linking always disables automatic PC correlation even if you specify `/traceback` during compilation.

When you use incremental linking, the default hexadecimal (hex) PC values will still appear in the output. To correlate from the hexadecimal PC values to routine containing the PC addresses requires use of a linker map file. However, if you request a map file during linking, incremental linking becomes disabled. Thus to allow any PC values generated for a run-time problem to be helpful, incremental linking must be disabled.

In the integrated development environment, you can use the Call stack display, so incremental linking is not a problem.

Sample Programs and Traceback Information

The following sections provide sample programs that show the use of traceback to locate the cause of the error:

- Example: End-of-File Condition, Program teof
- Example: Machine Exception Condition, Program ovf
- Example: Using Traceback in Mixed Fortran/C Applications, Program FPING and CPONG

Note that the hex PC's and contents of registers displayed in these program outputs are meant as representative examples of typical output. The PC's will change over time, as the libraries and other tools used to create an image change.

Example: End-of-File Condition, Program teof

In the following example, a READ statement creates an End-Of-File error, which the application has not handled:

```
  program teof
  integer*4 i,res
  i=here( )
  end
 integer*4 function here( )
  here = we( )
  end
 integer*4 function we( )
  we = go( )
  end
 integer*4 function go( )
  go = again( )
  end
 integer*4 function again( )
  integer*4 a
  open(10,file='xxx.dat',form='unformatted',status='unknown')
  read(10) a
  again=a
  end
```

The diagnostic output that results when this program is built with traceback enabled and linked against the single-threaded, shared Fortran run-time library on the IA-32 architecture platform is similar to the following:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image            PC        Routine         Line     Source
libifcorert.dll  1000A3B2  Unknown         Unknown  Unknown
libifcorert.dll  1000A184  Unknown         Unknown  Unknown
libifcorert.dll  10009324  Unknown         Unknown  Unknown
libifcorert.dll  10009596  Unknown         Unknown  Unknown
libifcorert.dll  10024193  Unknown         Unknown  Unknown
teof.exe         004011A9  AGAIN                21  teof.for
teof.exe         004010DD  GO                   15  teof.for
teof.exe         004010A7  WE                   11  teof.for
teof.exe         00401071  HERE                  7  teof.for
teof.exe         00401035  TEOF                  3  teof.for
teof.exe         004013D9  Unknown         Unknown  Unknown
teof.exe         004012DF  Unknown         Unknown  Unknown
KERNEL32.dll     77F1B304  Unknown         Unknown  Unknown
```

The first line of the output is the standard Fortran run-time error message. What follows is the result of walking the call stack in reverse order to determine where the error originated. Each line of output represents a call frame on the stack. Since the application was compiled with

`-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS), the PCs that fall in Fortran code are correlated to their matching routine name, line number and source module. PCs that are not in Fortran code are not correlated and are reported as "Unknown."

The first five frames show the calls to routines in the Fortran run-time library (in reverse order). Since the application was linked against the single threaded, shared version of the library, the image name reported is either libifcore.so (Linux OS and Mac OS X) or libifcorert.dll (Windows OS). These are the run-time routines that were called to do the `READ` and upon detection of the EOF condition, were invoked to report the error. In the case of an unhandled I/O programming error, there will always be a few frames on the call stack down in run-time code like this.

The stack frame of real interest to the Fortran developer is the first frame in image teof.exe which shows that the error originated in the routine named AGAIN in source module `teof.for` at line 21. Looking in the source code at line 21, you can see the Fortran `READ` statement that incurred the end-of-file condition.

The next four frames show the trail of calls in the Fortran user code that led to the routine that got the error (TEOF->HERE->WE->GO->AGAIN).

Finally, the bottom three frames are routines which handled the startup and initialization of the program.

If this program had been linked against the single-threaded, static Fortran run-time library, the output would then look like:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image          PC        Routine        Line     Source
teof.exe       004067D2  Unknown        Unknown  Unknown
teof.exe       0040659F  Unknown        Unknown  Unknown
teof.exe       00405754  Unknown        Unknown  Unknown
teof.exe       004059C5  Unknown        Unknown  Unknown
teof.exe       00403543  Unknown        Unknown  Unknown
teof.exe       004011A9  AGAIN               21  teof.for
teof.exe       004010DD  GO                  15  teof.for
teof.exe       004010A7  WE                  11  teof.for
teof.exe       00401071  HERE                 7  teof.for
teof.exe       00401035  TEOF                 3  teof.for
teof.exe       004202F9  Unknown        Unknown  Unknown
teof.exe       00416063  Unknown        Unknown  Unknown
KERNEL32.dll   77F1B304  Unknown        Unknown  Unknown
```

Notice that the initial five stack frames now show routines in image `teof.exe`, not libifcore.so (Linux OS and Mac OS X) or `libifcorert.dll` (Windows OS). The routines are the same five run-time routines as previously reported for the shared library case but since the application was linked against the archive library libifcore.a (Linux OS and Mac OS X) or the static Fortran

run-time library `libifcore.lib` (Windows OS), the object modules containing these routines were linked into the application image (`teof.exe`). You can use a map file to determine the locations of uncorrelated PCs.

Now suppose the application was compiled *`without`* traceback enabled and, once again, linked against the single-threaded, static Fortran library. The diagnostic output would appear as follows:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image              PC        Routine       Line     Source
teof.exe           00406792  Unknown       Unknown  Unknown
teof.exe           0040655F  Unknown       Unknown  Unknown
teof.exe           00405714  Unknown       Unknown  Unknown
teof.exe           00405985  Unknown       Unknown  Unknown
teof.exe           00403503  Unknown       Unknown  Unknown
teof.exe           00401169  Unknown       Unknown  Unknown
teof.exe           004010A8  Unknown       Unknown  Unknown
teof.exe           00401078  Unknown       Unknown  Unknown
teof.exe           00401048  Unknown       Unknown  Unknown
teof.exe           0040102F  Unknown       Unknown  Unknown
teof.exe           004202B9  Unknown       Unknown  Unknown
teof.exe           00416023  Unknown       Unknown  Unknown
KERNEL32.dll       77F1B304  Unknown       Unknown  Unknown
```

Without the correlation information in the image that `-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS) previously supplied, the Fortran run-time system cannot correlate PC's to routine name, line number, and source file. You can still use the map file to at least determine the routine names and what modules they are in.

Remember that compiling with `-traceback` or `/traceback` increases the size of your application's image because of the extra PC correlation information included in the image. You can see if the extra traceback information is included in an image (checking for the presence of a `.trace` section) by entering:

```
objdump -h your_app.exe (Linux OS)
otool -l your_app.exe (Mac OS X)
link -dump -summary your_app.exe (Windows OS)
```

Build your application with and without traceback and compare the file size of each image. Check the file size with a simple directory command.

For this simple `teof.exe` example, the traceback correlation information adds about 512 bytes to the image size. In a real application, this would probably be much larger. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PC's with a map file is acceptable.

If an error occurs when traceback was requested during compilation, the run-time library will produce the correlated call stack display.

If an error occurs when traceback was disabled during compilation, the run-time library will produce the uncorrelated call stack display.

If you do not want to see the call stack information displayed, you can set the environment variable `FOR_DISABLE_STACK_TRACE` to true. You will still get the Fortran run-time error message:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

Example: Machine Exception Condition, Program ovf

The following program generates a floating-point overflow exception when compiled with `-fpe 0` (Linux OS and Mac OS X) or `/fpe:0` (Windows OS):

```
  program ovf
  real*4 a
  a=1e37
  do i=1,10
    a=hey(a)
  end do
  print *, 'a= ', a
  end
 real*4 function hey(b)
  real*4 b
  hey = watch(b)
  end
 real*4 function watch(b)
  real*4 b
  watch = out(b)
  end
 real*4 function out(b)
  real*4 b
  out = below(b)
  end
 real*4 function below(b)
  real*4 b
  below = b*10.0e0
  end
```

Assume this program is compiled with the following:

- `-fpe 0` (Linux OS and Mac OS X) or `/fpe:0` (Windows OS)
- `-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS)
- `-O0` (Linux OS and Mac OS X) or `/Od` (Windows OS)

On a system based on IA-32 architecture, the traceback output is similar to the following:

```
forrtl: error (72): floating overflow
Image              PC        Routine          Line     Source
ovf.exe            00401161  BELOW               29  ovf.f90
ovf.exe            0040113C  OUT                 24  ovf.f90
ovf.exe            0040111B  WATCH               19  ovf.f90
ovf.exe            004010FA  HEY                 14  ovf.f90
ovf.exe            0040105B  OVF                  7  ovf.f90
ovf.exe            00432429  Unknown         Unknown  Unknown
ovf.exe            00426C74  Unknown         Unknown  Unknown
KERNEL32.dll       77F1B9EA  Unknown         Unknown  Unknown
```

Notice that unlike the previous example of an unhandled I/O programming error, the stack walk can begin right at the point of the exception. There are no run-time routines on the call stack to dig through. The overflow occurs in routine BELOW at PC 00401161, which is correlated to line 29 of the source file `ovf.f90`.

When the program is compiled at a higher optimization level of `O2`, along with `-fpe 0` (Linux OS and Mac OS X) or `/fpe:0` (Windows) and `-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS), the traceback output appears as follows:

```
forrtl: error (72): floating overflow
Image              PC        Routine        Line       Source
ovf.exe            00401070  OVF                29    ovf.f90
ovf.exe            004323E9  Unknown        Unknown    Unknown
ovf.exe            00426C34  Unknown        Unknown    Unknown
KERNEL32.dll       77F1B9EA  Unknown        Unknown    Unknown
```

With `/O2`, the entire program has been inlined.

The main program, `OVF`, no longer calls routine `HEY`. While the output is not quite what one might have expected intuitively, it is still entirely correct. You need to keep in mind the effects of compiler optimization when you interpret the diagnostic information reported for a failure in a release image.

If the same image were executed again, this time with the environment variable called `TBK_ENABLE_VERBOSE_STACK_TRACE` set to True, you would also see a dump of the exception context record at the time of the error. Here is an excerpt of how that might appear on a system using IA-32 architecture:

```
forrtl: error (72): floating overflow
Hex Dump Of Exception Record Context Information:

```

Example: Using Traceback in Mixed Fortran/C Applications, Program FPING and CPONG

Consider the following example that shows how the traceback output might appear in a mixed Fortran/C application. The main program is a Fortran program named `FPING`. Program `FPING` triggers a chain of function calls which are alternately Fortran and C code. Eventually, the C routine named Unlucky is called, which produces a floating divide-by-zero error.

Source module `FPING.FOR` contains the Fortran function definitions, each of which calls a C routine from source module `CPONG.C`. The program `FPING.FOR` is compiled with the following options:

- `-fpe 0` (Linux OS and Mac OS X) or `/fpe:0` (Windows OS)
- `-traceback` (Linux OS and Mac OS X) or `/traceback` (Windows OS)
- `-O0` (Linux OS and Mac OS X) or `/Od` (Windows OS)

On the IA-32 architecture platform. the program traceback output resembles the following:

```
forrtl: error (73): floating divide by zero
Image              PC        Routine       Line     Source
fping.exe          00401161  Unknown       Unknown  Unknown
fping.exe          004010DC  DOWN4              58  fping.for
fping.exe          0040118F  Unknown       Unknown  Unknown
fping.exe          004010B6  DOWN3              44  fping.for
fping.exe          00401181  Unknown       Unknown  Unknown
fping.exe          00401094  DOWN2              31  fping.for
fping.exe          00401173  Unknown       Unknown  Unknown
fping.exe          00401072  DOWN1              18  fping.for
fping.exe          0040104B  FPING               5  fping.for
fping.exe          004013B9  Unknown       Unknown  Unknown
fping.exe          004012AF  Unknown       Unknown  Unknown
KERNEL32.dll       77F1B304  Unknown       Unknown  Unknown
```

Notice that the stack frames contributed by Fortran routines can be correlated to a routine name, line number, and source module but those frames contributed by C routines cannot be correlated. Remember, even though the stack can be walked in reverse, and PCs reported, the information necessary to correlate the PC to a routine name, line number, and so on, is contributed to the image from the objects generated by the Fortran compiler. The C compiler does not have this capability. Also remember that you only get the correlation information if you specify the `-traceback` or `/traceback` option for your Fortran compiles.

The top stack frame cannot be correlated to a routine name because it is in C code. You can examine the map file for the application; if you do so, you will see that the reported PC, 00401161, is greater than the start of routine _Unlucky, but less than the start of routine _down1_C. This means that the error occurred in routine _Unlucky.

In a similar manner, the other PCs reported as "Unknown" can be correlated to a routine name using the map file.

When examining traceback output (or any type of diagnostic output, for that matter), it is important to keep in mind the effects of compiler optimization. The Fortran source module in the above example was built with optimization turned off. Look at the output when optimizations are enabled with `-O2` (Linux OS and Mac OS X) or `/O2` (Windows OS):

```
forrtl: error (73): floating divide by zero
Image              PC        Routine     Line     Source
fping.exe          00401111  Unknown     Unknown  Unknown
fping.exe          0040109D  DOWN4            58  fping.for
fping.exe          0040113F  Unknown     Unknown  Unknown
fping.exe          00401082  DOWN3            44  fping.for
fping.exe          00401131  Unknown     Unknown  Unknown
fping.exe          0040106B  DOWN2            31  fping.for
fping.exe          00401123  Unknown     Unknown  Unknown
fping.exe          00401032  FPING            18  fping.for
fping.exe          00401369  Unknown     Unknown  Unknown
fping.exe          0040125F  Unknown     Unknown  Unknown
KERNEL32.dll       77F1B304  Unknown     Unknown  Unknown
```

From the traceback output, it would appear that routine DOWN1 was never called. In fact, it has not been called. At the higher optimization level, the compiler has inlined function DOWN1 so that the call to routine down1_C is now made from FPING. The correlated line number still points to the correct line in the source code.

Finally, suppose the example Fortran code is redesigned with each of the Fortran routines split into separate source modules. Here is what the traceback output would look like with the redesigned code:

```
forrtl: error (73): floating divide by zero
Image              PC        Routine      Line     Source
fpingmain.exe      00401171  Unknown      Unknown  Unknown
```

```
fpingmain.exe    004010ED  DOWN4            12  fping4.for
fpingmain.exe    0040119F  Unknown      Unknown  Unknown
fpingmain.exe    004010C1  DOWN3            11  fping3.for
fpingmain.exe    00401191  Unknown      Unknown  Unknown
fpingmain.exe    00401099  DOWN2            11  fping2.for
fpingmain.exe    00401183  Unknown      Unknown  Unknown
fpingmain.exe    00401073  DOWN1            11  fping1.for
fpingmain.exe    0040104B  FPING             5  fpingmain.for
fpingmain.exe    004013C9  Unknown      Unknown  Unknown
fpingmain.exe    004012BF  Unknown      Unknown  Unknown
KERNEL32.dll     77F1B304  Unknown      Unknown  Unknown
```

Notice that the line number and source file correlation information has changed to reflect the new design of the code.

Here are the sources used in the above examples:

Obtaining Traceback Information with TRACEBACKQQ

You can obtain traceback information in your application by calling the TRACEBACKQQ routine.

`TRACEBACKQQ` allows an application to initiate a stack trace. You can use this routine to report application detected errors, use it for debugging, and so on. It uses the standard stack trace support in the Intel® Fortran run-time system to produce the same output that the run-time system produces for unhandled errors and exceptions (severe error message). The `TRACEBACKQQ` subroutine generates a stack trace showing the program call stack as it was leading up to the point of the call to `TRACEBACKQQ`.

The error message string normally included from the run-time support is replaced with the user-supplied message text or omitted if no user string is specified. Traceback output is directed to the target destination appropriate for the application type, just as it is when traceback is initiated internally by the run-time support.

In the most simple case, a user can generate a stack trace by coding the call to TRACEBACKQQ with no arguments:

```
CALL TRACEBACKQQ()
```

This call causes the run-time library to generate a traceback report with no leading header message, from wherever the call site is, and terminate execution.

You can specify arguments that generate a stack trace with the user-supplied string as the header and instead of terminating execution, return control to the caller to continue execution of the application. For example:

```
CALL TRACEBACKQQ(STRING="Done with pass 1",USER_EXIT_CODE=-1)
```

By specifying a user exit code of -1, control returns to the calling program. Specifying a user exit code with a positive value requests that specified value be returned to the operating system. The default value is 0, which causes the application to abort execution.

Portability Considerations 16

Portability Considerations Overview

This section presents topics to help you understand how language standards, operating system differences, and computing hardware influence your use of Intel® Fortran and the portability of your programs.

Your program is portable if you can implement it on one hardware-software platform and then move it to additional systems with a minimum of changes to the source code. Correct results on the first system should be correct on the additional systems. The number of changes you might have to make when moving your program varies significantly. You might have no changes at all (strictly portable), or so many (non-portable customization) that it is more efficient to design or implement a new program. Most programs in their lifetime will need to be ported from one system to another, and this section can help you write code that makes this easy.

Understanding Fortran Language Standards

Understanding Fortran Language Standards Overview

A language standard specifies the form and establishes the interpretation of programs expressed in the language. Its primary purpose is to promote, among vendors and users, portability of programs across a variety of systems.

The vendor-user community has adopted four major Fortran language standards. ANSI (American National Standards Institute) and ISO (International Standards Organization) are the primary organizations that develop and publish the standards.

The major Fortran language standards are:

- FORTRAN IV

American National Standard Programming Language FORTRAN, ANSI X3.9-1966. This was the first attempt to standardize the languages called FORTRAN by many vendors.

- FORTRAN 77

  American National Standard Programming Language FORTRAN, ANSI X3.9-1978. This standard added new features based on vendor extensions to FORTRAN IV and addressed problems associated with large-scale projects, such as improved control structures.

- Fortran 90

  American National Standard Programming Language Fortran, ANSI X3.198-1992 and International Standards Organization, ISO/IEC 1539: 1991, Information technology -- Programming languages -- Fortran. This standard emphasizes modernization of the language by introducing new developments. For information about differences between Fortran 90 and FORTRAN 77, see the *Fortran Language Reference Manual*.

- Fortran 95

  American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1: 1997(E), Information technology -- Programming languages -- Fortran. This standard introduces certain language elements and corrections into Fortran 90. Fortran 95 includes Fortran 90 and most features of FORTRAN 77. For information about differences between Fortran 95 and Fortran 90, see the *Fortran Language Reference Manual*.

- Fortran 2003

  American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1:2004, Information technology -- Programming languages -- Fortran. This standard introduces extended support for exception handling, object-oriented programming, and improved interoperability with the C language. For more information on supported Fortran 2003 features, see the Fortran Language Reference Manual.

Although a language standard seeks to define the form and the interpretation uniquely, a standard may not cover all areas of interpretation. It may also include some ambiguities. You need to carefully craft your program in these cases so that you get the answers that you want when producing a portable program.

Using Standard Features and Extensions

Use standard features to achieve the greatest degree of portability for your Intel Fortran programs. You can design a robust implementation to improve the portability of your program, or you can choose to use extensions to the standard to increase the readability, functionality, and efficiency of your programs. You can ensure your program enforces the Fortran standard by using the `-stand` (Linux* OS and Mac OS* X) or `/stand` (Windows* OS) compiler option with the appropriate keyword (`f90`, `f95`, or `f03`) to flag extensions. The `none` keyword turns

off enforcement of a particular Fortran standard. You can also use the following compiler options to set the Fortran standard: `-std90` or `/std90`, `-std95` or `/std95`, and `-std03` or `/std03`. The default is std03, which diagnoses exceptions to the Fortran 2003 standard.

Not all Fortran standard extensions cause problems when porting to other platforms. Many extensions are supported on a wide range of platforms, and if a system you are porting a program to supports an extension, there is no reason to avoid using it. There is no guarantee, however, that the same feature on another system will be implemented in the same way as it is in Intel Fortran. Only the Fortran standard is guaranteed to coexist uniformly on all platforms.

Intel® Fortran supports many language extensions on multiple platforms, including Windows, Linux, and Mac OS X operating systems. The Intel® *Fortran Language Reference Manual* identifies whether each language element is supported on other platforms.

It is a good programming practice to declare any external procedures either in an EXTERNAL statement or in a procedure interface block, for the following reasons:

- The Fortran 90 standard added many new intrinsic procedures to the language. Programs that conformed to the FORTRAN 77 standard may include nonintrinsic functions or subroutines having the same name as new Fortran 90 procedures.
- Some processors include nonstandard intrinsic procedures that might conflict with procedure names in your program.

If you do not explicitly declare the external procedures and the name duplicates an intrinsic procedure, the processor calls the intrinsic procedure, not your external routine. For more information on how the Fortran compiler resolves name definitions, see Resolving Procedure References.

Using Compiler Optimizations

Many Fortran compilers perform code-generation optimizations to increase the speed of execution or to decrease the required amount of memory for the generated code. Although the behaviors of both the optimized and nonoptimized programs fall within the language standard specification, different behaviors can occur in areas not covered by the language standard. Compiler optimization especially can influence floating-point numeric results.

The Intel® Fortran compiler can perform optimizations to increase execution speed and to improve floating-point numerical consistency.

Floating-point consistency refers to obtaining results consistent with the IEEE binary floating-point standards. For more information, see the `-fltconsistency` (Linux OS and Mac OS X) or `/fltconsistency` (Windows OS) option.

Unless you properly design your code, you may encounter numerical difficulties when you optimize for fastest execution. The `-nofltconsistency` or `/nofltconsistency` option uses the floating-point registers, which have a higher precision than stored variables, whenever possible. This tends to produce results that are inconsistent with the precision of stored variables.

The `-fltconsistency` or `/fltconsistency` option can improve the consistency of generated code by rounding results of statement evaluations to the precision of the standard data types, but it does produce slower execution times.

See also Optimizing Applications.

Minimizing Operating System-Specific Information

The operating system influences your program both externally and internally. For increased portability, you need to minimize the amount of operating-system-specific information required by your program. The Fortran language standards do not specify this information.

Operating-system-specific information consists of nonintrinsic extensions to the language, compiler and linker options, and possibly the graphical user interface of Windows. Input and output operations use devices that may be system-specific, and may involve a file system with system-specific record and file structures.

The operating system also governs resource management and error handling. You can depend on default resource management and error handling mechanisms or provide mechanisms of your own. For information on special library routines to help port your program from one system to another, see Portability Library Overview and related topics.

The minimal interaction with the operating system is for input/output (I/O) operations and usually consists of knowing the standard units preconnected for input and output. You can use default file units with the asterisk (*) unit specifier.

To increase the portability of your programs across operating systems, consider the following:

- Do not assume the use of a particular type of file system.
- Do not embed filenames or paths in the body of your program. Define them as constants at the beginning of the program or read them from input data.
- Do not assume a particular type of standard I/O device or the "size" of that device (number of rows and columns).
- Do not assume display attributes for the standard I/O device. Some environments do not support attributes such as color, underlined text, blinking text, highlighted text, inverse text, protected text, or dim text.

Storing and Representing Data

The Fortran language standard specifies little about the storage of data types.

This loose specification of storage for data types results from a great diversity of computing hardware. This diversity poses problems in representing data and especially in transporting stored data among a multitude of systems. The size (as measured by the number of bits) of a

storage unit (a word, usually several bytes) varies from machine to machine. In addition, the ordering of bits within bytes and bytes within words varies from one machine to another. Furthermore, binary representations of negative integers and floating-point representations of real and complex numbers take several different forms.

If you are careful, you can avoid most of the problems involving data storage. The simplest and most reliable means of transferring data between dissimilar systems is in *character* and not binary form. Simple programming practices ensure that your data as well as your program is portable.

See also Supported Native and Nonnative Numeric Formats.

Formatting Data for Transportability

You can achieve the highest transportability of your data by formatting it as 8-bit character data. Use a standard character set such as the ASCII standard for encoding your character data. Although this practice is less efficient than using binary data, it will save you from shuffling and converting your data.

If you are transporting your data by means of a record-structured medium, it is best to use the Fortran sequential formatted (as character data) form. You can also use the direct formatted form, but you need to know the record length of your data.

Remember also that some systems use a carriage return/linefeed pair as an end-of-record indicator, while other systems use linefeed only. If you use either the direct unformatted or the sequential unformatted form, there might be system-dependent values embedded within your data that complicate its transport.

Implementing a strictly portable solution requires a careful effort. Maximizing portability may also mean making compromises to the efficiency and functionality of your solution. If portability is not your highest priority, you can use some of the techniques that appear in later sections to ease your task of customizing a solution.

Troubleshooting

17

Troubleshooting Your Application

The following lists some of the most basic problems you can encounter during application development and gives suggestions for troubleshooting:

- Source code does not compile correctly.

  If your source code fails to compile, check for unsupported language extensions. Typically, these produce a syntax error. The best way to resolve problems of this nature is to rewrite the source code so it conforms to the supported Fortran standards and does not contain unsupported extensions.

- Program does not run produce expected results.

  Use test scenarios that ensure the output matches your expectations. If a test fails, try compiling the files using the `-O0` (Linux* OS and Mac OS* X) or `/Od` (Windows* OS) option, which turns off the optimizer. If the test still fails, it is likely that the source code contains a problem. If your program runs successfully with `-O0` (Linux OS and Mac OS X) or `/Od` (Windows OS), but fails with the default `-O2` (Linux OS and Mac OS X) or `/O2` (Windows OS), you need to determine which file or files are causing the problem.

- Program runs slowly.

  Try to determine where your program spends most of its time. Such an analysis will show you which lines of your program are using the most execution time. See the Optimizing Applications book for additional guidelines that will help you optimize performance and gain speed.

Reference Information

18

Key Compiler Files Summary

The following table lists the key files that are installed for use by the compiler.

\bin Files	
File	**Description**
`codecov`	Executable for the Code-coverage tool
`fortcom`	Executable used by the compiler
`fpp`	Fortran preprocessor
`ias` (Linux* OS and Mac OS* X)	Assembler for systems using IA-64 architecture
`idis` (Windows* OS)	Disassembler for systems using IA-64 architecture
`ifortvars`	File to set environment variables
`ifort.cfg`	Configuration file for use from command line
`ifort`	Intel® Fortran Compiler
`ifortbin` (Linux OS and Mac OS X)	Executable used by the compiler
`map_opts`	Utility used for option translation
`profmerge`	Utility used for Profile Guided Optimizations
`proforder`	Utility used for Profile Guided Optimizations
`tselect`	Test prioritization tool
`uninstall.sh` (Linux OS and Mac OS X)	Uninstall utility
`xiar` (Linux OS)	Tool used for Interprocedural Optimizations

\bin Files	
File	**Description**
`xilibtool` (Mac OS X) `xilib` (Windows OS)	
`xild` (Linux OS and Mac OS X) `xilink` (Windows OS)	Tool used for Interprocedural Optimizations

For a list of the files installed in the `lib` directory, see Supplied Libraries.

Compiler Limits

The amount of data storage, the size of arrays, and the total size of executable programs are limited only by the amount of process virtual address space available, as determined by system parameters.

The table below shows the limits to the size and complexity of a single Intel® Fortran program unit and to individual statements contained within it:

Language Element	Limit
Actual number of arguments per CALL or function reference	Limited only by memory constraints
Arguments in a function reference in a specification expression	255
Array dimensions	7
Array elements per dimension	9,223,372,036,854,775,807 = 2**31-1 on systems using IA-32 architecture; 2**63-1 on systems using Intel® 64 and IA-64 architectures; plus limited by current memory configuration
Constants: character and Hollerith	7198
Constants: characters read in list-directed I/O	2048 characters

Language Element	Limit
Continuation lines - free form	Depends on line complexity and the number of lexical tokens allowed.
Continuation lines - fixed form	Depends on line complexity and the number of lexical tokens allowed.
Data and I/O implied DO nesting	7
DO and block IF statement nesting (combined)	256
DO loop index variable	9,223,372,036,854,775,807= 2**63-1
Format group nesting	8
Fortran statement length	2048 characters
Fortran source line length	fixed form: 72 (or 132 if `/extend_source` is in effect) characters; free form: 7200 characters
INCLUDE file nesting	20 levels
Labels in computed or assigned GOTO list	Limited only by memory constraints
Lexical tokens per statement	40000
Named common blocks	Limited only by memory constraints
Nesting of array constructor implied DOs	7
Nesting of input/output implied DOs	7
Nesting of interface blocks	Limited only by memory constraints
Nesting of DO, IF, or CASE constructs	Limited only by memory constraints
Nesting of parenthesized formats	Limited only by memory constraints
Number of arguments to MIN and MAX	Limited only by memory constraints
Number of digits in a numeric constant	Limited by statement length

Language Element	Limit
Parentheses nesting in expressions	Limited only by memory constraints
Structure nesting	30
Symbolic name length	63 characters
Width field for a numeric edit descriptor	2**31 - 1

See the product Release Notes for more information on memory limits for large data objects.

- Quick Reference Guides and Cross References
- Related Options

Overview: Compiler Options

19

This document provides details on all current Linux* OS, Mac OS* X, and Windows* OS compiler options.

It provides the following information:

- New options
  This topic lists new compiler options in this release.
- Deprecated
  This topic lists deprecated and removed compiler options for this release. Some deprecated options show suggested replacement options.
- Alphabetical Compiler Options
  This topic is the main source in the documentation set for general information on all compiler options. Options are described in alphabetical order. The Overview describes what information appears in each compiler option description.
- Quick Reference Guide and Cross Reference
  This topic contains tables summarizing compiler options. The tables show the option name, a short description of the option, the default setting for the option, and the equivalent option on the operating system, if any.
- Related Options
  This topic lists related options that can be used under certain conditions.

In this guide, compiler options are available on all supported operating systems and architectures unless otherwise identified.

For further information on compiler options, see Building Applications and Optimizing Applications.

Functional Groupings of Compiler Options

To see functional groupings of compiler options, specify a functional category for option `help` on the command line. For example, to see a list of options that affect diagnostic messages displayed by the compiler, enter one of the following commands:

```
-help diagnostics     ! Linux and Mac OS X systems

/help diagnostics     ! Windows systems
```

For details on the categories you can specify, see help.

New Options

This topic lists the options that provide new functionality in this release.

Some compiler options are only available on certain systems, as indicated by these labels:

Label	Meaning
i32	The option is available on systems using IA-32 architecture.
i64em	The option is available on systems using Intel® 64 architecture.
i64	The option is available on systems using IA-64 architecture.

If no label appears, the option is available on all supported systems.

If "only" appears in the label, the option is only available on the identified system.

For more details on the options, refer to the Alphabetical Compiler Options section.

For information on conventions used in this table, see Conventions.

New compiler options are listed in tables below:

- The first table lists new options that are available on Windows* systems.
- The second table lists new options that are available on Linux* and Mac OS* X systems. If an option is only available on one of these operating systems, it is labeled.

Windows* OS Options	Description	Default
`/arch:IA32` (i32 only)	Generates code that will run on any Pentium or later processor.	OFF
`/arch:SSE3` (i32, i64em)	Optimizes for Intel® Streaming SIMD Extensions 3 (Intel® SSE3).	OFF
`/arch:SSSE3` (i32, i64em)	Optimizes for Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3).	OFF
`/arch:SSE4.1` (i32, i64em)	Optimizes for Intel® Streaming SIMD Extensions 4 Vectorizing Compiler and Media Accelerators.	OFF

Windows* OS Options	Description	Default
/assume:[no]ieee_fpe_flags	Determines whether the floating-point exception and status flags are saved on routine entry and restored on routine exit.	OFF
/assume:[no]old_logical_ldio	Determines whether NAMELIST and list-directed input accept logical values for numeric IO-list items.	ON
/assume:[no]old_maxminloc	Determines the results of the intrinsics MAXLOC and MINLOC when given an empty array as an argument.	ON
/debug:[no]parallel(i32, i64em)	Generates parallel debug code instrumentations needed for the thread data sharing and reentrant call detection of the Intel® Parallel Debugger Extension.	OFF
/fpe-all:n	Allows some control over floating-point exception handling for each routine in a program at run-time.	/fpe-all:3
/GS (i32, i64em)	Determines whether the compiler generates code that detects some buffer overruns.	/GS-
/homeparams	Tells the compiler to store parameters passed in registers to the stack.	OFF
/hotpatch (i32, i64em)	Tells the compiler to prepare a routine for hotpatching	OFF
/QaxSSE2 (i32, i64em)	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2.	OFF
/QaxSSE3 (i32, i64em)	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture.	OFF

Windows* OS Options	Description	Default
/QaxSSSE3 (i32, i64em)	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family.	OFF
/QaxSSE4.1 (i32, i64em)	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture.	OFF
/QaxSSE4.2 (i32, i64em)	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.	OFF
/Qdiag-enable:sc-parallel (i32, i64em)	Enables analysis of parallelization in source code (parallel lint diagnostics).	OFF
/Qdiag-error-limit:n	Specifies the maximum number of errors allowed before compilation stops.	n=30
/Qdiag-once:id[,id,...]	Tells the compiler to issue one or more diagnostic messages only once.	OFF
/Qdiag-error-limit:n	Specifies the maximum number of errors allowed before compilation stops.	n=30
/Qdiag-once:id[,id,...]	Tells the compiler to issue one or more diagnostic messages only once.	OFF
/Qfast-transcendentals	Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.	OFF

Windows* OS Options	Description	Default
/Qfma (i64 only)	Enables the combining of floating-point multiplies and add/subtract operations.	ON
/Qfp-relaxed (i64 only)	Enables use of faster but slightly less accurate code sequences for math functions.	OFF
/Qinstruction:[no]movbe (i32, i64em)	Determines whether MOVBE instructions are generated for Intel processors.	OFF
/Qimsl	Tells the compiler to link to the IMSL* library.	OFF
/Qmkl	Tells the compiler to link to certain parts of the Intel® Math Kernel Library.	OFF
/Qopenmp-link:library	Controls whether the compiler links to static or dynamic OpenMP run-time libraries.	/Qopenmp-link:dynamic
/Qopenmp-threadprivate:type	Lets you specify an OpenMP* threadprivate implementation.	/Qopenmp-threadprivate:legacy
/Qopt-block-factor:n	Lets you specify a loop blocking factor.	OFF
/Qopt-jump-tables:keyword	Enables or disables generation of jump tables for switch statements.	/Qopt-jump-tables:default
/Qopt-loadpair (i64 only)	Enables loadpair optimization.	/Qopt-loadpair-
/Qopt-mod-versioning (i64 only)	Enables versioning of modulo operations for certain types of operands.	/Qopt-mod-versioning-

Windows* OS Options	Description	Default
/Qopt-prefetch-initial-values (i64 only)	Enables or disables prefetches that are issued before a loop is entered.	/Qopt-prefetch-initial-values
/Qopt-prefetch-issue-excl-hint (i64 only)	Determines whether the compiler issues prefetches for stores with exclusive hint.	/Qopt-prefetch-issue-excl-hint-
/Qopt-prefetch-next-iteration (i64 only)	Enables or disables prefetches for a memory access in the next iteration of a loop.	/Qopt-prefetch-next-iteration
/Qopt-subscript-in-range (i32, i64em)	Determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.	/Qopt-subscript-in-range-
/Qpar-affinity:[modifier,...]type[,permute][,offset]	Specifies thread affinity.	OFF
/Qpar-num-threads:n	Specifies the number of threads to use in a parallel region.	OFF
/Qprof-data-order	Enables or disables data ordering if profiling information is enabled.	/Qprof-data-order
/Qprof-func-order	Enables or disables function ordering if profiling information is enabled.	/Qprof-func-order

Windows* OS Options	Description	Default
/Qprof-hot-ness-thresh-old	Lets you set the hotness threshold for function grouping and function ordering.	OFF
/Qprof-src-dir	Determines whether directory information of the source file under compilation is considered when looking up profile data records.	/Qprof-src-dir
/Qprof-src-root	Lets you use relative directory paths when looking up profile data and specifies a directory as the base.	OFF
/Qprof-src-root-cwd	Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.	OFF
/Qtcollect-filter	Lets you enable or disable the instrumentation of specified functions.	OFF
/Quse-msasm-symbols (i32, i64em)	Tells the compiler to use a dollar sign ("$") when producing symbol names.	OFF
/Qvc9 (i32, i64em)	Specifies compatibility with Microsoft* Visual Studio 2008.	varies
/Qvec (i32, i64em)	Enables or disables vectorization and transformations enabled for vectorization.	/Qvec
/Qvec-thresh-old (i32, i64em)	Sets a threshold for the vectorization of loops.	/Qvec-thresh-old100
/QxHost (i32, i64em)	Can generate instructions for the highest instruction set available on the compilation host processor.	OFF
/QxAVX (i32, i64em)	Optimizes for Intel processors that support Intel® Advanced Vector Extensions (Intel® AVX).	OFF

Windows* OS Options	Description	Default
/QxSSE2 (i32, i64em)	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2.	ON
/QxSSE3 (i32, i64em)	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors, and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture.	OFF
/QxSSE3_ATOM (i32, i64em)	Optimizes for the Intel® Atom™ processor and Intel® Centrino® Atom™ Processor Technology.	OFF
/QxSSSE3 (i32, i64em)	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family.	OFF
/QxSSE4.1 (i32, i64em)	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture.	OFF
/QxSSE4.2 (i32, i64em)	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.	OFF

Linux* OS and Mac OS* X Options	Description	Default
-assume [no]ieee_fpe_flags	Determines whether the floating-point exception and status flags are saved on routine entry and restored on routine exit.	OFF

Linux* OS and Mac OS* X Options	Description	Default
`-assume [no]old_logical_ldio`	Determines whether NAMELIST and list-directed input accept logical values for numeric IO-list items.	ON
`-assume [no]old_maxminloc`	Determines the results of the intrinsics MAXLOC and MINLOC when given an empty array as an argument.	ON
`-axSSE2` (i32, i64em; Linux only)	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2.	OFF
`-axSSE3` (i32, i64em)	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors, and it can optimize for processors based on Intel® Core microarchitecture and Intel NetBurst® microarchitecture. On Mac OS* X systems, this option is only available on IA-32 architecture.	OFF
`-axSSSE3` (i32, i64em)	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. On Mac OS* X systems, this option is only available on Intel® 64 architecture.	OFF
`-axSSE4.1` (i32, i64em)	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture.	OFF
`-axSSE4.2` (i32, i64em)	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4	OFF

Linux* OS and Mac OS* X Options	Description	Default
	Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.	
`-diag-enable sc-parallel` (i32, i64em)	Enables analysis of parallelization in source code (parallel lint diagnostics).	OFF
`-diag-error-limit n`	Specifies the maximum number of errors allowed before compilation stops.	n=30
`-diag-once id[,id,...]`	Tells the compiler to issue one or more diagnostic messages only once.	OFF
`-falign-stack` (i32 only)	Tells the compiler the stack alignment to use on entry to routines.	`-falign-stack=default`
`-fast-tran-scendentals`	Enables the compiler to replace calls to transcendental functions with faster but less precise implementation.	OFF
`-finline`	Tells the compiler to inline functions declared with cDEC$ ATTRIBUTES FORCEINLINE.	`-fno-inline`
`-fma` (i64 only; Linux* OS only)	Enables the combining of floating-point multiplies and add/subtract operations.	ON
`-fp-relaxed` (i64 only; Linux* OS only)	Enables use of faster but slightly less accurate code sequences for math functions.	OFF
`-fpe-all=n`	Allows some control over floating-point exception handling for each routine in a program at run-time.	`-fpe-all=3`
`-fpie` (Linux* OS only)	Tells the compiler to generate position-independent code to link into executables.	OFF

Linux* OS and Mac OS* X Options	Description	Default
-fstack-protector (i32, i64em)	Determines whether the compiler generates code that detects some buffer overruns. Same as option -fstack-security-check.	-fno-stack-protector
-fstack-security-check (i32, i64em)	Determines whether the compiler generates code that detects some buffer overruns.	-fno-stack-security-check
-m32, -m64 (i32, i64em)	Tells the compiler to generate code for a specific architecture.	OFF
-mia32 (i32 only)	Generates code that will run on any Pentium or later processor.	OFF
-minstruction=[no]movbe (i32, i64em)	Determines whether MOVBE instructions are generated for Intel processors.	OFF
-mkl	Tells the compiler to link to certain parts of the Intel® Math Kernel Library.	OFF
-mssse3 (i32, i64em)	Generates code for Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3).	Linux systems: OFF Mac OS X systems using Intel® 64 architecture: ON
-msse4.1 (i32, i64em)	Generates code for Intel® Streaming SIMD Extensions 4 Vectorizing Compiler and Media Accelerators.	OFF
-openmp-link library	Controls whether the compiler links to static or dynamic OpenMP run-time libraries.	-openmp-link dynamic
-openmp-threadprivate=type	Lets you specify an OpenMP* threadprivate implementation.	-openmp-threadprivate=legacy

Linux* OS and Mac OS* X Options	Description	Default
(Linux* OS only)		
-opt-block-factor=n	Lets you specify a loop blocking factor.	OFF
-opt-jump-tables=keyword	Enables or disables generation of jump tables for switch statements.	-opt-jump-tables=default
-opt-loadpair (i64 only; Linux* OS only)	Enables loadpair optimization.	-no-opt-load-pair
-opt-mod-versioning (i64 only; Linux* OS only)	Enables versioning of modulo operations for certain types of operands.	-no-opt-mod-versioning
-opt-prefetch-initial-values (i64 only; Linux* OS only)	Enables or disables prefetches that are issued before a loop is entered.	-opt-prefetch-initial-values
-opt-prefetch-issue-excl-hint (i64 only)	Determines whether the compiler issues prefetches for stores with exclusive hint.	-no-opt-prefetch-issue-excl-hint
-opt-prefetch-next-iteration (i64 only; Linux* OS only)	Enables or disables prefetches for a memory access in the next iteration of a loop.	-opt-prefetch-next-iteration

Linux* OS and Mac OS* X Options	Description	Default
-opt-sub-script-in-range (i32, i64em)	Determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.	-no-opt-sub-script-in-range
-par-affinity=[modifier,...]type[,permute][,offset] (Linux* OS only)	Specifies thread affinity.	OFF
-par-num-threads=n	Specifies the number of threads to use in a parallel region.	OFF
-pie (Linux* OS only)	Produces a position-independent executable on processors that support it.	OFF
-prof-data-order (Linux* OS only)	Enables or disables data ordering if profiling information is enabled.	-no-prof-data-order
-prof-func-groups (i32, i64em; Linux* OS only)	Enables or disables function grouping if profiling information is enabled.	-no-prof-func-groups
-prof-func-order (Linux* OS only)	Enables or disables function ordering if profiling information is enabled.	-no-prof-func-order
-prof-hotness-threshold (Linux* OS only)	Lets you set the hotness threshold for function grouping and function ordering.	OFF

Linux* OS and Mac OS* X Options	Description	Default
-prof-src-root	Lets you use relative directory paths when looking up profile data and specifies a directory as the base.	OFF
-prof-src-root-cwd	Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.	OFF
-staticlib (i32, i64em; Mac OS* X only)	Invokes the libtool command to generate static libraries.	OFF
-tcollect-filter (Linux* OS only)	Lets you enable or disable the instrumentation of specified functions.	OFF
-vec (i32, i64em)	Enables or disables vectorization and transformations enabled for vectorization.	-vec
-vec-threshold (i32, i64em)	Sets a threshold for the vectorization of loops.	-vec-threshold100
-xHost (i32, i64em)	Can generate instructions for the highest instruction set available on the compilation host processor.	OFF
-xAVX (i32, i64em)	Optimizes for Intel processors that support Intel® Advanced Vector Extensions (Intel® AVX).	OFF
-xSSE2 (i32, i64em; Linux only)	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2.	ON

Linux* OS and Mac OS* X Options	Description	Default
-xSSE3 (i32, i64em)	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. On Mac OS* X systems, this option is only available on IA-32 architecture.	Linux systems:OFF Mac OS X systems using IA-32 architecture: ON
-xSSE3_ATOM (i32, i64em)	Optimizes for the Intel® Atom™ processor and Intel® Centrino® Atom™ Processor Technology.	OFF
-xSSSE3 (i32, i64em)	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. On Mac OS* X systems, this option is only available on Intel® 64 architecture.	Linux systems:OFF Mac OS X systems using Intel® 64 architecture: ON
-xSSE4.1 (i32, i64em)	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture.	OFF
-xSSE4.2 (i32, i64em)	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.	OFF

Deprecated and Removed Compiler Options

This topic lists deprecated and removed compiler options and suggests replacement options, if any are available.

Deprecated Options

Occasionally, compiler options are marked as "deprecated." Deprecated options are still supported in the current release, but are planned to be unsupported in future releases.

The following options are deprecated in this release of the compiler:

Linux* OS and Mac OS* X Options	Suggested Replacement
`-axK`	None
`-axN`	Linux* OS: `-axSSE2` Mac OS* X: None
`-axP`	Linux* OS: `-axSSE3` Mac OS* X on IA-32 architecture: `-axSSE3` Mac OS* X on Intel® 64 architecture: None
`-axS`	`-axSSE4.1`
`-axT`	Linux* OS: `-axSSSE3` Mac OS* X on IA-32 architecture: None Mac OS* X on Intel® 64 architecture: `-axSSSE3`
`-axW`	`-msse2`
`-diag-<type> sv[<n>]`	`-diag-<type> sc[<n>]`
`-diag-enable sv-include`	`-diag-enable sc-include`
`-func-groups`	`-prof-func-groups`
`-i-dynamic`	`-shared-intel`
`-i-static`	`-static-intel`
`-inline-debug-info`	`-debug`
`-IPF-flt-eval-method0`	`-fp-model source`

Linux* OS and Mac OS* X Options	Suggested Replacement
-IPF-fltacc -no-IPF-fltacc	-fp-model precise -fp-model fast
-IPF-fma	-fma
-IPF-fp-relaxed	-fp-relaxed
-march=pentiumii	None
-march=pentiumiii	-march=pentium3
-mcpu	-mtune
-mp	-fp-model
-Ob	-inline-level
-openmp-lib legacy	None
-openmpP	-openmp
-openmpS	-openmp-stubs
-prefetch	-opt-prefetch
-prof-genx	-prof-gen=srcpos
-use-asm	None
-use-pch	-pch-use
-xK	-mia32
-xN	Linux* OS: -xSSE2 Mac OS* X: None
-xO	-msse3

Linux* OS and Mac OS* X Options	Suggested Replacement
-xP	Linux* OS: -xSSE3 Mac OS* X on IA-32 architecture: -xSSE3 Mac OS* X on Intel® 64 architecture: None
-xS	-xSSE4.1
-xT	Linux* OS: -xSSSE3 Mac OS* X on IA-32 architecture: None Mac OS* X on Intel® 64 architecture: -xSSSE3
-xW	-msse2

Windows* OS Options	Suggested Replacement
/4Nb	/check:none
/4Yb	/check:all
/debug:partial	None
/Fm	/map
/G5	None
/G6 (or /GB)	None
/G7	None
/Ge	/Gs0
/ML and/MLd	None
/Op	/fp
/QaxK	None
/QaxN	/QaxSSE2

Windows* OS Options	Suggested Replacement
/QaxP	/QaxSSE3
/QaxS	/QaxSSE4.1
/QaxT	/QaxSSSE3
/QaxW	/arch:SSE2
/Qdiag-<type> sv[<n>]	/Qdiag-<type> sc[<n>]
/Qdiag-enable:sv-include	/Qdiag-enable:sc-include
/Qinline-debug-info	None
/QIPF-flt-eval-method0	/fp:source
/QIPF-fltacc /QIPF-fltacc-	/fp:precise /fp:fast
/QIPF-fma	/Qfma
/QIPF-fp-relaxed	/Qfp-relaxed
/Qopenmp-lib:legacy	None
/Qprefetch	/Qopt-prefetch
/Qprof-genx	/Qprof-gen=srcpos
/Quse-asm	None
/Quse-vcdebug	None
/QxK	None
/QxN	/QxSSE2
/QxO	/arch:SSE3

Windows* OS Options	Suggested Replacement
/QxP	/QxSSE3
/QxS	/QxSSE4.1
/QxT	/QxSSSE3
/QxW	/arch:SSE2
/Zd	/debug:minimal

Deprecated options are not limited to this list.

Removed Options

Some compiler options are no longer supported and have been removed. If you use one of these options, the compiler issues a warning, ignores the option, and then proceeds with compilation.

This version of the compiler no longer supports the following compiler options:

Linux* OS and Mac OS* X Options	Suggested Replacement
-axB	-axSSE2
-axi	None
-axM	None
-cxxlib-gcc[=dir]	-cxxlib[=dir]
-cxxlib-icc	None
-F	-preprocess-only or -P
-fp	-fno-omit-frame-pointer
-fpstkchk	-fp-stack-check
-IPF-fp-speculation	-fp-speculation

Linux* OS and Mac OS* X Options	Suggested Replacement
-ipo-obj (and -ipo_obj)	None
-Kpic, -KPIC	-fpic
-mtune=itanium	None
-nobss-init	-no-bss-init
-opt-report-level	-opt-report
-prof-format-32	None
-prof-gen-sampling	None
-qp	-p
-shared-libcxa	-shared-libgcc
-ssp	None
-static-libcxa	-static-libgcc
-syntax	-syntax-only or -fsyntax-only
-tpp1	None
-tpp2	-mtune=itanium2
-tpp5	None
-tpp6	None
-tpp7	-mtune=pentium4
-xB	-xSSE2
-xi	None
-xM	None

Windows* OS Options	Suggested Replacement
/4ccD (and /4ccd)	None
/G1	None
/QaxB	/QaxSSE2
/Qaxi	None
/QaxM	None
/Qfpstkchk	/Qfp-stack-check
/QIPF-fp-speculation	/Qfp-speculation
/Qipo-obj (and /Qipo_obj)	None
/Qopt-report-level	/Qopt-report
/Qprof-format-32	None
/Qprof-gen-sampling	None
/Qssp	None
/Qvc6	None
/Qvc7	None
/QxB	/QxSSE2
/Qxi	None
/QxM	None

Removed options are not limited to these lists.

Alphabetical Compiler Options 20

Compiler Option Descriptions and General Rules

This section describes all the current Linux* OS, Mac OS* X, and Windows* OS compiler options in alphabetical order.

Option Descriptions

Each option description contains the following information:

- A short description of the option.
- IDE Equivalent
  This shows information related to the integrated development environment (IDE) Property Pages on Windows*, Linux*, and Mac OS* X systems. It shows on which Property Page the option appears, and under what category it's listed. The Windows IDE is Microsoft* Visual Studio* .NET; the Linux IDE is Eclipse*; the Mac OS X IDE is Xcode*. If the option has no IDE equivalent, it will specify "None". Note that in this release, there is no IDE support for Fortran on Linux.
- Architectures
  This shows the architectures where the option is valid. Possible architectures are:
  - IA-32 architecture
  - Intel® 64 architecture
  - IA-64 architecture
- Syntax
  This shows the syntax on Linux and Mac OS X systems and the syntax on Windows systems. If the option has no syntax on one of these systems, that is, the option is not valid on a particular system, it will specify "None".
- Arguments
  This shows any arguments (parameters) that are related to the option. If the option has no arguments, it will specify "None".
- Default
  This shows the default setting for the option.
- Description

This shows the full description of the option. It may also include further information on any applicable arguments.

- Alternate Options
  These are options that are synonyms of the described option. If there are no alternate options, it will specify "None".
  Many options have an older spelling where underscores ("_") instead of hyphens ("-") connect the main option names. The older spelling is a valid alternate option name.

Some option descriptions may also have the following:

- Example
  This shows a short example that includes the option
- See Also
  This shows where you can get further information on the option or related options.

General Rules for Compiler Options

You cannot combine options with a single dash (Linux OS and Mac OS X) or slash (Windows OS). For example:

- On Linux and Mac OS X systems: This is incorrect: `-wc`; this is correct: `-w -c`
- On Windows systems: This is incorrect: `/wc`; this is correct: `/w /c`

All Linux OS and Mac OS X compiler options are case sensitive. Many Windows OS options are case sensitive. Some options have different meanings depending on their case; for example, option "c" prevents linking, but option "C" checks for certain conditions at run time.

Options specified on the command line apply to all files named on the command line.

Options can take arguments in the form of file names, strings, letters, or numbers. If a string includes spaces, the string must be enclosed in quotation marks. For example:

- On Linux and Mac OS X systems, `-dynamic-linker` *`mylink`* (file name) or `-U`*`macro3`* (string)
- On Windows systems, `/Famyfile.s` (file name) or `/V"`*`version 5.0`*`"` (string)

Compiler options can appear in any order.

On Windows systems, all compiler options must precede `/link` options, if any, on the command line.

Unless you specify certain options, the command line will both compile and link the files you specify.

You can abbreviate some option names, entering as many characters as are needed to uniquely identify the option.

Certain options accept one or more keyword arguments following the option name. For example, the `arch` option accepts several keywords.

To specify multiple keywords, you typically specify the option multiple times. However, there are exceptions; for example, the following are valid: `-axNB` (Linux OS) or `/QaxNB` (Windows OS).

NOTE. On Windows systems, you can sometimes use a comma to separate keywords. For example, the following is valid:

```
ifort /warn:usage,declarations test.f90
```

On these systems, you can use an equals sign (=) instead of the colon:

```
ifort /warn=usage,declarations test.f90
```

Compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

To disable an option, specify the negative form of the option.

On Windows systems, you can also disable one or more options by specifying option `/Od` last on the command line.

NOTE. On Windows systems, the `/Od` option is part of a mutually-exclusive group of options that includes `/Od`, `/O1`, `/O2`, `/O3`, and `/Ox`. The last of any of these options specified on the command line will override the previous options from this group.

If there are enabling and disabling versions of an option on the command line, the last one on the command line takes precedence.

Lists and Functional Groupings of Compiler Options

To see a list of all the compiler options, specify option `help` on the command line.

To see functional groupings of compiler options, specify a functional category for option `help`. For example, to see a list of options that affect diagnostic messages displayed by the compiler, enter one of the following commands:

```
-help diagnostics     ! Linux and Mac OS X systems

/help diagnostics     ! Windows systems
```

For details on the categories you can specify, see help.

1

4Nf

See fixed.

4Nportlib, 4Yportlib

Determines whether the compiler links to the library of portability routines.

IDE Equivalent

Windows: **Libraries > Use Portlib Library**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/4Nportlib`

`/4Yportlib`

Arguments

None

Default

`/4Yportlib`	The library of portability routines is linked during compilation.

Description

Option `/4Yportlib` causes the compiler to link to the library of portability routines. This also includes Intel's functions for Microsoft* compatibility.

Option `/4Nportlib` prevents the compiler from linking to the library of portability routines.

Alternate Options

None

4Nportlib, 4Yportlib

Determines whether the compiler links to the library of portability routines.

IDE Equivalent

Windows: **Libraries > Use Portlib Library**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/4Nportlib`

`/4Yportlib`

Arguments

None

Default

`/4Yportlib`	The library of portability routines is linked during compilation.

Description

Option `/4Yportlib` causes the compiler to link to the library of portability routines. This also includes Intel's functions for Microsoft* compatibility.

Option `/4Nportlib` prevents the compiler from linking to the library of portability routines.

See extend-source.

align

Tells the compiler how to align certain data items.

IDE Equivalent

Windows: **Data > Structure Member Alignment** (`/align:rec`*n*`byte`)

Data > Common Element Alignment (`/align:[no]commons`, `/align:[no]dcommons`)

Data > SEQUENCE Types Obey Alignment Rules (`/align:[no]sequence`)

Linux: None

Mac OS X: **Data > Structure Member Alignment** (`-align rec<1,2,4,8,16>byte`)

Data > Common Element Alignment (`-align [no]commons`, `/align:[no]dcommons`)

Data > SEQUENCE Types Obey Alignment Rules (`-align [no]sequence`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-align [keyword]`

`-noalign`

Windows:

`/align[:keyword]`

`/noalign`

Arguments

keyword Specifies the data items to align. Possible values are:

`none`	Prevents padding bytes anywhere in common blocks and structures.
`[no]commons`	Affects alignment of common block entities.
`[no]dcommons`	Affects alignment of common block entities.
`[no]records`	Affects alignment of derived-type components and fields of record structures.
`rec`*n*`byte`	Specifies a size boundary for derived-type components and fields of record structures.
`[no]sequence`	Affects alignment of sequenced derived-type components.
`all`	Adds padding bytes whenever possible to data items in common blocks and structures.

Default

`nocommons`	Adds no padding bytes for alignment of common blocks.
`nodcommmons`	Adds no padding bytes for alignment of common blocks.
`records`	Aligns derived-type components and record structure fields on default natural boundaries.

`nosequence`	Causes derived-type components declared with the SEQUENCE statement to be packed, regardless of current alignment rules set by the user.

By default, no padding is added to common blocks but padding is added to structures.

Description

This option specifies the alignment to use for certain data items. The compiler adds padding bytes to perform the alignment.

Option	Description
`align none`	Tells the compiler not to add padding bytes anywhere in common blocks or structures. This is the same as specifying `noalign`.
`align commons`	Aligns all common block entities on natural boundaries up to 4 bytes, by adding padding bytes as needed. The `align nocommons` option adds no padding to common blocks. In this case, unaligned data can occur unless the order of data items specified in the COMMON statement places the largest numeric data item first, followed by the next largest numeric data (and so on), followed by any character data.
`align dcommons`	Aligns all common block entities on natural boundaries up to 8 bytes, by adding padding bytes as needed. This option is useful for applications that use common blocks, unless your application has no unaligned data or, if the application might have unaligned data, all data items are four bytes or smaller. For applications that use common blocks where all data items are four bytes or smaller, you can specify `/align:commons` instead of `/align:dcommons`. The `align nodcommons` option adds no padding to common blocks. On Windows systems, if you specify the `/stand:f90` or `/stand:f95` option, `/align:dcommons` is ignored. On Linux and Mac OS X systems, if you specify any `-std` option or the `-stand f90` or `-stand f95` option, `-align dcommons` is ignored.
`align norecords`	Aligns components of derived types and fields within record structures on arbitrary byte boundaries with no padding.

Option	Description
	The align records option requests that multiple data items in record structures and derived-type structures without the SEQUENCE statement be naturally aligned, by adding padding as needed.
`align rec`*`n`*`byte`	Aligns components of derived types and fields within record structures on the smaller of the size boundary specified (*`n`*) or the boundary that will naturally align them. *`n`* can be 1, 2, 4, 8, or 16. When you specify this option, each structure member after the first is stored on either the size of the member type or *`n`*-byte boundaries, whichever is smaller. For example, to specify 2 bytes as the packing boundary (or alignment constraint) for all structures and unions in the file prog1.f, use the following command: `ifort {-align rec2byte | /align:rec2byte} prog1.f` This option does not affect whether common blocks are naturally aligned or packed.
`align sequence`	Aligns components of a derived type declared with the SEQUENCE statement (sequenced components) according to the alignment rules that are currently in use. The default alignment rules are to align unsequenced components on natural boundaries. The `align nosequence` option requests that sequenced components be packed regardless of any other alignment rules. Note that `align none` implies `align nosequence`. If you specify an option for standards checking, `/align:sequence` is ignored.
`align all`	Tells the compiler to add padding bytes whenever possible to obtain the natural alignment of data items in common blocks, derived types, and record structures. Specifies `align nocommons, align dcommons, align records, align nosequence`. This is the same as specifying `align` with no *`keyword`*.

Alternate Options

`align none`	Linux and Mac OS X: `-noalign` Windows: `/noalign`

`align records`	Linux and Mac OS X: `-align rec16byte`, `-Zp16` Windows: `/align:rec16byte`, `/Zp16`
`align norecords`	Linux and Mac OS X: `-Zp1`, `-align rec1byte` Windows: `/Zp1`, `/align:rec1byte`
`align rec`*n*`byte`	Linux and Mac OS X: `-Zp{1|2|4|8|16}` Windows: `/Zp{1|2|4|8|16}`
`align all`	Linux and Mac OS X: `-align commons -align dcommons -align records -align nosequence` Windows: `/align:nocommons,dcommons,records,nosequence`

See Also

- Optimizing Applications: Setting Data Type and Alignment

allow

Determines whether the compiler allows certain behaviors.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-allow` *keyword*

Windows:

`/allow:`*keyword*

Arguments

keyword	Specifies the behaviors to allow or disallow. Possible values are:

`[no]fpp_comments`	Determines how the fpp preprocessor treats Fortran end-of-line comments in preprocessor directive lines.

Default

`fpp_comments`	The compiler recognizes Fortran-style end-of-line comments in preprocessor lines.

Description

This option determines whether the compiler allows certain behaviors.

Option	Description
`allow nofpp_comments`	Tells the compiler to disallow Fortran-style end-of-line comments on preprocessor lines. Comment indicators have no special meaning.

Alternate Options

None

Example

Consider the following:

```
#define MAX_ELEMENTS 100  ! Maximum number of elements
```

By default, the compiler recognizes Fortran-style end-of-line comments on preprocessor lines. Therefore, the line above defines MAX_ELEMENTS to be "100" and the rest of the line is ignored. If `allow nofpp_comments` is specified, Fortran comment conventions are not used and the comment indicator "!" has no special meaning. So, in the above example, "! Maximum number of elements" is interpreted as part of the value for the MAX_ELEMENTS definition.

Option `allow nofpp_comments` can be useful when you want to have a Fortran directive as a define value; for example:

```
#define dline(routname) !dec$ attributes alias:"__routname":: routname
```

altparam

Allows alternate syntax (without parentheses) for PARAMETER statements.

IDE Equivalent

Windows: **Language > Enable Alternate PARAMETER Syntax**

Linux: None

Mac OS X: **Language > Enable Alternate PARAMETER Syntax**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-altparam
-noaltparam
```

Windows:

```
/altparam
/noaltparam
```

Arguments

None

Default

`altparam`	The alternate syntax for PARAMETER statements is allowed.

Description

This option specifies that the alternate syntax for PARAMETER statements is allowed. The alternate syntax is:

```
PARAMETER c = expr [, c = expr] ...
```

This statement assigns a name to a constant (as does the standard PARAMETER statement), but there are no parentheses surrounding the assignment list.

In this alternative statement, the form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

Alternate Options

`altparam`	Linux and Mac OS X: `-dps` Windows: `/Qdps`, `/4Yaltparam`
`noaltparam`	Linux and Mac OS X: `-nodps` Windows: `/Qdps-`, `/4Naltparam`

ansi-alias, Qansi-alias

Tells the compiler to assume that the program adheres to Fortran Standard type aliasability rules.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ansi-alias`

`-no-ansi-alias`

Windows:

`Qansi-alias`

`Qansi-alias-`

Arguments

None

Default

`-ansi-alias` or `/Qansi-alias`	Programs adhere to Fortran Standard type aliasability rules.

Description

This option tells the compiler to assume that the program adheres to type aliasability rules defined in the Fortran Standard.

For example, an object of type real cannot be accessed as an integer. For information on the rules for data types and data type constants, see "Data Types, Constants, and Variables" in the Language Reference.

This option directs the compiler to assume the following:

- Arrays are not accessed out of arrays' bounds.
- Pointers are not cast to non-pointer types and vice-versa.
- References to objects of two different scalar types cannot alias. For example, an object of type integer cannot alias with an object of type real or an object of type real cannot alias with an object of type double precision.

If your program adheres to the Fortran Standard type aliasability rules, this option enables the compiler to optimize more aggressively. If it doesn't adhere to these rules, then you should disable the option with `-no-ansi-alias` (Linux and Mac OS X) or `/Qansi-alias-` (Windows) so the compiler does not generate incorrect code.

Alternate Options

None

arch

Tells the compiler to generate optimized code specialized for the processor that executes your program.

IDE Equivalent

Windows: **Code Generation > Enable Enhanced Instruction Set**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-arch`*`processor`*

Windows:

`/arch:`*`processor`*

Arguments

`processor` Is the processor type. Possible values are:

`IA32`	Generates code that will run on any Pentium or later processor. Disables any default extended instruction settings, and any previously set extended instruction settings. This value is only available on Linux and Windows systems using IA-32 architecture.
`SSE`	This is the same as specifying `IA32`.
`SSE2`	Generates code for Intel® Streaming SIMD Extensions 2 (Intel® SSE2). This value is only available on Linux and Windows systems.
`SSE3`	Generates code for Intel® Streaming SIMD Extensions 3 (Intel® SSE3).
`SSSE3`	Generates code for Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3).
`SSE4.1`	Generates code for Intel® Streaming SIMD Extensions 4 Vectorizing Compiler and Media Accelerators.

Default

Windows and Linux systems: For more information on the default values, see Arguments above.
`SSE2`
Mac OS X systems using
IA-32 architecture: `SSE3`

Mac OS X systems using
Intel® 64 architecture:
SSSE3

Description

This option tells the compiler to generate optimized code specialized for the processor that executes your program.

Code generated with the values IA32, SSE, SSE2, or SSE3 should execute on any compatible non-Intel processor with support for the corresponding instruction set.

Options /arch and /Qx are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

For compatibility with Compaq* Visual Fortran, the compiler allows the following keyword values. However, you should use the suggested replacements.

Compatibility Value	Suggested Replacement
pn1	-mia32 or /arch:IA32
pn2	-mia32 or /arch:IA32
pn3	-mia32 or /arch:IA32
pn4	-msse2 or /arch:SSE2

Alternate Options

Linux and Mac OS X: -m

Windows: /architecture

See Also

-
- x, Qx
- ax, Qax
- m

architecture

See arch.

asmattr

Specifies the contents of an assembly listing file.

IDE Equivalent

Windows: **Output > Assembler Output**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/asmattr:`*`keyword`*

`/noasmattr`

Arguments

keyword	Specifies the contents of the assembly listing file. Possible values are:	
	`none`	Produces no assembly listing.
	`machine`	Produces an assembly listing with machine code.
	`source`	Produces an assembly listing with source code.
	`all`	Produces an assembly listing with machine code and source code.

Default

/noasmattr	No assembly listing is produced.

Description

This option specifies what information, in addition to the assembly code, should be generated in the assembly listing file.

To use this option, you must also specify option /asmfile, which causes an assembly listing to be generated.

Option	Description
/asmattr:none	Produces no assembly listing. This is the same as specifying /noasmattr.
/asmattr:machine	Produces an assembly listing with machine code. The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the filename is the name of the source file with an extension of .cod.
/asmattr:source	Produces an assembly listing with source code. The assembly listing file shows the source code as interspersed comments. Note that if you use alternate option -fsource-asm, you must also specify the -S option.
/asmattr:all	Produces an assembly listing with machine code and source code. The assembly listing file shows the source code as interspersed comments and shows the hex machine instructions at the beginning of each line of assembly code. This file cannot be assembled.

Alternate Options

/asmattr:none	Linux and Mac OS X: None Windows: /noasmattr
/asmattr:machine	Linux and Mac OS X: -fcode-asm Windows: /FAc
/asmattr:source	Linux and Mac OS X: -fsource-asm Windows: /FAs

`/asmattr:all`	Linux and Mac OS X: None Windows: `/FAcs`

See Also

-
- `asmfile`

asmfile

Specifies that an assembly listing file should be generated.

IDE Equivalent

Windows: **Output > ASM Listing Name**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/asmfile[:`*`file`* `|` *`dir`*`]`

`/noasmfile`

Arguments

`file`	Is the name of the assembly listing file.
`dir`	Is the directory where the file should be placed. It can include *`file`*.

Default

`/noasmfile`	No assembly listing file is produced.

Description

This option specifies that an assembly listing file should be generated (optionally named *file*).

If *file* is not specified, the filename will be the name of the source file with an extension of .asm; the file is placed in the current directory.

Alternate Options

Linux and Mac OS X: -S

Windows: /Fa

- S

assume

Tells the compiler to make certain assumptions.

IDE Equivalent

Windows: **Compatibility > Treat Backslash as Normal Character in Strings** (/assume:[no]bscc)

Data > Assume Dummy Arguments Share Memory Locations (/assume:[no]dummy_aliases)

Data > Constant Actual Arguments Can Be Changed (/assume:[no]protect_constants)

Data > Use Bytes as RECL=Unit for Unformatted Files (/assume:[no]byterecl)

Floating Point > Enable IEEE Minus Zero Support (/assume:[no]minus0)

Optimization > I/O Buffering (/assume:[no]buffered_io)

Preprocessor > Default Include and Use Path (/assume:[no]source_include)

Preprocessor > OpenMP Conditional Compilation (/assume:[no]cc_omp)

External Procedures > Append Underscore to External Names (/assume:[no]underscore)

Linux: None

Mac OS X: **Optimization > I/O Buffering** (-assume [no]buffered_io)

Preprocessor > OpenMP Conditional Compilation (`-assume [no]cc_omp`)

Preprocessor > Default Include and Use Path (`-assume [no]source_include`)

Compatibility > Treat Backslash as Normal Character in Strings (`-assume [no]bscc`)

Data > Assume Dummy Arguments Share Memory Locations (`-assume [no]dummy_aliases`)

Data > Constant Actual Arguments Can Be Changed (`-assume [no]protect_constants`)

Data > Use Bytes as RECL=Unit for Unformatted Files (`-assume [no]byterecl`)

Floating Point > Enable IEEE Minus Zero Support (`-assume [no]minus0`)

External Procedures > Append Underscore to External Names (`-assume [no]underscore`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-assume` *keyword*

Windows:

`/assume:`*keyword*

Arguments

keyword Specifies the assumptions to be made. Possible values are:

`none`	Disables all assume options.
`[no]bscc`	Determines whether the backslash character is treated as a C-style control character syntax in character literals.
`[no]buffered_io`	Determines whether data is immediately written to disk or accumulated in a buffer.
`[no]byterecl`	Determines whether units for the OPEN statement RECL specifier (record length) value in unformatted files are in bytes or longwords (four-byte units).

[no]cc_omp	Determines whether conditional compilation as defined by the OpenMP Fortran API is enabled or disabled.
[no]dummy_aliases	Determines whether the compiler assumes that dummy arguments to procedures share memory locations with other dummy arguments or with COMMON variables that are assigned.
[no]ieee_fpe_flags	Determines whether the floating-point exception and status flags are saved on routine entry and restored on routine exit.
[no]minus0	Determines whether the compiler uses Fortran 95 or Fortran 90/77 standard semantics in the SIGN intrinsic when treating -0.0 and +0.0 as 0.0, and how it writes the value on formatted output.
[no]old_boz	Determines whether the binary, octal, and hexadecimal constant arguments in intrinsic functions INT, REAL, DBLE, and CMPLX are treated as signed integer constants.
[no]old_logical_ldio	Determines whether NAMELIST and list-directed input accept logical values for numeric IO-list items.
[no]old_maxminloc	Determines the results of intrinsics MAXLOC and MINLOC when given an empty array as an argument.
[no]old_unit_star	Determines whether READs or WRITEs to UNIT=* go to stdin or stdout, respectively.
[no]old_xor	Determines whether .XOR. is defined by the compiler as an intrinsic operator.
[no]protect_constants	Determines whether a constant actual argument or a copy of it is passed to a called routine.

[no]protect_parens	Determines whether the optimizer honors parentheses in REAL and COMPLEX expression evaluations by not reassociating operations.
[no]realloc_lhs	Determines whether allocatable objects on the left-hand side of an assignment are treated according to Fortran 95/90 rules or Fortran 2003 rules.
[no]source_include	Determines whether the compiler searches for USE modules and INCLUDE files in the default directory or in the directory where the source file is located.
[no]std_mod_proc_name	Determines whether the names of module procedures are allowed to conflict with user external symbol names.
[no]underscore	Determines whether the compiler appends an underscore character to external user-defined names.
[no]2underscores (Linux and Mac OS X)	Determines whether the compiler appends two underscore characters to external user-defined names.
[no]writeable_strings	Determines whether character constants go into non-read-only memory.

Default

nobscc	The backslash character is treated as a normal character in character literals.
nobuffered_io	Data in the internal buffer is immediately written (flushed) to disk (OPEN specifier BUFFERED='NO'). If you set the FORT_BUFFERED environment variable to true, the default is `assume buffered_io`.
nobyterecl	Units for OPEN statement RECL values with unformatted files are in four-byte (longword) units.

nocc_omp	Conditional compilation as defined by the OpenMP Fortran API is disabled unless option -openmp (Linux) or /Qopenmp (Windows) is specified. If compiler option -openmp (Linux and Mac OS X) or /Qopenmp (Windows) is specified, the default is assume cc_omp.
nodummy_aliases	Dummy arguments to procedures do not share memory locations with other dummy arguments or with variables shared through use association, host association, or common block use.
noieee_fpe_flags	The flags are not saved on routine entry and they are not restored on routine exit.
nominus0	The compiler uses Fortran 90/77 standard semantics in the SIGN intrinsic to treat -0.0 and +0.0 as 0.0, and writes a value of 0.0 with no sign on formatted output.
noold_boz	The binary, octal, and hexadecimal constant arguments in intrinsic functions INT, REAL, DBLE, and CMPLX are treated as bit strings that represent a value of the data type of the intrinsic, that is, the bits are not converted.
noold_logical_ldio	Tells the compiler that NAMELIST and list-directed input cannot accept logical values (T, F, etc.) for numeric (integer, real, and complex) IO-list items. If this option is specified and a logical value is given for a numeric item in NAMELIST and list-directed input, a runtime error will be produced.
old_maxminloc	MAXLOC and MINLOC return 1 when given an empty array as an argument.
noold_unit_star	The READs or WRITEs to UNIT=* go to stdin or stdout, respectively, even if UNIT=5 or 6 has been connected to another file.
old_xor	Intrinsic operator .XOR. is defined by the compiler.
protect_constants	A constant actual argument is passed to a called routine. Any attempt to modify it results in an error.
noprotect_parens	The optimizer reorders REAL and COMPLEX expressions without regard for parentheses if it produces faster executing code.
norealloc_lhs	The compiler uses Fortran 95/90 rules when interpreting assignment statements. The left-hand side is assumed to be allocated with the correct shape to hold the right-hand side. If it is not, incorrect behavior will occur.
source_include	The compiler searches for USE modules and INCLUDE files in the directory where the source file is located.

`nostd_mod_proc_name`	The compiler allows the names of module procedures to conflict with user external symbol names.
Windows: `nounderscore` Linux and Mac OS X: `under-score`	On Windows systems, the compiler does not append an underscore character to external user-defined names. On Linux and Mac OS X systems, the compiler appends an underscore character to external user-defined names.
`no2underscores` (Linux and Mac OS X)	The compiler does not append two underscore characters to external user-defined names that contain an embedded underscore.
`nowriteable-strings`	The compiler puts character constants into read-only memory.

Description

This option specifies assumptions to be made by the compiler.

Option	Description
`assume none`	Disables all the assume options.
`assume bscc`	Tells the compiler to treat the backslash character (\) as a C-style control (escape) character syntax in character literals. The "bscc" keyword means "BackSlashControlCharacters."
`assume buffered_io`	Tells the compiler to accumulate records in a buffer. This sets the default for opening sequential output files to BUFFERED='YES', which also occurs if the FORT_BUFFERED run-time environment variable is specified. When this option is specified, the internal buffer is filled, possibly by many record output statements (WRITE), before it is written to disk by the Fortran run-time system. If a file is opened for direct access, I/O buffering is ignored. Using buffered writes usually makes disk I/O more efficient by writing larger blocks of data to the disk less often. However, if you request buffered writes, records not yet written to disk may be lost in the event of a system failure. The OPEN statement BUFFERED specifier applies to a specific logical unit. In contrast, the `assume [no]buffered_io` option and the FORT_BUFFERED environment variable apply to all Fortran units.

Option	Description
`assume byterecl`	Specifies that the units for the OPEN statement RECL specifier (record length) value are in bytes for unformatted data files, not longwords (four-byte units). For formatted files, the RECL value is always in bytes. If a file is open for unformatted data and `assume byterecl` is specified, INQUIRE returns RECL in bytes; otherwise, it returns RECL in longwords. An INQUIRE returns RECL in bytes if the unit is not open.
`assume cc_omp`	Enables conditional compilation as defined by the OpenMP Fortran API. That is, when "!$space" appears in free-form source or "c$spaces" appears in column 1 of fixed-form source, the rest of the line is accepted as a Fortran line.
`assume dummy_aliases`	Tells the compiler that dummy (formal) arguments to procedures share memory locations with other dummy arguments (aliases) or with variables shared through use association, host association, or common block use. Specify the option when you compile the called subprogram. The program semantics involved with dummy aliasing do not strictly obey the Fortran 95/90 standards and they slow performance, so you get better run-time performance if you do not use this option. However, if a program depends on dummy aliasing and you do not specify this option, the run-time behavior of the program will be unpredictable. In such programs, the results will depend on the exact optimizations that are performed. In some cases, normal results will occur, but in other cases, results will differ because the values used in computations involving the offending aliases will differ.
`assume ieee_fpe_flags`	Tells the compiler to save floating-point exception and status flags on routine entry and restore them on routine exit. This option can slow runtime performance because it provides extra code to save and restore the floating-point exception and status flags (and the rounding mode) on entry to and exit from every routine compiled with the option. This option can be used to get the full Fortran Standard behavior of intrinsic modules IEEE EXCEPTIONS, IEEE ARITHMETIC, and IEEE FEATURES, which require that if a flag is signaling on routine entry, the

Option	Description
	processor will set it to quiet on entry and restore it to signaling on return. If a flag signals while the routine is executing, it will not be set to quiet on routine exit. Options `fpe` and `fpe-all` can be used to set the initial state for which floating-point exceptions will signal.
`assume minus0`	Tells the compiler to use Fortran 95 standard semantics for the treatment of the IEEE* floating value -0.0 in the SIGN intrinsic, which distinguishes the difference between -0.0 and +0.0, and to write a value of -0.0 with a negative sign on formatted output.
`assume old_boz`	Tells the compiler that the binary, octal, and hexadecimal constant arguments in intrinsic functions INT, REAL, DBLE, and CMPLX should be treated as signed integer constants.
`assume old_logical_ldio`	Logical values are allowed for numeric items.
`assume noold_maxminloc`	Tells the compiler that MAXLOC and MINLOC should return 0 when given an empty array as an argument. Compared to the default setting (`old_maxminloc`), this behavior may slow performance because of the extra code needed to check for an empty array argument.
`assume old_unit_star`	Tells the compiler that READs or WRITEs to UNIT=* go to whatever file UNIT=5 or 6 is connected.
`assume noold_xor`	Prevents the compiler from defining .XOR. as an intrinsic operator. This lets you use .XOR. as a user-defined operator. This is a Fortran 2003 feature.
`assume noprotect_constants`	Tells the compiler to pass a copy of a constant actual argument. This copy can be modified by the called routine, even though the Fortran standard prohibits such modification. The calling routine does not see any modification to the constant.

Option	Description
`assume protect_parens`	Tells the optimizer to honor parentheses in REAL and COMPLEX expression evaluations by not reassociating operations. For example, (A+B)+C would not be evaluated as A+(B+C). If assume noprotect_parens is specified, (A+B)+C would be treated the same as A+B+C and could be evaluated as A+(B+C) if it produced faster executing code. Such reassociation could produce different results depending on the sizes and precision of the arguments. For example, in (A+B)+C, if B and C had opposite signs and were very large in magnitude compared to A, A+B could result in the value as B; adding C would result in 0.0. With reassociation, B+C would be 0.0; adding A would result in a non-zero value.
`assume realloc_lhs`	Tells the compiler that when the left-hand side of an assignment is an allocatable object, it should be reallocated to the shape of the right-hand side of the assignment before the assignment occurs. This is the Fortran 2003 definition. This feature may cause extra overhead at run time.
`assume nosource_include`	Tells the compiler to search the default directory for module files specified by a USE statement or source files specified by an INCLUDE statement. This option affects fpp preprocessor behavior and the USE statement.
`assume std_mod_proc_name`	Tells the compiler to revise the names of module procedures so they do not conflict with user external symbol names. For example, procedure `proc` in module *`m`* would be named `m_MP_proc`. The Fortran 2003 Standard requires that module procedure names not conflict with other external symbols. By default, procedure `proc` in module m would be named `m_mp_proc`, which could conflict with a user-defined external name `m_mp_proc`.
`assume underscore`	Tells the compiler to append an underscore character to external user-defined names: the main program name, named common blocks, BLOCK DATA blocks, global data names in MODULEs, and names implicitly or explicitly declared EXTERNAL. The name of a blank (unnamed) common block remains _BLNK__, and Fortran intrinsic names are not affected.

Option	Description
`assume 2underscores` (Linux and Mac OS X)	Tells the compiler to append two underscore characters to external user-defined names that contain an embedded underscore: the main program name, named common blocks, BLOCK DATA blocks, global data names in MODULEs, and names implicitly or explicitly declared EXTERNAL. The name of a blank (unnamed) common block remains _BLNK__, and Fortran intrinsic names are not affected. This option does not affect external names that do not contain an embedded underscore. By default, the compiler only appends one underscore to those names. For example, if you specify `assume 2underscores` for external names *my_program* and *myprogram*, *my_program* becomes *my_program__*, but *myprogram* becomes *myprogram_*.
`assume writeable-strings`	Tells the compiler to put character constants into non-read-only memory.

Alternate Options

`assume nobscc`	Linux and Mac OS X: `-nbs` Windows: `/nbs`
`assume dummy_aliases`	Linux and Mac OS X: `-common-args` Windows: `/Qcommon-args`
`assume underscore`	Linux and Mac OS X: `-us` Windows: `/us`
`assume nounderscore`	Linux and Mac OS X: `-nus` Windows: None

- `fpe-all`

auto, Qauto

See automatic.

auto-scalar, Qauto-scalar

Causes scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute to be allocated to the run-time stack.

IDE Equivalent

Windows: **Data > Local Variable Storage** (`/Qsave`, `/Qauto`, `/Qauto_scalar`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-auto-scalar`

Windows:

`/Qauto-scalar`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`	Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute are allocated to the run-time stack. Note that if option `recursive`, `-openmp` (Linux and Mac OS X), or `/Qopenmp` (Windows) is specified, the default is `automatic`.

Description

This option causes allocation of scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL to the run-time stack. It is as if they were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute (which include initialized locals) or that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across subroutine calls should appear in a SAVE statement.

You cannot specify option `save`, `auto`, or `automatic` with this option.

NOTE. On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `/automatic`, `/auto`, or `/Qauto` because arrays are allocated on the stack along with scalars. However, with `/Qauto-scalar`, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. `/Qauto-scalar` enables the compiler to make better choices about which variables should be kept in registers during program execution.

Alternate Options

None

See Also

-
-
- `auto`
- `save`

autodouble, Qautodouble

See real-size.

automatic

Causes all local, non-SAVEd variables to be allocated to the run-time stack.

IDE Equivalent

Windows: **Data > Local Variable Storage**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-automatic`

`-noautomatic`

Windows:

`/automatic`

`/noautomatic`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`	Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that if one of the following options are specified, the default is `automatic:recursive`, `-openmp` (Linux and Mac OS X), or `/Qopenmp` (Windows).

Description

This option places local variables (scalars and arrays of all types), except those declared as SAVE, on the run-time stack. It is as if the variables were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute or ALLOCATABLE attribute, or variables that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly.

If you want to cause variables to be placed in static memory, specify option `-save` (Linux and Mac OS X) or `/Qsave` (Windows). If you want only scalar variables of certain intrinsic types to be placed on the run-time stack, specify option `auto-scalar`.

NOTE. On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `/automatic`, `/auto`, or `/Qauto` because arrays are allocated on the stack along with scalars. However, with `/Qauto-scalar`, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. `/Qauto-scalar` enables the compiler to make better choices about which variables should be kept in registers during program execution.

Alternate Options

`automatic`	Linux and Mac OS X: `-auto` Windows: `/auto`, `/Qauto`, `/4Ya`
`noautomatic`	Linux and Mac OS X: `-save`, `-noauto` Windows: `/Qsave`, `/noauto`, `/4Na`

See Also

ax, Qax

Tells the compiler to generate multiple, processor-specific auto-dispatch code paths for Intel processors if there is a performance benefit.

IDE Equivalent

Windows: **Code Generation > Add Processor-Optimized Code Path**

Optimization > Generate Alternate Code Paths

Linux: None

Mac OS X: **Code Generation > Add Processor-Optimized Code Path**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-ax`*`processor`*

Windows:

`/Qax`*`processor`*

Arguments

`processor`

Indicates the processor for which code is generated. The following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (Intel® SSSE). Possible values are:

`SSE4.2`

Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.

`SSE4.1`	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture. This replaces value S, which is deprecated.
`SSSE3`	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. For Mac OS* X systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.
`SSE3`	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. For Mac OS* X systems, this value is only supported on IA-32 architecture. This replaces value P, which is deprecated.
`SSE2`	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2. This value is not available on Mac OS* X systems. This replaces value N, which is deprecated.

Default

OFF	No auto-dispatch code is generated. Processor-specific code is generated and is controlled by the setting of compiler option `-m` (Linux), compiler option `/arch` (Windows), or compiler option `-x` (Mac OS* X).

Description

This option tells the compiler to generate multiple, processor-specific auto-dispatch code paths for Intel processors if there is a performance benefit. It also generates a baseline code path. The baseline code is usually slower than the specialized code.

The baseline code path is determined by the architecture specified by the `-x` (Linux and Mac OS X) or `/Qx` (Windows) option. While there are defaults for the `-x` or `/Qx` option that depend on the operating system being used, you can specify an architecture for the baseline code that is higher or lower than the default. The specified architecture becomes the effective minimum architecture for the baseline code path.

If you specify both the `-ax` and `-x` options (Linux and Mac OS X) or the `/Qax` and `/Qx` options (Windows), the baseline code will only execute on processors compatible with the processor type specified by the `-x` or `/Qx` option.

This option tells the compiler to find opportunities to generate separate versions of functions that take advantage of features of the specified Intel® processor.

If the compiler finds such an opportunity, it first checks whether generating a processor-specific version of a function is likely to result in a performance gain. If this is the case, the compiler generates both a processor-specific version of a function and a baseline version of the function. At run time, one of the versions is chosen to execute, depending on the Intel processor in use. In this way, the program can benefit from performance gains on more advanced Intel processors, while still working properly on older processors.

You can use more than one of the processor values by combining them. For example, you can specify `-axSSE4.1,SSSE3` (Linux and Mac OS X) or `/QaxSSE4.1,SSSE3` (Windows). You cannot combine the old style, deprecated options and the new options. For example, you cannot specify `-axSSE4.1,T` (Linux and Mac OS X) or `/QaxSSE4.1,T` (Windows).

Previous values W and K are deprecated. The details on replacements are as follows:

- Mac OS X systems: On these systems, there is no exact replacement for W or K. You can upgrade to the default option `-msse3` (IA-32 architecture) or option `-mssse3` (Intel® 64 architecture).
- Windows and Linux systems: The replacement for W is `-msse2` (Linux) or `/arch:SSE2` (Windows). There is no exact replacement for K. However, on Windows systems, `/QaxK` is interpreted as `/arch:IA32`; on Linux systems, `-axK` is interpreted as `-mia32`. You can also do one of the following:
  - Upgrade to option `-msse2` (Linux) or option `/arch:SSE2` (Windows). This will produce one code path that is specialized for Intel® SSE2. It will not run on earlier processors

- Specify the two option combination `-mia32 -axSSE2` (Linux) or `/arch:IA32 /QaxSSE2` (Windows). This combination will produce an executable that runs on any processor with IA-32 architecture but with an additional specialized Intel® SSE2 code path.

The `-ax` and `/Qax` options enable additional optimizations not enabled with option `-m` or option `/arch`.

Alternate Options

None

See Also

-
-
- `x`, `Qx`
- `m`
- `arch`

B

Specifies a directory that can be used to find include files, libraries, and executables.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-B`*`dir`*

Windows:

`None`

Arguments

dir	Is the directory to be used. If necessary, the compiler adds a directory separator character at the end of *dir*.

Default

OFF	The compiler looks for files in the directories specified in your PATH environment variable.

Description

This option specifies a directory that can be used to find include files, libraries, and executables.

The compiler uses *dir* as a prefix.

For include files, the *dir* is converted to `-I`*dir*/include. This command is added to the front of the includes passed to the preprocessor.

For libraries, the *dir* is converted to `-L`*dir*. This command is added to the front of the standard `-L` inclusions before system libraries are added.

For executables, if *dir* contains the name of a tool, such as `ld` or `as`, the compiler will use it instead of those found in the default directories.

The compiler looks for include files in *dir* /include while library files are looked for in *dir*.

Another way to get the behavior of this option is to use the environment variable `GCC_EXEC_PREFIX`.

Alternate Options

None

Bdynamic

Enables dynamic linking of libraries at run time.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-Bdynamic`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

OFF	Limited dynamic linking occurs.

Description

This option enables dynamic linking of libraries at run time. Smaller executables are created than with static linking.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option `-Bdynamic` are linked dynamically until the end of the command line or until a `-Bstatic` option is encountered. The `-Bstatic` option enables static linking of libraries.

Alternate Options

None

See Also

-
- `Bstatic`

bigobj

Increases the number of sections that an object file can contain.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
None
```

Windows:

```
/bigobj
```

Arguments

None

Default

OFF	An object file can hold up to 65,536 (2**16) addressable sections.

Description

This option increases the number of sections that an object file can contain. It increases the address capacity to 4,294,967,296(2**32).

An .obj file produced with this option can only be effectively passed to a linker that shipped in Microsoft Visual C++* 2005 or later. Linkers shipped with earlier versions of the product cannot read .obj files of this size.

This option may be helpful for .obj files that can hold more sections, such as machine generated code.

Alternate Options

None

bintext

Places a text string into the object file (.obj) being generated by the compiler.

IDE Equivalent

Windows: **Code Generation > Object Text String**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/bintext:`*`string`*

`/nobintext`

Arguments

`string`	Is the text string to go into the object file.

Default

`/nobintext`	No text string is placed in the object file.

Description

This option places a text string into the object file (.obj) being generated by the compiler. The string also gets propagated into the executable file.

For example, this option is useful if you want to place a version number or copyright information into the object and executable.

If the string contains a space or tab, the string must be enclosed by double quotation marks ("). A backslash (\) must precede any double quotation marks contained within the string.

If the command line contains multiple `/bintext` options, the last (rightmost) one is used.

Alternate Options

Linux and Mac OS X: None

Windows: `/Vstring`

Bstatic

Enables static linking of a user's library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-Bstatic`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

OFF	Default static linking occurs.

Description

This option enables static linking of a user's library.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option `-Bstatic` are linked statically until the end of the command line or until a `-Bdynamic` option is encountered. The `-Bdynamic` option enables dynamic linking of libraries.

Alternate Options

None

See Also

-
- `Bdynamic`

c

Prevents linking.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-c`

Windows:

`/c`

Arguments

None

Default

OFF	Linking is performed.

Description

This option prevents linking. Compilation stops after the object file is generated.

The compiler generates an object file for each Fortran source file.

Alternate Options

Linux and Mac OS X: None

Windows: `/compile-only`, `/nolink`

C

See check.

CB

See check.

ccdefault

Specifies the type of carriage control used when a file is displayed at a terminal screen.

IDE Equivalent

Windows: **Run-time > Default Output Carriage Control**

Linux: None

Mac OS X: **Run-time > Default Output Carriage Control**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ccdefault` *`keyword`*

Windows:

`/ccdefault:`*`keyword`*

Arguments

keyword — Specifies the carriage-control setting to use. Possible values are:

`none`	Tells the compiler to use no carriage control processing.
`default`	Tells the compiler to use the default carriage-control setting.
`fortran`	Tells the compiler to use normal Fortran interpretation of the first character. For example, the character 0 causes output of a blank line before a record.
`list`	Tells the compiler to output one line feed between records.

Default

`ccdefault default` — The compiler uses the default carriage control setting.

Description

This option specifies the type of carriage control used when a file is displayed at a terminal screen (units 6 and *). It provides the same functionality as using the CARRIAGECONTROL specifier in an OPEN statement.

The default carriage-control setting can be affected by the `vms` option. If `vms` is specified with `ccdefault default`, carriage control defaults to normal Fortran interpretation (`ccdefault fortran`) if the file is formatted and the unit is connected to a terminal. If `novms` (the default) is specified with `ccdefault default`, carriage control defaults to list (`ccdefault list`).

Alternate Options

None

check

Checks for certain conditions at run time.

IDE Equivalent

Windows:

Run-time > Runtime Error Checking (`/nocheck`, `/check:all`, or `/xcheck:none`)

Run-time > Check Array and String Bounds (`/check:[no]bounds`)

Run-time > Check Uninitialized Variables (`/check:[no]uninit`)

Run-time > Check Edit Descriptor Data Type (`/check:[no]format`)

Run-time > Check Edit Descriptor Data Size (`/check:[no]output_conversion`)

Run-time > Check For Actual Arguments Using Temporary Storage (`/check:[no]arg_temp_created`)

Run-time > **Check For Null Pointers and Allocatable Array References** (`/check:[no]pointers`)

Linux: None

Mac OS X: Run-time > Runtime Error Checking (`-check all, -check none`)

Run-time > Check Array and String Bounds (`-check [no]bounds`)

Run-time > Check Edit Descriptor Data Type (`-check [no]format`)

Run-time > Check Edit Descriptor Data Size (`-check [no]output_conversion`)

Run-time > Check For Actual Arguments Using Temporary Storage (`-check [no]arg_temp_created`)

Run-time > Check for Uninitialized Variables (`-check [no]uninit`)

Run-time > Check For Null Pointers and Allocatable Array References (`/check:[no]pointers`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-check [keyword]`

`-nocheck`

Windows:

`/check[:keyword]`

`/nocheck`

Arguments

keyword Specifies the conditions to check. Possible values are:

`none`	Disables all check options.
`[no]arg_temp_created`	Determines whether checking occurs for actual arguments before routine calls.
`[no]bounds`	Determines whether checking occurs for array subscript and character substring expressions.
`[no]format`	Determines whether checking occurs for the data type of an item being formatted for output.
`[no]output_conversion`	Determines whether checking occurs for the fit of data items within a designated format descriptor field.
`[no]pointers`	Determines whether checking occurs for certain disassociated or uninitialized pointers or unallocated allocatable objects.
`[no]uninit`	Determines whether checking occurs for uninitialized variables.
`all`	Enables all check options.

Default

`nocheck` No checking is performed for run-time failures. Note that if option `vms` is specified, the defaults are `check format` and `check output_conversion`.

Description

This option checks for certain conditions at run time.

Option	Description
`check none`	Disables all check options (same as `nocheck`).

Option	Description
`check arg_temp_created`	Enables run-time checking on whether actual arguments are copied into temporary storage before routine calls. If a copy is made at run-time, an informative message is displayed.
`check bounds`	Enables compile-time and run-time checking for array subscript and character substring expressions. An error is reported if the expression is outside the dimension of the array or the length of the string. For array bounds, each individual dimension is checked. Array bounds checking is not performed for arrays that are dummy arguments in which the last dimension bound is specified as * or when both upper and lower dimensions are 1. Once the program is debugged, omit this option to reduce executable program size and slightly improve run-time performance.
`check format`	Issues the run-time FORVARMIS fatal error when the data type of an item being formatted for output does not match the format descriptor being used (for example, a REAL*4 item formatted with an I edit descriptor). With check noformat, the data item is formatted using the specified descriptor unless the length of the item cannot accommodate the descriptor (for example, it is still an error to pass an INTEGER*2 item to an E edit descriptor).
`check output_conversion`	Issues the run-time OUTCONERR continuable error message when a data item is too large to fit in a designated format descriptor field without loss of significant digits. Format truncation occurs, the field is filled with asterisks (*), and execution continues.
`check pointers`	Enables run-time checking for disassociated or uninitialized Fortran pointers, unallocated allocatable objects, and integer pointers that are uninitialized.
`check uninit`	Enables run-time checking for uninitialized variables. If a variable is read before it is written, a run-time error routine will be called. Only local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, and LOGICAL without the SAVE attribute are checked.

Option	Description
`check all`	Enables all check options. This is the same as specifying `check` with no keyword.

To get more detailed location information about where an error occurred, use option `traceback`.

Alternate Options

`check none`	Linux and Mac OS X: `-nocheck` Windows: `/nocheck`, `/4Nb`
`check bounds`	Linux and Mac OS X: `-CB` Windows: `/CB`
`check uninit`	Linux and Mac OS X: `-CU` Windows: `/RTCu`, `/CU`
`check all`	Linux and Mac OS X: `-check, -C` Windows: `/check`, `/4Yb`, `/C`

compile-only

See c.

complex-limited-range, Qcomplex-limited-range

Determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

IDE Equivalent

Windows: **Floating point > Limit COMPLEX Range**

Linux: None

Mac OS X: **Floating point > Limit COMPLEX Range**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-complex-limited-range
-no-complex-limited-range
```

Windows:

```
/Qcomplex-limited-range
/Qcomplex-limited-range-
```

Arguments

None

Default

`-no-complex-limited-range` or `/Qcomplex-limited-range-`	Basic algebraic expansions of some arithmetic operations involving data of type COMPLEX are disabled.

Description

This option determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

When the option is enabled, this can cause performance improvements in programs that use a lot of COMPLEX arithmetic. However, values at the extremes of the exponent range may not compute correctly.

Alternate Options

None

convert

Specifies the format of unformatted files containing numeric data.

IDE Equivalent

Windows: **Compatibility > Unformatted File Conversion**

Linux: None

Mac OS X: **Compatibility > Unformatted File Conversion**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-convert` *keyword*

Windows:

`/convert:`*keyword*

Arguments

keyword

Specifies the format for the unformatted numeric data. Possible values are:

`native`	Specifies that unformatted data should not be converted.
`big_endian`	Specifies that the format will be big endian for integer data and big endian IEEE floating-point for real and complex data.
`cray`	Specifies that the format will be big endian for integer data and CRAY* floating-point for real and complex data.
`fdx` (Linux, Mac OS X)	Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, D_floating, and X_floating for real and complex data.
`fgx` (Linux, Mac OS X)	Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, G_floating, and X_floating for real and complex data.
`ibm`	Specifies that the format will be big endian for integer data and IBM* System\370 floating-point format for real and complex data.
`little_endian`	Specifies that the format will be little endian for integer data and little endian IEEE floating-point for real and complex data.
`vaxd`	Specifies that the format will be little endian for integer data, and VAX* processor floating-point format F_floating, D_floating, and H_floating for real and complex data.

`vaxg`	Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, G_floating, and H_floating for real and complex data.

Default

`convert native`	No conversion is performed on unformatted files containing numeric data.

Description

This option specifies the format of unformatted files containing numeric data.

Option	Description
`convert native`	Specifies that unformatted data should not be converted.
`convert big_endian`	Specifies that the format will be big endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and big endian IEEE floating-point for REAL*4, REAL*8, REAL*16, COMPLEX*8, COMPLEX*16, or COMPLEX*32.
`convert cray`	Specifies that the format will be big endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and CRAY* floating-point for REAL*8 or COMPLEX*16.
`convert fdx`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, D_floating for REAL*8 or COMPLEX*16, and X_floating for REAL*16 or COMPLEX*32.
`convert fgx`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, G_floating for REAL*8 or COMPLEX*16, and X_floating for REAL*16 or COMPLEX*32.
`convert ibm`	Specifies that the format will be big endian for INTEGER*1, INTEGER*2, or INTEGER*4, and IBM* System\370 floating-point format for REAL*4 or COMPLEX*8 (IBM short 4) and REAL*8 or COMPLEX*16 (IBM long 8).

Option	Description
`convert little_endian`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8 and little endian IEEE floating-point for REAL*4, REAL*8, REAL*16, COMPLEX*8, COMPLEX*16, or COMPLEX*32.
`convert vaxd`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, D_floating for REAL*8 or COMPLEX*16, and H_floating for REAL*16 or COMPLEX*32.
`convert vaxg`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, G_floating for REAL*8 or COMPLEX*16, and H_floating for REAL*16 or COMPLEX*32.

Alternate Options

None

cpp, Qcpp

See fpp, Qfpp.

CU

See check.

cxxlib

Determines whether the compile links using the C++ run-time libraries provided by gcc.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-cxxlib[=dir]`

`-cxxlib-nostd`

`-no-cxxlib`

Windows:

`None`

Arguments

dir	Is an optional top-level location for the gcc binaries and libraries.

Default

`-no-cxxlib`	The compiler uses the default run-time libraries and does not link to any additional C++ run-time libraries.

Description

This option determines whether the compile links using the C++ run-time libraries provided by gcc.

Option `-cxxlib-nostd` prevents the compiler from linking with the standard C++ library. It is only useful for mixed-language applications.

Alternate Options

None

-

Building Applications: Options for Interoperability

D

Defines a symbol name that can be associated with an optional value.

IDE Equivalent

Windows: **General > Preprocessor Definitions**

Preprocessor> Preprocessor Definitions

Preprocessor > Preprocessor Definitions to FPP only

Linux: None

Mac OS X: **Preprocessor > Preprocessor Definitions**

Preprocessor > Preprocessor Definitions to FPP only

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Dname[=value]`

Windows:

`/Dname[=value]`

Arguments

name	Is the name of the symbol.
value	Is an optional integer or an optional character string delimited by double quotes; for example, `Dname=string`.

Default

`noD`	Only default symbols or macros are defined.

Description

Defines a symbol name that can be associated with an optional value.
This definition is used during preprocessing.

If a *value* is not specified, *name* is defined as "1".

If you want to specify more than one definition, you must use separate D options.

If you specify noD, all preprocessor definitions apply only to fpp and not to Intel® Fortran conditional compilation directives. To use this option, you must also specify option fpp.

CAUTION. On Linux and Mac OS X systems, if you are not specifying a *value*, do not use D for *name*, because it will conflict with the –DD option.

Alternate Options

D	Linux and Mac OS X: None Windows: /define:*name[=value]*
noD	Linux and Mac OS X: -nodefine Windows: /nodefine

See Also

•

Building Applications: Predefined Preprocessor Symbols

d-lines, Qd-lines

Compiles debug statements.

IDE Equivalent

Windows: **Language > Compile Lines With D in Column 1**

Linux: None

Mac OS X: **Language > Compile Lines With D in Column 1**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-d-lines`

`-nod-lines`

Windows:

`/d-lines`

`/nod-lines`

`/Qd-lines`

Arguments

None

Default

`nod-lines`	Debug lines are treated as comment lines.

Description

This option compiles debug statements. It specifies that lines in fixed-format files that contain a D in column 1 (debug statements) should be treated as source code.

Alternate Options

Linux and Mac OS X: `-DD`

Windows: None

dbglibs

Tells the linker to search for unresolved references in a debug run-time library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/dbglibs`

`/nodbglibs`

Arguments

None

Default

`/nodbglibs`	The linker does not search for unresolved references in a debug run-time library.

Description

This option tells the linker to search for unresolved references in a debug run-time library.

The following table shows which options to specify for a debug run-time library:

Type of Library	Options Required	Alternate Option
Debug single-threaded	`/libs:static` `/dbglibs`	`/MLd` (this is a deprecated option)

Debug multithreaded	`/libs:static`
	`/threads`
	`/dbglibs`
		`/MTd`

Multithreaded debug DLLs	`/libs:dll`
	`/threads`
	`/dbglibs`
		`/MDd`

Debug Fortran QuickWin multi-thread applications	`/libs:qwin` `/dbglibs`	None

Type of Library	Options Required	Alternate Option
Debug Fortran standard graphics (QuickWin single-thread) applications	`/libs:qwins` `/dbglibs`	None

Alternate Options

None

See Also

- Building Applications: Specifying Consistent Library Types; Programming with Mixed Languages Overview

DD

See dlines, Qdlines.

debug (Linux* OS and Mac OS* X)

Enables or disables generation of debugging information.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-debug[keyword]`

Windows:

`None`

Arguments

keyword Is the type of debugging information to be generated. Possible values are:

`none`	Disables generation of debugging information.
`full` or `all`	Generates complete debugging information.
`minimal`	Generates line number information for debugging.
`[no]emit_column`	Determines whether the compiler generates column number information for debugging.
`[no]inline-debug-info`	Determines whether the compiler generates enhanced debug information for inlined code.
`[no]semantic-stepping`	Determines whether the compiler generates enhanced debug information useful for breakpoints and stepping.
`[no]variable-locations`	Determines whether the compiler generates enhanced debug information useful in finding scalar local variables.
`extended`	Sets keyword values `semantic-stepping` and `variable-locations`.

For information on the non-default settings for these keywords, see the Description section.

Default

`-debug none` No debugging information is generated.

Description

This option enables or disables generation of debugging information.

Note that if you turn debugging on, optimization is turned off.

Keywords `semantic-stepping`, `inline-debug-info`, `variable-locations`, and `extended` can be used in combination with each other. If conflicting keywords are used in combination, the last one specified on the command line has precedence.

Option	Description
`-debug none`	Disables generation of debugging information.
`-debug full` or `-debug all`	Generates complete debugging information. It is the same as specifying `-debug` with no keyword.
`-debug minimal`	Generates line number information for debugging.
`-debug emit_column`	Generates column number information for debugging.
`-debug inline-debug-info`	Generates enhanced debug information for inlined code. It provides more information to debuggers for function call traceback.
`-debug semantic-stepping`	Generates enhanced debug information useful for breakpoints and stepping. It tells the debugger to stop only at machine instructions that achieve the final effect of a source statement. For example, in the case of an assignment statement, this might be a store instruction that assigns a value to a program variable; for a function call, it might be the machine instruction that executes the call. Other instructions generated for those source statements are not displayed during stepping. This option has no impact unless optimizations have also been enabled.
`-debug variable-locations`	Generates enhanced debug information useful in finding scalar local variables. It uses a feature of the Dwarf object module known as "location lists". This feature allows the run-time locations of local scalar variables to be specified more accurately; that is, whether, at a given position in the code, a variable value is found in memory or a machine register.

Option	Description
`-debug extended`	Sets keyword values `semantic-stepping` and `variable-locations`. It also tells the compiler to include column numbers in the line information.

On Linux* systems, debuggers read debug information from executable images. As a result, information is written to object files and then added to the executable by the linker. On Mac OS* X systems, debuggers read debug information from object files. As a result, the executables don't contain any debug information. Therefore, if you want to be able to debug on these systems, you must retain the object files.

Alternate Options

For `debug full`, `-debug all`, or `-debug`	Linux and Mac OS X: `-g` Windows: `/debug:full`, `/debug:all`, or `/debug`
For `-debug inline-debug-info`	Linux and Mac OS X: `-inline-debug-info` (this is a deprecated option) Windows: None

See Also

-
- `debug` (Windows*)

Building Applications: Debugging Overview

debug (Windows* OS)

Enables or disables generation of debugging information.

IDE Equivalent

Windows: **General > Debug Information Format** (`/debug:minimal`, `/debug:full`)

Debug > Enable Parallel Debug Checks (`/debug:parallel`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/debug[:keyword]`

`/nodebug`

Arguments

keyword	Is the type of debugging information to be generated. Possible values are:	
	`none`	Generates no symbol table information.
	`full` or `all`	Generates complete debugging information.
	`minimal`	Generates line numbers and minimal debugging information.
	`partial`	Deprecated. Generates global symbol table information needed for linking.
	`[no]parallel` (i32, i64em)	Determines whether the compiler generates parallel debug code instrumentations useful for thread data sharing and reentrant call detection. For this setting to be effective, option `/Qopenmp` must be set.

For information on the non-default settings for these keywords, see the Description section.

Default

`/debug:none`	This is the default on the command line and for a release configuration in the IDE.
`/debug:full`	This is the default for a debug configuration in the IDE.

Description

This option enables or disables generation of debugging information. It is passed to the linker.

Note that if you turn debugging on, optimization is turned off.

If conflicting keywords are used in combination, the last one specified on the command line has precedence.

Option	Description
`/debug:none`	Disables generation of debugging information. It is the same as specifying /nodebug.
`/debug:full` or `/debug:all`	Generates complete debugging information. It produces symbol table information needed for full symbolic debugging of unoptimized code and global symbol information needed for linking. It is the same as specifying `/debug` with no keyword. If you specify `/debug:full` for an application that makes calls to C library routines and you need to debug calls into the C library, you should also specify `/dbglibs` to request that the appropriate C debug library be linked against.
`/debug:minimal`	Generates line number information for debugging. It produces global symbol information needed for linking, but not local symbol table information needed for debugging.
`/debug:partial`	Generates global symbol table information needed for linking, but not local symbol table information needed for debugging. This option is deprecated and is not available in the IDE.
`/debug:parallel`	Generates parallel debug code instrumentations needed for the thread data sharing and reentrant call detection of the Intel® Parallel Debugger Extension. This option is only available on IA-32 and Intel® 64 architectures.

Alternate Options

For `/debug:minimal`	Linux and Mac OS X: None Windows: `/Zd` (this is a deprecated option)
For `/debug:full` or `/debug`	Linux and Mac OS X: None Windows: `/Zi`, `/Z7`

See Also

- Debugging Fortran Programs

debug-parameters

Tells the compiler to generate debug information for PARAMETERs used in a program.

IDE Equivalent

Windows: **Debugging > Information for PARAMETER Constants**

Linux: None

Mac OS X: **Debug > Information for PARAMETER Constants**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-debug-parameters [keyword]`

`-nodebug-parameters`

Windows:

`/debug-parameters[:keyword]`

`/nodebug-parameters`

Arguments

keyword — Are the PARAMETERs to generate debug information for. Possible values are:

- `none` — Generates no debug information for any PARAMETERs used in the program. This is the same as specifying `nodebug-parameters`.
- `used` — Generates debug information for only PARAMETERs that have actually been referenced in the program. This is the default if you do not specify a *keyword*.
- `all` — Generates debug information for all PARAMETERs defined in the program.

Default

`nodebug-parameters` — The compiler generates no debug information for any PARAMETERs used in the program. This is the same as specifying *keyword* `none`.

Description

This option tells the compiler to generate debug information for PARAMETERs used in a program.

Note that if a .mod file contains PARAMETERs, debug information is only generated for the PARAMETERs that have actually been referenced in the program, even if you specify *keyword* `all`.

Alternate Options

None

define

See D.

diag, Qdiag

Controls the display of diagnostic information.

IDE Equivalent

Windows: **Diagnostics > Disable Specific Diagnostics** (`/Qdiag-disable:id`)

Diagnostics > Level of Source Code Analysis (`/Qdiag-enable[:sc1,sc2,sc3]`)

Linux: None

Mac OS X: **Diagnostics > Disable Specific Diagnostics** (`-diag-disable id`)

Diagnostics > Level of Source Code Analysis (`-diag-enable [sc1,sc2,sc3]`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-`*`type diag-list`*

Windows:

`/Qdiag-`*`type:diag-list`*

Arguments

`type`	Is an action to perform on diagnostics. Possible values are:	
	`enable`	Enables a diagnostic message or a group of messages.
	`disable`	Disables a diagnostic message or a group of messages.
	`error`	Tells the compiler to change diagnostics to errors.
	`warning`	Tells the compiler to change diagnostics to warnings.
	`remark`	Tells the compiler to change diagnostics to remarks (comments).
`diag-list`	Is a diagnostic group or ID value. Possible values are:	
	`driver`	Specifies diagnostic messages issued by the compiler driver.
	`vec`	Specifies diagnostic messages issued by the vectorizer.
	`par`	Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).

`openmp`	Specifies diagnostic messages issued by the OpenMP* parallelizer.
`sc[n]`	Specifies diagnostic messages issued by the Source Checker. *n* can be any of the following: 1, 2, 3. For more details on these values, see below. This value is equivalent to deprecated value sv[n].
`warn`	Specifies diagnostic messages that have a "warning" severity level.
`error`	Specifies diagnostic messages that have an "error" severity level.
`remark`	Specifies diagnostic messages that are remarks or comments.
`cpu-dispatch`	Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default. This diagnostic group is only available on IA-32 architecture and Intel® 64 architecture.
`id[,id,...]`	Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each id.
`tag[,tag,...]`	Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each tag.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option controls the display of diagnostic information. Diagnostic messages are output to stderr unless compiler option `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows) is specified.

When *diag-list* value "warn" is used with the Source Checker (sc) diagnostics, the following behavior occurs:

- Option `-diag-enable warn` (Linux and Mac OS X) and `/Qdiag-enable:warn` (Windows) enable all Source Checker diagnostics except those that have an "error" severity level. They enable all Source Checker warnings, cautions, and remarks.
- Option `-diag-disable warn` (Linux and Mac OS X) and `/Qdiag-disable:warn` (Windows) disable all Source Checker diagnostics except those that have an "error" severity level. They suppress all Source Checker warnings, cautions, and remarks.

The following table shows more information on values you can specify for diag-list item sc.

***diag-list* Item**	**Description**	
`sc[n]`	The value of *n* for Source Checker messages can be any of the following:	
	1	Produces the diagnostics with severity level set to all critical errors.
	2	Produces the diagnostics with severity level set to all errors. This is the default if n is not specified.
	3	Produces the diagnostics with severity level set to all errors and warnings.

To control the diagnostic information reported by the vectorizer, use the `-vec-report` (Linux and Mac OS X) or `/Qvec-report` (Windows) option.

To control the diagnostic information reported by the auto-parallelizer, use the `-par-report` (Linux and Mac OS X) or `/Qpar-report` (Windows) option.

Alternate Options

enable vec	Linux and Mac OS X: `-vec-report` Windows: `/Qvec-report`
disable vec	Linux and Mac OS X: `-vec-report0` Windows: `/Qvec-report0`

enable par	Linux and Mac OS X: `-par-report` Windows: `/Qpar-report`
disable par	Linux and Mac OS X: `-par-report0` Windows: `/Qpar-report0`

Example

The following example shows how to enable diagnostic IDs 117, 230 and 450:

```
-diag-enable 117,230,450     ! Linux and Mac OS X systems

/Qdiag-enable:117,230,450    ! Windows systems
```

The following example shows how to change vectorizer diagnostic messages to warnings:

```
-diag-enable vec -diag-warning vec      ! Linux and Mac OS X systems

/Qdiag-enable:vec /Qdiag-warning:vec    ! Windows systems
```

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.

The following example shows how to disable all auto-parallelizer diagnostic messages:

```
-diag-disable par     ! Linux and Mac OS X systems

/Qdiag-disable:par    ! Windows systems
```

The following example shows how to produce Source Checker diagnostic messages for all critical errors:

```
-diag-enable sc1      ! Linux and Mac OS X systems

/Qdiag-enable:sc1     ! Windows system
```

The following example shows how to cause Source Checker diagnostics (and default diagnostics) to be sent to a file:

```
-diag-enable sc -diag-file=stat_ver_msg   ! Linux and Mac OS X systems

/Qdiag-enable:sc /Qdiag-file:stat_ver_msg ! Windows systems
```

Note that you need to enable the Source Checker diagnostics before you can send them to a file. In this case, the diagnostics are sent to file stat_ver_msg.diag. If a file name is not specified, the diagnostics are sent to name-of-the-first-source-file.diag.

The following example shows how to change all diagnostic warnings and remarks to errors:

```
-diag-error warn,remark    ! Linux and Mac OS X systems

/Qdiag-error:warn,remark   ! Windows systems
```

- diag-file, Qdiag-file
- par-report, Qpar-report
- vec-report, Qvec-report

diag-dump, Qdiag-dump

Tells the compiler to print all enabled diagnostic messages and stop compilation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-diag-dump
```

Windows:

```
/Qdiag-dump
```

Arguments

None

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option tells the compiler to print all enabled diagnostic messages and stop compilation. The diagnostic messages are output to `stdout`.

This option prints the enabled diagnostics from all possible diagnostics that the compiler can issue, including any default diagnostics.

If `-diag-enable` *`diag-list`* (Linux and Mac OS X) or `/Qdiag-enable` *`diag-list`* (Windows) is specified, the print out will include the *`diag-list`* diagnostics.

Alternate Options

None

Example

The following example adds vectorizer diagnostic messages to the printout of default diagnostics:

```
-diag-enable vec -diag-dump         ! Linux and Mac OS X systems
/Qdiag-enable:vec /Qdiag-dump    ! Windows systems
```

See Also

-
- `diag, Qdiag`

diag, Qdiag

Controls the display of diagnostic information.

IDE Equivalent

Windows: **Diagnostics > Disable Specific Diagnostics** (`/Qdiag-disable:id`)

Diagnostics > Level of Source Code Analysis (`/Qdiag-enable[:sc1,sc2,sc3]`)

Linux: None

Mac OS X: **Diagnostics > Disable Specific Diagnostics** (`-diag-disable id`)

Diagnostics > Level of Source Code Analysis (`-diag-enable [sc1,sc2,sc3]`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-`*`type diag-list`*

Windows:

`/Qdiag-`*`type:diag-list`*

Arguments

type	Is an action to perform on diagnostics. Possible values are:	
	`enable`	Enables a diagnostic message or a group of messages.
	`disable`	Disables a diagnostic message or a group of messages.
	`error`	Tells the compiler to change diagnostics to errors.
	`warning`	Tells the compiler to change diagnostics to warnings.
	`remark`	Tells the compiler to change diagnostics to remarks (comments).
diag-list	Is a diagnostic group or ID value. Possible values are:	
	`driver`	Specifies diagnostic messages issued by the compiler driver.
	`vec`	Specifies diagnostic messages issued by the vectorizer.
	`par`	Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).
	`openmp`	Specifies diagnostic messages issued by the OpenMP* parallelizer.
	`sc[n]`	Specifies diagnostic messages issued by the Source Checker. *n* can be any of the following: 1, 2, 3. For more details on these values, see below. This value is equivalent to deprecated value sv[n].

`warn`	Specifies diagnostic messages that have a "warning" severity level.
`error`	Specifies diagnostic messages that have an "error" severity level.
`remark`	Specifies diagnostic messages that are remarks or comments.
`cpu-dispatch`	Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default. This diagnostic group is only available on IA-32 architecture and Intel® 64 architecture.
`id[,id,...]`	Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each id.
`tag[,tag,...]`	Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each tag.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option controls the display of diagnostic information. Diagnostic messages are output to stderr unless compiler option `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows) is specified.

When *`diag-list`* value "warn" is used with the Source Checker (sc) diagnostics, the following behavior occurs:

- Option `-diag-enable warn` (Linux and Mac OS X) and `/Qdiag-enable:warn` (Windows) enable all Source Checker diagnostics except those that have an "error" severity level. They enable all Source Checker warnings, cautions, and remarks.

- Option `-diag-disable warn` (Linux and Mac OS X) and `/Qdiag-disable:warn` (Windows) disable all Source Checker diagnostics except those that have an "error" severity level. They suppress all Source Checker warnings, cautions, and remarks.

The following table shows more information on values you can specify for diag-list item sc.

diag-list Item	Description	
`sc[n]`	The value of *n* for Source Checker messages can be any of the following:	
	1	Produces the diagnostics with severity level set to all critical errors.
	2	Produces the diagnostics with severity level set to all errors. This is the default if n is not specified.
	3	Produces the diagnostics with severity level set to all errors and warnings.

To control the diagnostic information reported by the vectorizer, use the `-vec-report` (Linux and Mac OS X) or `/Qvec-report` (Windows) option.

To control the diagnostic information reported by the auto-parallelizer, use the `-par-report` (Linux and Mac OS X) or `/Qpar-report` (Windows) option.

Alternate Options

enable vec	Linux and Mac OS X: `-vec-report` Windows: `/Qvec-report`
disable vec	Linux and Mac OS X: `-vec-report0` Windows: `/Qvec-report0`
enable par	Linux and Mac OS X: `-par-report` Windows: `/Qpar-report`
disable par	Linux and Mac OS X: `-par-report0` Windows: `/Qpar-report0`

Example

The following example shows how to enable diagnostic IDs 117, 230 and 450:

```
-diag-enable 117,230,450     ! Linux and Mac OS X systems
/Qdiag-enable:117,230,450    ! Windows systems
```

The following example shows how to change vectorizer diagnostic messages to warnings:

```
-diag-enable vec -diag-warning vec      ! Linux and Mac OS X systems

/Qdiag-enable:vec /Qdiag-warning:vec    ! Windows systems
```

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.

The following example shows how to disable all auto-parallelizer diagnostic messages:

```
-diag-disable par     ! Linux and Mac OS X systems

/Qdiag-disable:par    ! Windows systems
```

The following example shows how to produce Source Checker diagnostic messages for all critical errors:

```
-diag-enable sc1      ! Linux and Mac OS X systems

/Qdiag-enable:sc1     ! Windows system
```

The following example shows how to cause Source Checker diagnostics (and default diagnostics) to be sent to a file:

```
-diag-enable sc -diag-file=stat_ver_msg   ! Linux and Mac OS X systems

/Qdiag-enable:sc /Qdiag-file:stat_ver_msg ! Windows systems
```

Note that you need to enable the Source Checker diagnostics before you can send them to a file. In this case, the diagnostics are sent to file stat_ver_msg.diag. If a file name is not specified, the diagnostics are sent to name-of-the-first-source-file.diag.

The following example shows how to change all diagnostic warnings and remarks to errors:

```
-diag-error warn,remark    ! Linux and Mac OS X systems

/Qdiag-error:warn,remark   ! Windows systems
```

diag-enable sc-include, Qdiag-enable:sc-include

Tells a source code analyzer to process include files and source files when issuing diagnostic messages.

IDE Equivalent

Windows: **Diagnostics > Analyze Include Files**

Linux: None

Mac OS X: **Diagnostics > Analyze Include Files**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-diag-enable sc-include
```

Windows:

```
/Qdiag-enable:sc-include
```

Arguments

None

Default

OFF	The compiler issues certain diagnostic messages by default. If the Source Checker is enabled, include files are not analyzed by default.

Description

This option tells a source code analyzer (Source Checker) to process include files and source files when issuing diagnostic messages. Normally, when Source Checker diagnostics are enabled, only source files are analyzed.

To use this option, you must also specify `-diag-enable sc` (Linux and Mac OS X) or `/Qdiag-enable:sc` (Windows) to enable the Source Checker diagnostics, or `-diag-enable sc-parallel` (Linux and Mac OS X) or `/Qdiag-enable:sc-parallel` (Windows) to enable parallel lint.

Alternate Options

Linux and Mac OS X: `-diag-enable sv-include` (this is a deprecated option)

Windows: `/Qdiag-enable:sv-include` (this is a deprecated option)

Example

The following example shows how to cause include files to be analyzed as well as source files:

```
-diag-enable sc -diag-enable sc-include    ! Linux and Mac OS systems

/Qdiag-enable:sc /Qdiag-enable:sc-include  ! Windows systems
```

In the above example, the first compiler option enables Source Checker messages. The second compiler option causes include files referred to by the source file to be analyzed also.

See Also

-
-
- `diag-enable sc-parallel`, `Qdiag-enable:sc-parallel`
- `diag`, `Qdiag`

diag-enable sc-parallel, Qdiag-enable:sc-parallel

Enables analysis of parallelization in source code (parallel lint diagnostics).

IDE Equivalent

Windows: **Diagnostics > Level of Source Code Parallelization Analysis**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-diag-enable sc-parallel[n]`

Windows:

`/Qdiag-enable:sc-parallel[n]`

Arguments

n	Is the level of analysis to perform. Possible values are:
1	Produces the diagnostics with severity level set to all critical errors.
2	Tells the compiler to generate a report with the medium level of detail. Produces the diagnostics with severity level set to all errors. This is the default if *n* is not specified.
3	Produces the diagnostics with severity level set to all errors and warnings.

Default

OFF	The compiler does not analyze parallelization in source code.

Description

This option enables analysis of parallelization in source code (parallel lint diagnostics). Currently, this analysis uses OpenMP directives, so this option has no effect unless option `/Qopenmp` (Windows) or option `-openmp` (Linux and Mac OS X) is set.

Parallel lint performs interprocedural source code analysis to identify mistakes when using parallel directives. It reports various problems that are difficult to find, including data dependency and potential deadlocks.

Source Checker diagnostics (enabled by `/Qdiag-enable:sc` on Windows* OS or `-diag-enable sc` on Linux* OS and Mac OS* X) are a superset of parallel lint diagnostics. Therefore, if Source Checker diagnostics are enabled, the parallel lint option is not taken into account.

Alternate Options

None

See Also

-
-
- diag, Qdiag

diag-error-limit, Qdiag-error-limit

Specifies the maximum number of errors allowed before compilation stops.

IDE Equivalent

Windows: **Compilation Diagnostics > Error Limit**

Linux: None

Mac OS X: **Compiler Diagnostics > Error Limit**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-error-limit`*n*

`-no-diag-error-limit`

Windows:

`/Qdiag-error-limit:`*n*

`/Qdiag-error-limit-`

Arguments

n	Is the maximum number of error-level or fatal-level compiler errors allowed.

Default

30	A maximum of 30 error-level and fatal-level messages are allowed.

Description

This option specifies the maximum number of errors allowed before compilation stops. It indicates the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line.

If you specify `-no-diag-error-limit` (Linux and Mac OS X) or `/Qdiag-error-limit-` (Windows) on the command line, there is no limit on the number of errors that are allowed.

If the maximum number of errors is reached, a warning message is issued and the next file (if any) on the command line is compiled.

Alternate Options

Linux and Mac OS X: `-error-limit` and `-noerror-limit`

Windows: `/error-limit` and `/noerror-limit`

diag-file, Qdiag-file

Causes the results of diagnostic analysis to be output to a file.

IDE Equivalent

Windows: **Diagnostics > Diagnostics File**

Linux: None

Mac OS X: **Diagnostics > Diagnostics File**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-file[=`*`file`*`]`

Windows:

`/Qdiag-file[:`*`file`*`]`

Arguments

file	Is the name of the file for output.

Default

OFF	Diagnostic messages are output to stderr.

Description

This option causes the results of diagnostic analysis to be output to a file. The file is placed in the current working directory.

If *file* is specified, the name of the file is *file.diag*. The file can include a file extension; for example, if *file.ext* is specified, the name of the file is *file.ext*.

If *file* is not specified, the name of the file is *name-of-the-first-source-file.diag*. This is also the name of the file if the name specified for file conflicts with a source file name provided in the command line.

NOTE. If you specify `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows) and you also specify `-diag-file-append` (Linux and Mac OS X) or `/Qdiag-file-append` (Windows), the last option specified on the command line takes precedence.

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be output to a file named `my_diagnostics.diag`:

```
-diag-file=my_diagnostics       ! Linux and Mac OS X systems
/Qdiag-file:my_diagnostics      ! Windows systems
```

See Also

-
-
- diag, Qdiag
- diag-file-append, Qdiag-file-append

diag-file-append, Qdiag-file-append

Causes the results of diagnostic analysis to be appended to a file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-file-append[=file]`

Windows:

`/Qdiag-file-append[:file]`

Arguments

file	Is the name of the file to be appended to. It can include a path.

Default

OFF	Diagnostic messages are output to `stderr`.

Description

This option causes the results of diagnostic analysis to be appended to a file. If you do not specify a path, the driver will look for *file* in the current working directory.

If *file* is not found, then a new file with that name is created in the current working directory. If the name specified for file conflicts with a source file name provided in the command line. the name of the file is *name-of-the-first-source-file.diag*.

NOTE. If you specify `-diag-file-append` (Linux and Mac OS X) or `/Qdiag-file-append` (Windows) and you also specify `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows), the last option specified on the command line takes precedence.

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be appended to a file named my_diagnostics.txt:

```
-diag-file-append=my_diagnostics.txt       ! Linux and Mac OS X systems
/Qdiag-file-append:my_diagnostics.txt      ! Windows systems
```

See Also

-
-
- diag, Qdiag
- diag-file, Qdiag-file

diag-id-numbers, Qdiag-id-numbers

Determines whether the compiler displays diagnostic messages by using their ID number values.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-diag-id-numbers
-no-diag-id-numbers
```

Windows:

```
/Qdiag-id-numbers
/Qdiag-id-numbers-
```

Arguments

None

Default

`-diag-id-numbers` or `/Qdiag-id-numbers`	The compiler displays diagnostic messages by using their ID number values.

Description

This option determines whether the compiler displays diagnostic messages by using their ID number values. If you specify `-no-diag-id-numbers` (Linux and Mac OS X) or `/Qdiag-id-numbers-` (Windows), mnemonic names are output for driver diagnostics only.

Alternate Options

None

See Also

-
-
- `diag`, `Qdiag`

diag-once, Qdiag-once

Tells the compiler to issue one or more diagnostic messages only once.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-once`*`id`*`[,`*`id`*`,...]`

Windows:

`/Qdiag-once:id[,id,...]`

Arguments

id	Is the ID number of the diagnostic message. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each *id*.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option tells the compiler to issue one or more diagnostic messages only once.

Alternate Options

None

dll

Specifies that a program should be linked as a dynamic-link (DLL) library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/dll`

Arguments

None

Default

OFF	The program is not linked as a dynamic-link (DLL) library.

Description

This option specifies that a program should be linked as a dynamic-link (DLL) library instead of an executable (.exe) file. It overrides any previous specification of run-time routines to be used and enables the `/libs:dll` option.

If you use this option with the `/libs:qwin` or `/libs:qwins` option, the compiler issues a warning.

Alternate Options

Linux and Mac OS X: None

Windows: `/LD`

double-size

Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX variables.

IDE Equivalent

Windows: **Data > Default Double Precision KIND**

Linux: None

Mac OS X: **Data > Default Double Precision KIND**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-double-size` *size*

Windows:

`/double-size:`*`size`*

Arguments

`size`	Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics. Possible values are: 64 (KIND=8) or 128 (KIND=16).

Default

64	DOUBLE PRECISION variables are defined as REAL*8 and DOUBLE COMPLEX variables are defined as COMPLEX*16.

Description

This option defines the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics.

Option	Description
`double-size 64`	Defines DOUBLE PRECISION declarations, constants, functions, and intrinsics as REAL(KIND=8) (REAL*8) and defines DOUBLE COMPLEX declarations, functions, and intrinsics as COMPLEX(KIND=8) (COMPLEX*16).
`double-size 128`	Defines DOUBLE PRECISION declarations, constants, functions, and intrinsics as REAL(KIND=16) (REAL*16) and defines DOUBLE COMPLEX declarations, functions, and intrinsics as COMPLEX(KIND=16) (COMPLEX*32).

Alternate Options

None

dps, Qdps

See altparam.

dryrun

Specifies that driver tool commands should be shown but not executed.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-dryrun`

Windows:

`None`

Arguments

None

Default

OFF	No tool commands are shown, but they are executed.

Description

This option specifies that driver tool commands should be shown but not executed.

Alternate Options

None

See Also

-
- v

dumpmachine

Displays the target machine and operating system configuration.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-dumpmachine`

Windows:

`None`

Arguments

None

Default

OFF	The compiler does not display target machine or operating system information.

Description

This option displays the target machine and operating system configuration. No compilation is performed.

Alternate Options

None

dynamic-linker

Specifies a dynamic linker other than the default.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-dynamic-linker` *`file`*

Mac OS X:

`None`

Windows:

`None`

Arguments

`file`	Is the name of the dynamic linker to be used.

Default

OFF	The default dynamic linker is used.

Description

This option lets you specify a dynamic linker other than the default.

Alternate Options

None

dynamiclib

Invokes the `libtool` *command to generate dynamic libraries.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux:

`None`

Mac OS X:

`-dynamiclib`

Windows:

`None`

Arguments

None

Default

OFF	The compiler produces an executable.

Description

This option invokes the `libtool` command to generate dynamic libraries.

When passed this option, the compiler uses the `libtool` command to produce a dynamic library instead of an executable when linking.

To build static libraries, you should specify option `-staticlib` or `libtool -static <objects>`.

Alternate Options

None

See Also

-
- staticlib

dyncom, Qdyncom

Enables dynamic allocation of common blocks at run time.

IDE Equivalent

Windows: **Data > Dynamic Common Blocks**

Linux: None

Mac OS X: **Data > Dynamic Common Blocks**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-dyncom "`*`common1`*`,`*`common2`*`,..."`

Windows:

`/Qdyncom "`*`common1`*`,`*`common2`*`,..."`

Arguments

`common1``,`*`common2`*`,...`	Are the names of the common blocks to be dynamically allocated. The list of names must be within quotes.

Default

OFF	Common blocks are not dynamically allocated at run time.

Description

This option enables dynamic allocation of the specified common blocks at run time. For example, to enable dynamic allocation of common blocks a, b, and c at run time, use this syntax:

```
/Qdyncom "a,b,c"    ! on Windows systems

-dyncom "a,b,c"     ! on Linux and Mac OS X systems
```

The following are some limitations that you should be aware of when using this option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
- Only named common blocks can be designated as dynamic COMMON.
- An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

Alternate Options

None

See Also

-
-

Building Applications: Allocating Common Blocks

E

Causes the preprocessor to send output to `stdout`.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-E`

Windows:

`/E`

Arguments

None

Default

OFF	Preprocessed source files are output to the compiler.

Description

This option causes the preprocessor to send output to `stdout`. Compilation stops when the files have been preprocessed.

When you specify this option, the compiler's preprocessor expands your source module and writes the result to `stdout`. The preprocessed source contains #line directives, which the compiler uses to determine the source file and line number.

Alternate Options

None

e90, e95, e03

See warn.

EP

Causes the preprocessor to send output to `stdout`*, omitting #line directives.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-EP`

Windows:

`/EP`

Arguments

None

Default

OFF	Preprocessed source files are output to the compiler.

Description

This option causes the preprocessor to send output to `stdout`, omitting #line directives.

If you also specify option `preprocess-only`, option `P`, or option `F`, the preprocessor will write the results (without #line directives) to a file instead of `stdout`.

Alternate Options

None

error-limit

See diag-error-limit, Qdiag-error-limit.

exe

Specifies the name for a built program or dynamic-link library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/exe:{`*`file | dir`*`}`

Arguments

`file`	Is the name for the built program or dynamic-link library.
`dir`	Is the directory where the built program or dynamic-link library should be placed. It can include *`file`*.

Default

OFF	The name of the file is the name of the first source file on the command line with file extension .exe, so file.f becomes file.exe.

Description

This option specifies the name for a built program (.EXE) or a dynamic-link library (.DLL).

You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.

You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.

Alternate Options

Linux and Mac OS X: `-o`

Windows: /Fe

Example

The following example creates a dynamic-link library file named file.dll (note that you can use `/LD` in place of `/dll`):

```
ifort /dll /exe:file.dll a.f
```

In the following example (which uses the alternate option `/Fe`), the command produces an executable file named outfile.exe as a result of compiling and linking three files: one object file and two Fortran source files.

```
prompt>ifort /Feoutfile.exe file1.obj file2.for file3.for
```

By default, this command produces an executable file named file1.exe.

-
- o

extend-source

Specifies the length of the statement field in a fixed-form source file.

IDE Equivalent

Windows: **Language > Fixed Form Line Length**

Linux: None

Mac OS X: **Language > Fixed Form Line Length**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-extend-source [size]`

`-noextend-source`

Windows:

`/extend-source[:size]`

`/noextend-source`

Arguments

size	Is the length of the statement field in a fixed-form source file. Possible values are: 72, 80, or 132.

Default

72	If you do not specify this option or you specify `noextend-source`, the statement field ends at column 72.
132	If you specify `extend_source` without *size*, the statement field ends at column 132.-

Description

This option specifies the size (column number) of the statement field of a source line in a fixed-form source file. This option is valid only for fixed-form files; it is ignored for free-form files.

When size is specified, it is the last column parsed as part of the statement field. Any columns after that are treated as comments.

If you do not specify *size*, it is the same as specifying `extend_source 132`.

Option	Description
`extend-source 72`	Specifies that the statement field ends at column 72.
`extend-source 80`	Specifies that the statement field ends at column 80.
`extend-source 132`	Specifies that the statement field ends at column 132.

Alternate Options

`extend-source 72`	Linux and Mac OS X: `-72` Windows: `/4L72`
`extend-source 80`	Linux and Mac OS X: `-80` Windows: `/4L80`
`extend-source 132`	Linux and Mac OS X: `-132` Windows: `/Qextend-source, /4L132`

extfor

Specifies file extensions to be processed by the compiler as Fortran files.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/extfor:`*`ext`*

Arguments

`ext`	Are the file extensions to be processed as a Fortran file.

Default

OFF	Only the file extensions recognized by the compiler are processed as Fortran files. For more information, see *Building Applications*.

Description

This option specifies file extensions (*`ext`*) to be processed by the compiler as Fortran files. It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extfor:myf95` and `/extfor:.myf95` are equivalent.

Alternate Options

None

See Also

-
- source compiler option

extfpp

Specifies file extensions to be recognized as a file to be preprocessed by the Fortran preprocessor.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/extfpp:`*`ext`*

Arguments

`ext`	Are the file extensions to be preprocessed by the Fortran preprocessor.

Default

OFF	Only the file extensions recognized by the compiler are preprocessed by `fpp`. For more information, see *Building Applications*.

Description

This option specifies file extensions (*`ext`*) to be recognized as a file to be preprocessed by the Fortran preprocessor (`fpp`). It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extfpp:myfpp` and `/extfpp:.myfpp` are equivalent.

Alternate Options

None

extlnk

Specifies file extensions to be passed directly to the linker.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/extlnk:`*`ext`*

Arguments

`ext`	Are the file extensions to be passed directly to the linker.

Default

OFF	Only the file extensions recognized by the compiler are passed to the linker. For more information, see Building Applications.

Description

This option specifies file extensions (*`ext`*) to be passed directly to the linker. It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extlnk:myobj` and `/extlnk:.myobj` are equivalent.

Alternate Options

None

F (Windows*)

Specifies the stack reserve amount for the program.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Fn`

Arguments

n	Is the stack reserve amount. It can be specified as a decimal integer or by using a C-style convention for constants (for example, /F0x1000).

Default

OFF	The stack size default is chosen by the operating system.

Description

This option specifies the stack reserve amount for the program. The amount (*n*) is passed to the linker.

Note that the linker property pages have their own option to do this.

Alternate Options

None

f66

Tells the compiler to apply FORTRAN 66 semantics.

IDE Equivalent

Windows: **Language > Enable FORTRAN 66 Semantics**

Linux: None

Mac OS X: **Language > Enable FORTRAN 66 Semantics**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-f66`

Windows:

`/f66`

Arguments

None

Default

OFF	The compiler applies Fortran 95 semantics.

Description

This option tells the compiler to apply FORTRAN 66 semantics when interpreting language features. This causes the following to occur:

- DO loops are always executed at least once
- FORTRAN 66 EXTERNAL statement syntax and semantics are allowed
- If the OPEN statement STATUS specifier is omitted, the default changes to STATUS='NEW' instead of STATUS='UNKNOWN'
- If the OPEN statement BLANK specifier is omitted, the default changes to BLANK='ZERO' instead of BLANK='NULL'

Alternate Options

Linux and Mac OS X: `-66`

Windows: None

f77rtl

Tells the compiler to use the run-time behavior of FORTRAN 77.

IDE Equivalent

Windows: **Compatibility > Enable F77 Run-Time Compatibility**

Linux: None

Mac OS X: **Compatibility > Enable F77 Run-Time Compatibility**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-f77rtl`

`-nof77rtl`

Windows:

`/f77rtl`

`/nof77rtl`

Arguments

None

Default

`nof77rtl`	The compiler uses the run-time behavior of Intel® Fortran.

Description

This option tells the compiler to use the run-time behavior of FORTRAN 77.

Specifying this option controls the following run-time behavior:

- When the unit is not connected to a file, some INQUIRE specifiers will return different values:
  - NUMBER= returns 0

  - ACCESS= returns 'UNKNOWN'
  - BLANK= returns 'UNKNOWN'
  - FORM= returns 'UNKNOWN'
- PAD= defaults to 'NO' for formatted input.
- NAMELIST and list-directed input of character strings must be delimited by apostrophes or quotes.
- When processing NAMELIST input:
  - Column 1 of each record is skipped.
  - The '$' or '&' that appears prior to the group-name must appear in column 2 of the input record.

Alternate Options

None

Fa

See asmfile

FA

See asmattr

falias

Determines whether aliasing should be assumed in the program.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-falias
```

`-fno-alias`

Windows:

`None`

Arguments

None

Default

`-falias`	Aliasing is assumed in the program.

Description

This option determines whether aliasing should be assumed in the program.

If you do not want aliasing to be assumed in the program, specify `-fno-alias`.

Alternate Options

Linux and Mac OS X: None

Windows: `/Oa[-]`

See Also

-
- `ffnalias`

falign-functions, Qfnalign

Tells the compiler to align functions on an optimal byte boundary.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-falign-functions[=n]`

`-fno-align-functions`

Windows:

`/Qfnalign[:n]`

`/Qfnalign-`

Arguments

n	Is the byte boundary for function alignment. Possible values are 2 or 16.

Default

`-fno-align-functions` or `/Qfnalign-`	The compiler aligns functions on 2-byte boundaries. This is the same as specifying `-falign-functions=2` (Linux and Mac OS X) or `/Qfnalign:2` (Windows).

Description

This option tells the compiler to align functions on an optimal byte boundary. If you do not specify *n*, the compiler aligns the start of functions on 16-byte boundaries.

Alternate Options

None

falign-stack

Tells the compiler the stack alignment to use on entry to routines.

IDE Equivalent

None

Architectures

IA-32 architecture

Syntax

Linux and Mac OS X:

`-falign-stack=`*mode*

Windows:

None

Arguments

mode	Is the method to use for stack alignment. Possible values are:
`default`	Tells the compiler to use default heuristics for stack alignment. If alignment is required, the compiler dynamically aligns the stack.
`maintain-16-byte`	Tells the compiler to not assume any specific stack alignment, but attempt to maintain alignment in case the stack is already aligned. If alignment is required, the compiler dynamically aligns the stack. This setting is compatible with GCC.
`assume-16-byte`	Tells the compiler to assume the stack is aligned on 16-byte boundaries and continue to maintain 16-byte alignment. This setting is compatible with GCC.

Default

`-falign-stack=default`	The compiler uses default heuristics for stack alignment.

Description

This option tells the compiler the stack alignment to use on entry to routines.

Alternate Options

None

fast

Maximizes speed across the entire program.

IDE Equivalent

Windows: None

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fast`

Windows:

`/fast`

Arguments

None

Default

OFF	The optimizations that maximize speed are not enabled.

Description

This option maximizes speed across the entire program.

It sets the following options:

- On systems using IA-64 architecture:
  Windows: `/O3` and `/Qipo`
  Linux: `-ipo`, `-O3`, and `-static`
- On systems using IA-32 architecture and Intel® 64 architecture:
  Mac OS X: `-ipo`, `-mdynamic-no-pic`, `-O3`, `-no-prec-div`, `-static`, and `-xHost`
  Windows: `/O3`, `/Qipo`, `/Qprec-div-`, and `/QxHost`
  Linux: `-ipo`, `-O3`, `-no-prec-div`, `-static`, and `-xHost`

When option `fast` is specified on systems using IA-32 architecture or Intel® 64 architecture, you can override the `-xHost` or `/QxHost` setting by specifying a different processor-specific `-x` or `/Qx` option on the command line. However, the last option specified on the command line takes precedence.

For example, if you specify `-fast -xSSE3` (Linux) or `/fast /QxSSE3` (Windows), option `-xSSE3` or `/QxSSE3` takes effect. However, if you specify `-xSSE3 -fast` (Linux) or `/QxSSE3 /fast` (Windows), option `-xHost` or `/QxHost` takes effect.

NOTE. The options set by option `fast` may change from release to release.

Alternate Options

None

See Also

-
- x, Qx

fast-transcendentals, Qfast-transcendentals

Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-fast-transcendentals
-no-fast-transcendentals
```

Windows:

`/Qfast-transcendentals`

`/Qfast-transcendentals-`

Default

`-fast-transcendentals` or `/Qfast-transcendentals`	The default depends on the setting of `-fp-model` (Linux and Mac OS X) or `/fp` (Windows). The default is ON if default setting `-fp-model fast` or `/fp:fast` is in effect. However, if a value-safe option such as `-fp-model precise` or `/fp:precise` is specified, the default is OFF.

Description

This option enables the compiler to replace calls to transcendental functions with implementations that may be faster but less precise.

It tells the compiler to perform certain optimizations on transcendental functions, such as replacing individual calls to sine in a loop with a single call to a less precise vectorized sine library routine.

This option has an effect only when specified with one of the following options:

- Windows* OS: `/fp:except` or `/fp:precise`
- Linux* OS and Mac OS* X: `-fp-model except` or `-fp-model precise`

You cannot use this option with option `-fp-model strict` (Linux and Mac OS X) or `/fp:strict` (Windows).

Alternate Options

None

See Also

-
-
- `fp-model, fp`

fcode-asm

Produces an assembly listing with machine code annotations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fcode-asm`

Windows:

`None`

Arguments

None

Default

OFF	No machine code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with machine code annotations.

The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the filename is the name of the source file with an extension of `.cod`.

To use this option, you must also specify option `-S`, which causes an assembly listing to be generated.

Alternate Options

Linux and Mac OS X: None

Windows: `/asmattr:machine`

fexceptions

Enables exception handling table generation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fexceptions`

`-fno-exceptions`

Windows:

`None`

Arguments

None

Default

-fno-exceptions	Exception handling table generation is disabled.

Description

This option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines. The `-fno-exceptions` option disables C++ exception handling table generation, resulting in

smaller code. When this option is used, any use of C++ exception handling constructs (such as try blocks and throw statements) when a Fortran routine is in the call chain will produce an error.

Alternate Options

None

ffnalias

Specifies that aliasing should be assumed within functions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ffnalias`

`-fno-fnalias`

Windows:

`None`

Arguments

None

Default

-ffnalias	Aliasing is assumed within functions.

Description

This option specifies that aliasing should be assumed within functions.

The `-fno-fnalias` option specifies that aliasing should not be assumed within functions, but should be assumed across calls.

Alternate Options

Linux and Mac OS X: None

Windows: `/Ow[-]`

-
- falias

FI

See fixed.

finline

Tells the compiler to inline functions declared with cDEC$ ATTRIBUTES FORCEINLINE.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-finline`

`-fno-inline`

Windows:

`None`

Arguments

None

Default

`-fno-inline`	The compiler does not inline functions declared with cDEC$ ATTRIBUTES FORCEINLINE.

Description

This option tells the compiler to inline functions declared with cDEC$ ATTRIBUTES FORCEINLINE.

Alternate Options

None

finline-functions

Enables function inlining for single file compilation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-finline-functions`

`-fno-inline-functions`

Windows:

`None`

Arguments

None

Default

`-finline-functions`	Interprocedural optimizations occur. However, if you specify `-O0`, the default is OFF.

Description

This option enables function inlining for single file compilation.

It enables the compiler to perform inline function expansion for calls to functions defined within the current source file.

The compiler applies a heuristic to perform the function expansion. To specify the size of the function to be expanded, use the `-finline-limit` option.

Alternate Options

Linux and Mac OS X: `-inline-level=2`

Windows: `/Ob2`

See Also

-
- `ip`, `Qip`
- `finline-limit`
- Compiler Directed Inline Expansion of User Functions
- Inline Function Expansion

finline-limit

Lets you specify the maximum size of a function to be inlined.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-finline-limit=`*n*

Windows:

`None`

Arguments

n	Must be an integer greater than or equal to zero. It is the maximum number of lines the function can have to be considered for inlining.

Default

OFF	The compiler uses default heuristics when inlining functions.

Description

This option lets you specify the maximum size of a function to be inlined. The compiler inlines smaller functions, but this option lets you inline large functions. For example, to indicate a large function, you could specify 100 or 1000 for *n*.

Note that parts of functions cannot be inlined, only whole functions.

This option is a modification of the `-finline-functions` option, whose behavior occurs by default.

Alternate Options

None

See Also

-
- `finline-functions`

finstrument-functions, Qinstrument-functions

Determines whether routine entry and exit points are instrumented.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-finstrument-functions
-fno-instrument-functions
```

Windows:

```
/Qinstrument-functions
```

`/Qinstrument-functions-`

Arguments

None

Default

`-fno-instrument-functions` or `/Qinstrument-functions-`	Routine entry and exit points are not instrumented.

Description

This option determines whether routine entry and exit points are instrumented. It may increase execution time.

The following profiling functions are called with the address of the current routine and the address of where the routine was called (its "call site"):

- This function is called upon routine entry:
  - On IA-32 architecture and Intel® 64 architecture:

    ```
    void __cyg_profile_func_enter (void *this_fn,
    void *call_site);
    ```

  - On IA-64 architecture:

    ```
    void __cyg_profile_func_enter (void **this_fn,
    void *call_site);
    ```

- This function is called upon routine exit:
  - On IA-32 architecture and Intel® 64 architecture:

    ```
    void __cyg_profile_func_exit (void *this_fn,
    void *call_site);
    ```

  - On IA-64 architecture:

    ```
    void __cyg_profile_func_exit (void **this_fn,
    void *call_site);
    ```

On IA-64 architecture, the additional de-reference of the function pointer argument is required to obtain the routine entry point contained in the first word of the routine descriptor for indirect routine calls. The descriptor is documented in the Intel® Itanium® Software Conventions and Runtime Architecture Guide, section 8.4.2. You can find this design guide at web site http://www.intel.com.

These functions can be used to gather more information, such as profiling information or timing information. Note that it is the user's responsibility to provide these profiling functions.

If you specify `-finstrument-functions` (Linux and Mac OS X) or `/Qinstrument-functions` (Windows), routine inlining is disabled. If you specify `-fno-instrument-functions` or `/Qinstrument-functions-`, inlining is not disabled.

This option is provided for compatibility with gcc.

Alternate Options

None

fixed

Specifies source files are in fixed format.

IDE Equivalent

Windows: **Language > Source File Format** (`/free`, `/fixed`)

Linux: None

Mac OS X: **Language > Source File Format** (`/free`, `/fixed`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fixed`

`-nofixed`

Windows:

`/fixed`

`/nofixed`

Arguments

None

Default

OFF	The source file format is determined from the file extension.

Description

This option specifies source files are in fixed format. If this option is not specified, format is determined as follows:

- Files with an extension of .f90, .F90, or .i90 are free-format source files.
- Files with an extension of .f, .for, .FOR, .ftn, .FTN, .fpp, .FPP, or .i are fixed-format files.

Note that on Linux and Mac OS X systems, file names and file extensions are case sensitive.

Alternate Options

Linux and Mac OS X: `-FI`

Windows: `/nofree`, `/FI`, `/4Nf`

fkeep-static-consts, Qkeep-static-consts

Tells the compiler to preserve allocation of variables that are not referenced in the source.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-fkeep-static-consts
-fno-keep-static-consts
```

Windows:

`/Qkeep-static-consts`

`/Qkeep-static-consts-`

Arguments

None

Default

`-fno-keep-static-consts` or `/Qkeep-static-consts-`	If a variable is never referenced in a routine, the variable is discarded unless optimizations are disabled by option `-O0` (Linux and Mac OS X) or `/Od` (Windows).

Description

This option tells the compiler to preserve allocation of variables that are not referenced in the source.

The negated form can be useful when optimizations are enabled to reduce the memory usage of static data.

Alternate Options

None

fltconsistency

Enables improved floating-point consistency.

IDE Equivalent

Windows: **Floating-Point > Floating-Point Consistency**

Linux: None

Mac OS X: **Floating-Point > Improve Floating-Point Consistency**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fltconsistency`

`-nofltconsistency`

Windows:

`/fltconsistency`

`/nofltconsistency`

Arguments

None

Default

`nofltconsistency`	Improved floating-point consistency is not enabled. This setting provides better accuracy and run-time performance at the expense of less consistent floating-point results.

Description

This option enables improved floating-point consistency and may slightly reduce execution speed. It limits floating-point optimizations and maintains declared precision. It also disables inlining of math library functions.

Floating-point operations are not reordered and the result of each floating-point operation is stored in the target variable rather than being kept in the floating-point processor for use in a subsequent calculation.

For example, the compiler can change floating-point division computations into multiplication by the reciprocal of the denominator. This change can alter the results of floating-point division computations slightly.

Floating-point intermediate results are kept in full 80 bits internal precision. Additionally, all spills/reloads of the X87 floating point registers are done using the internal formats; this prevents accidental loss of precision due to spill/reload behavior over which you have no control.

Specifying this option has the following effects on program compilation:

- On systems using IA-32 architecture or Intel® 64 architecture, floating-point user variables are not assigned to registers.

- On systems using IA-64 architecture, floating-point user variables may be assigned to registers. The expressions are evaluated using precision of source operands. The compiler will not use the Floating-point Multiply and Add (FMA) function to contract multiply and add/subtract operations in a single operation. The contractions can be enabled by using `-fma` (Linux) or `/Qfma` (Windows) option. The compiler will not speculate on floating-point operations that may affect the floating-point state of the machine.
- Floating-point arithmetic comparisons conform to IEEE 754.
- The exact operations specified in the code are performed. For example, division is never changed to multiplication by the reciprocal.
- The compiler performs floating-point operations in the order specified without reassociation.
- The compiler does not perform constant folding on floating-point values. Constant folding also eliminates any multiplication by 1, division by 1, and addition or subtraction of 0. For example, code that adds 0.0 to a number is executed exactly as written. Compile-time floating-point arithmetic is not performed to ensure that floating-point exceptions are also maintained.
- Whenever an expression is spilled, it is spilled as 80 bits (extended precision), not 64 bits (DOUBLE PRECISION). When assignments to type REAL and DOUBLE PRECISION are made, the precision is rounded from 80 bits down to 32 bits (REAL) or 64 bits (DOUBLE PRECISION). When you do not specify `/Op`, the extra bits of precision are not always rounded away before the variable is reused.
- Even if vectorization is enabled by the `-x` (Linux and Mac OS X) or `/Qx` (Windows) options, the compiler does not vectorize reduction loops (loops computing the dot product) and loops with mixed precision types. Similarly, the compiler does not enable certain loop transformations. For example, the compiler does not transform reduction loops to perform partial summation or loop interchange.

This option causes performance degradation relative to using default floating-point optimization flags.

On Windows systems, an alternative is to use the `/Qprec` option, which should provide better than default floating-point precision while still delivering good floating-point performance.

The recommended method to control the semantics of floating-point calculations is to use option `-fp-model` (Linux and Mac OS X) or `/fp` (Windows).

Alternate Options

`fltconsistency`	Linux and Mac OS X: `-mp` (this is a deprecated option), `-mieee-fp`

	Windows: `/Op` (this is a deprecated option)
`nofltconsistency`	Linux and Mac OS X: `-mno-ieee-fp` Windows: None

Building Applications: Using Compiler Optimizations

Fm

This option has been deprecated.
See map.

fma, Qfma

Enables the combining or contraction of floating-point multiplications and add or subtract operations.

IDE Equivalent

Windows: **Floating Point > Contract Floating-Point Operations**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux:

`-fma`

`-no-fma`

Mac OS X:

`None`

Windows:

`/Qfma`

`/Qfma-`

Arguments

None

Default

`-fma` or `/Qfma`	Floating-point multiplications and add/subtract operations are combined. However, if you specify `-fp-model strict` (Linux) or `/fp:strict` (Windows), but do not explicitly specify `-fma` or `/Qfma`, the default is `-no-fma` or `/Qfma-`.

Description

This option enables the combining or contraction of floating-point multiplications and add or subtract operations into a single operation.

Alternate Options

Linux: `-IPF-fma` (this is a deprecated option)

Windows: `/QIPF-fma` (this is a deprecated option)

- `fp-model, fp`

Floating-point Operations: Floating-point Options Quick Reference

fmath-errno

Tells the compiler that `errno` *can be reliably tested after calls to standard math library functions.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fmath-errno`

`-fno-math-errno`

Windows:

`None`

Arguments

None

Default

`-fno-math-errno`	The compiler assumes that the program does not test `errno` after calls to standard math library functions.

Description

This option tells the compiler to assume that the program tests `errno` after calls to math library functions. This restricts optimization because it causes the compiler to treat most math functions as having side effects.

Option `-fno-math-errno` tells the compiler to assume that the program does not test `errno` after calls to math library functions. This frequently allows the compiler to generate faster code. Floating-point code that relies on IEEE exceptions instead of `errno` to detect errors can safely use this option to improve performance.

Alternate Options

None

fminshared

Specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fminshared`

Windows:

`None`

Arguments

None

Default

OFF	Source files are compiled together to form a single object file.

Description

This option specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

This option allows the compiler to optimize references to defined symbols without special visibility settings. To ensure that external and common symbol references are optimized, you need to specify visibility hidden or protected by using the `-fvisibility`, `-fvisibility-hidden`, or `-fvisibility-protected` option.

Also, the compiler does not need to generate position-independent code for the main program. It can use absolute addressing, which may reduce the size of the global offset table (GOT) and may reduce memory traffic.

Alternate Options

None

See Also

-
- `fvisibility`

fnsplit, Qfnsplit

Enables function splitting.

IDE Equivalent

None

Architectures

`/Qfnsplit[-]`: IA-32 architecture, Intel® 64 architecture

`-[no-]fnsplit`: IA-64 architecture

Syntax

Linux:

```
-fnsplit
-no-fnsplit
```

Mac OS X:

```
None
```

Windows:

```
/Qfnsplit
/Qfnsplit-
```

Arguments

None

Default

`-no-fnsplit` or `/Qfnsplit-`	Function splitting is not enabled unless `-prof-use` (Linux) or `/Qprof-use` (Windows) is also specified.

Description

This option enables function splitting if `-prof-use` (Linux) or `/Qprof-use` (Windows) is also specified. Otherwise, this option has no effect.

It is enabled automatically if you specify `-prof-use` or `/Qprof-use`. If you do not specify one of those options, the default is `-no-fnsplit` (Linux) or `/Qfnsplit-` (Windows), which disables function splitting but leaves function grouping enabled.

To disable function splitting when you use `-prof-use` or `/Qprof-use`, specify `-no-fnsplit` or `/Qfnsplit-`.

Alternate Options

None

fomit-frame-pointer, Oy

Determines whether EBP is used as a general-purpose register in optimizations.

IDE Equivalent

Windows: **Optimization > Omit Frame Pointers**

Linux: None

Mac OS X: **Optimization > Provide Frame Pointer**

Architectures

`-f[no-]omit-frame-pointer`: IA-32 architecture, Intel® 64 architecture

`/Oy[-]`: IA-32 architecture

Syntax

Linux and Mac OS X:

`-fomit-frame-pointer`

`-fno-omit-frame-pointer`

Windows:

`/Oy`

`/Oy-`

Arguments

None

Default

`-fomit-frame-pointer` or `/Oy`	EBP is used as a general-purpose register in optimizations. However, on Linux* and Mac OS X systems, the default is `-fno-omit-frame-pointer` if option `-O0` or `-g` is specified. On Windows* systems, the default is `/Oy-` if option `/Od` is specified.

Description

These options determine whether EBP is used as a general-purpose register in optimizations. Options `-fomit-frame-pointer` and `/Oy` allow this use. Options `-fno-omit-frame-pointer` and `/Oy-` disallow it.

Some debuggers expect EBP to be used as a stack frame pointer, and cannot produce a stack backtrace unless this is so. The `-fno-omit-frame-pointer` and `/Oy-` options direct the compiler to generate code that maintains and uses EBP as a stack frame pointer for all functions so that a debugger can still produce a stack backtrace without doing the following:

- For `-fno-omit-frame-pointer`: turning off optimizations with `-O0`
- For `/Oy-`: turning off `/O1`, `/O2`, or `/O3` optimizations

The `-fno-omit-frame-pointer` option is set when you specify option `-O0` or the `-g` option. The `-fomit-frame-pointer` option is set when you specify option `-O1`, `-O2`, or `-O3`.

The `/Oy` option is set when you specify the `/O1`, `/O2`, or `/O3` option. Option `/Oy-` is set when you specify the `/Od` option.

Using the `-fno-omit-frame-pointer` or `/Oy-` option reduces the number of available general-purpose registers by 1, and can result in slightly less efficient code.

Alternate Options

Linux and Mac OS X: `-fp` (this is a deprecated option)

Windows: None

Fo

See object

fomit-frame-pointer, Oy

Determines whether EBP is used as a general-purpose register in optimizations.

IDE Equivalent

Windows: **Optimization > Omit Frame Pointers**

Linux: None

Mac OS X: **Optimization > Provide Frame Pointer**

Architectures

`-f[no-]omit-frame-pointer`: IA-32 architecture, Intel® 64 architecture

`/Oy[-]`: IA-32 architecture

Syntax

Linux and Mac OS X:

```
-fomit-frame-pointer
-fno-omit-frame-pointer
```

Windows:

```
/Oy
/Oy-
```

Arguments

None

Default

`-fomit-frame-pointer` or `/Oy`	EBP is used as a general-purpose register in optimizations. However, on Linux* and Mac OS X systems, the default is `-fno-omit-frame-pointer` if option `-O0` or `-g` is specified. On Windows* systems, the default is `/Oy-` if option `/Od` is specified.

Description

These options determine whether EBP is used as a general-purpose register in optimizations. Options `-fomit-frame-pointer` and `/Oy` allow this use. Options `-fno-omit-frame-pointer` and `/Oy-` disallow it.

Some debuggers expect EBP to be used as a stack frame pointer, and cannot produce a stack backtrace unless this is so. The `-fno-omit-frame-pointer` and `/Oy-` options direct the compiler to generate code that maintains and uses EBP as a stack frame pointer for all functions so that a debugger can still produce a stack backtrace without doing the following:

- For `-fno-omit-frame-pointer`: turning off optimizations with `-O0`
- For `/Oy-`: turning off `/O1`, `/O2`, or `/O3` optimizations

The `-fno-omit-frame-pointer` option is set when you specify option `-O0` or the `-g` option. The `-fomit-frame-pointer` option is set when you specify option `-O1`, `-O2`, or `-O3`.

The `/Oy` option is set when you specify the `/O1`, `/O2`, or `/O3` option. Option `/Oy-` is set when you specify the `/Od` option.

Using the `-fno-omit-frame-pointer` or `/Oy-` option reduces the number of available general-purpose registers by 1, and can result in slightly less efficient code.

Alternate Options

Linux and Mac OS X: `-fp` (this is a deprecated option)

Windows: None

fp-model, fp

Controls the semantics of floating-point calculations.

IDE Equivalent

Windows: Floating Point > Floating Point Model

Floating Point > Reliable Floating Point Exceptions Model

Linux: None

Mac OS X: **Floating Point > Floating Point Model**

Floating Point > Reliable Floating Point Exceptions Model

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fp-model` *keyword*

Windows:

`/fp:`*keyword*

Arguments

keyword Specifies the semantics to be used. Possible values are:

`precise`	Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision.
`fast[=1|2]`	Enables more aggressive optimizations on floating-point data.
`strict`	Enables precise and except, disables contractions, and enables the property that allows modification of the floating-point environment.
`source`	Rounds intermediate results to source-defined precision and enables value-safe optimizations.
`[no-]except` (Linux and Mac OS X) or `except[-]` (Windows)	Determines whether floating-point exception semantics are used.

Default

`-fp-model fast=1` or `/fp:fast=1`	The compiler uses more aggressive optimizations on floating-point calculations.

Description

This option controls the semantics of floating-point calculations.

The *keywords* can be considered in groups:

- Group A: `precise`, `fast`, `strict`
- Group B: `source`
- Group C: `except` (or the negative form)

You can use more than one *keyword*. However, the following rules apply:

- You cannot specify `fast` and `except` together in the same compilation. You can specify any other combination of group A, group B, and group C.
  Since `fast` is the default, you must not specify `except` without a group A or group B *keyword*.
- You should specify only one *keyword* from group A and only one keyword from group B. If you try to specify more than one *keyword* from either group A or group B, the last (rightmost) one takes effect.
- If you specify `except` more than once, the last (rightmost) one takes effect.

Option	Description
`-fp-model precise` or `/fp:precise`	Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations. It disables optimizations that can change the result of floating-point calculations. These semantics ensure the accuracy of floating-point computations, but they may slow performance. The compiler assumes the default floating-point environment; you are not allowed to modify it.

Option	Description
	Floating-point exception semantics are disabled by default. To enable these semantics, you must also specify `-fp-model except` or `/fp:except`. For information on the semantics used to interpret floating-point calculations in the source code, see `precise` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.
`-fp-model fast[=1|2]` or `/fp:fast[=1|2]`	Tells the compiler to use more aggressive optimizations when implementing floating-point calculations. These optimizations increase speed, but may alter the accuracy of floating-point computations. Specifying fast is the same as specifying `fast=1`. `fast=2` may produce faster and less accurate results. Floating-point exception semantics are disabled by default and they cannot be enabled because you cannot specify fast and except together in the same compilation. To enable exception semantics, you must explicitly specify another keyword (see other keyword descriptions for details). For information on the semantics used to interpret floating-point calculations in the source code, see `fast` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.
`-fp-model strict` or `/fp:strict`	Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations and enables floating-point exception semantics. This is the strictest floating-point model.

Option	Description
	The compiler does not assume the default floating-point environment; you are allowed to modify it. Floating-point exception semantics can be disabled by explicitly specifying `-fp-model no-except` or `/fp:except-`. For information on the semantics used to interpret floating-point calculations in the source code, see `strict` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.
`-fp-model source` or `/fp:source`	This option causes intermediate results to be rounded to the precision defined in the source code. It also implies keyword `precise` unless it is overridden by a keyword from Group A. The compiler assumes the default floating-point environment; you are not allowed to modify it. For information on the semantics used to interpret floating-point calculations in the source code, see `source` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.

NOTE. This option cannot be used to change the default (source) precision for the calculation of intermediate results.

NOTE. On Windows and Linux operating systems on IA-32 architecture, the compiler, by default, implements floating-point (FP) arithmetic using SSE2 and SSE instructions. This can cause differences in floating-point results when compared to previous x87 implementations.

Alternate Options

None

Example

For examples of how to use this option, see *Floating-point Operations: Using the* `-fp-model (/fp)` *Option*.

fp-model, fp

Controls the semantics of floating-point calculations.

IDE Equivalent

Windows: Floating Point > Floating Point Model

Floating Point > Reliable Floating Point Exceptions Model

Linux: None

Mac OS X: **Floating Point > Floating Point Model**

Floating Point > Reliable Floating Point Exceptions Model

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fp-model` *keyword*

Windows:

`/fp:keyword`

Arguments

keyword	Specifies the semantics to be used. Possible values are:	
	`precise`	Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision.
	`fast[=1|2]`	Enables more aggressive optimizations on floating-point data.
	`strict`	Enables precise and except, disables contractions, and enables the property that allows modification of the floating-point environment.
	`source`	Rounds intermediate results to source-defined precision and enables value-safe optimizations.
	`[no-]except` (Linux and Mac OS X) or `except[-]` (Windows)	Determines whether floating-point exception semantics are used.

Default

`-fp-model fast=1` or `/fp:fast=1`	The compiler uses more aggressive optimizations on floating-point calculations.

Description

This option controls the semantics of floating-point calculations.

The *keywords* can be considered in groups:

- Group A: `precise`, `fast`, `strict`
- Group B: `source`
- Group C: `except` (or the negative form)

You can use more than one *keyword*. However, the following rules apply:

- You cannot specify `fast` and `except` together in the same compilation. You can specify any other combination of group A, group B, and group C.
  Since `fast` is the default, you must not specify `except` without a group A or group B *keyword*.
- You should specify only one *keyword* from group A and only one keyword from group B. If you try to specify more than one *keyword* from either group A or group B, the last (rightmost) one takes effect.
- If you specify `except` more than once, the last (rightmost) one takes effect.

Option	Description
`-fp-model precise` or `/fp:precise`	Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations. It disables optimizations that can change the result of floating-point calculations. These semantics ensure the accuracy of floating-point computations, but they may slow performance. The compiler assumes the default floating-point environment; you are not allowed to modify it. Floating-point exception semantics are disabled by default. To enable these semantics, you must also specify `-fp-model except` or `/fp:except`. For information on the semantics used to interpret floating-point calculations in the source code, see `precise` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.
`-fp-model fast[=1|2]` or `/fp:fast[=1|2]`	Tells the compiler to use more aggressive optimizations when implementing floating-point calculations. These optimizations increase speed, but may alter the accuracy of floating-point computations.

Option	Description
	Specifying fast is the same as specifying `fast=1`. `fast=2` may produce faster and less accurate results. Floating-point exception semantics are disabled by default and they cannot be enabled because you cannot specify fast and except together in the same compilation. To enable exception semantics, you must explicitly specify another keyword (see other keyword descriptions for details). For information on the semantics used to interpret floating-point calculations in the source code, see `fast` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.
`-fp-model strict` or `/fp:strict`	Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations and enables floating-point exception semantics. This is the strictest floating-point model. The compiler does not assume the default floating-point environment; you are allowed to modify it. Floating-point exception semantics can be disabled by explicitly specifying `-fp-model no-except` or `/fp:except-`. For information on the semantics used to interpret floating-point calculations in the source code, see `strict` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.

Option	Description
`-fp-model source` or `/fp:source`	This option causes intermediate results to be rounded to the precision defined in the source code. It also implies keyword `precise` unless it is overridden by a keyword from Group A. The compiler assumes the default floating-point environment; you are not allowed to modify it. For information on the semantics used to interpret floating-point calculations in the source code, see `source` in *Floating-point Operations: Using the* `-fp-model` *(*`/fp`*) Option*.

NOTE. This option cannot be used to change the default (source) precision for the calculation of intermediate results.

NOTE. On Windows and Linux operating systems on IA-32 architecture, the compiler, by default, implements floating-point (FP) arithmetic using SSE2 and SSE instructions. This can cause differences in floating-point results when compared to previous x87 implementations.

Alternate Options

None

The MSDN article Microsoft Visual C++ Floating-Point Optimization, which discusses concepts that apply to this option.

fp-port, Qfp-port

Rounds floating-point results after floating-point operations.

IDE Equivalent

Windows: **Floating-Point > Round Floating-Point Results**

Linux: None

Mac OS X: **Floating-Point > Round Floating-Point Results**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fp-port`

`-no-fp-port`

Windows:

`/Qfp-port`

`/Qfp-port-`

Arguments

None

Default

`-no-fp-port` or `/Qfp-port-`	The default rounding behavior depends on the compiler's code generation decisions and the precision parameters of the operating system.

Description

This option rounds floating-point results after floating-point operations. Rounding to user-specified precision occurs at assignments and type conversions. This has some impact on speed.

The default is to keep results of floating-point operations in higher precision. This provides better performance but less consistent floating-point results.

Alternate Options

None

fp-relaxed, Qfp-relaxed

Enables use of faster but slightly less accurate code sequences for math functions.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

```
-fp-relaxed
-no-fp-relaxed
```

Mac OS X:

```
None
```

Windows:

```
/Qfp-relaxed
/Qfp-relaxed-
```

Arguments

None

Default

`-no-fp-relaxed` or `/Qfp-relaxed-`	Default code sequences are used for math functions.

Description

This option enables use of faster but slightly less accurate code sequences for math functions, such as divide and sqrt. When compared to strict IEEE* precision, this option slightly reduces the accuracy of floating-point calculations performed by these functions, usually limited to the least significant digit.

This option also enables the performance of more aggressive floating-point transformations, which may affect accuracy.

Alternate Options

Linux: `-IPF-fp-relaxed` (this is a deprecated option)

Windows: `/QIPF-fp-relaxed` (this is a deprecated option)

- `fp-model, fp`

fp-speculation, Qfp-speculation

Tells the compiler the mode in which to speculate on floating-point operations.

IDE Equivalent

Windows: **Floating Point > Floating-Point Speculation**

Linux: None

Mac OS X: **Floating Point > Floating-Point Speculation**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fp-speculation=`*mode*

Windows:

`/Qfp-speculation:`*mode*

Arguments

mode	Is the mode for floating-point operations. Possible values are:
`fast`	Tells the compiler to speculate on floating-point operations.
`safe`	Tells the compiler to disable speculation if there is a possibility that the speculation may cause a floating-point exception.
`strict`	Tells the compiler to disable speculation on floating-point operations.
`off`	This is the same as specifying strict.

Default

`-fp-speculation=fast` or `/Qfp-speculation:fast`	The compiler speculates on floating-point operations. This is also the behavior when optimizations are enabled. However, if you specify no optimizations (`-O0` on Linux; `/Od` on Windows), the default is `-fp-speculation=safe` (Linux) or `/Qfp-speculation:safe` (Windows).

Description

This option tells the compiler the mode in which to speculate on floating-point operations.

Alternate Options

None

-

fp-stack-check, Qfp-stack-check

Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.

IDE Equivalent

Windows: **Floating-Point > Check Floating-point Stack**

Linux: None

Mac OS X: **Floating-Point > Check Floating-point Stack**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-fp-stack-check
```

Windows:

```
/Qfp-stack-check
```

Arguments

None

Default

OFF	There is no checking to ensure that the floating-point (FP) stack is in the expected state.

Description

This option tells the compiler to generate extra code after every function call to ensure that the floating-point (FP) stack is in the expected state.

By default, there is no checking. So when the FP stack overflows, a NaN value is put into FP calculations and the program's results differ. Unfortunately, the overflow point can be far away from the point of the actual bug. This option places code that causes an access violation exception immediately after an incorrect call occurs, thus making it easier to locate these issues.

Alternate Options

None

•
•

Floating-point Operations:

- Checking the Floating-point Stack State

fpconstant

Tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.

IDE Equivalent

Windows: **Floating-Point > Extend Precision of Single-Precision Constants**

Linux: None

Mac OS X: **Floating-Point > Extend Precision of Single-Precision Constants**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fpconstant`

`-nofpconstant`

Windows:

`/fpconstant`

`/nofpconstant`

Arguments

None

Default

`nofpconstant`	Single-precision constants assigned to double-precision variables are evaluated in single precision according to Fortran 95/90 Standard rules.

Description

This option tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.

This is extended precision. It does not comply with the Fortran 95/90 standard, which requires that single-precision constants assigned to double-precision variables be evaluated in single precision.

It allows compatibility with FORTRAN 77, where such extended precision was allowed. If this option is not used, certain programs originally created for FORTRAN 77 compilers may show different floating-point results because they rely on the extended precision for single-precision constants assigned to double-precision variables.

Alternate Options

None

Example

In the following example, if you specify `fpconstant`, identical values are assigned to D1 and D2. If you omit `fpconstant`, the compiler will obey the Fortran 95/90 Standard and assign a less precise value to D1:

```
REAL (KIND=8) D1, D2
DATA D1 /2.71828182846182/ ! REAL (KIND=4) value expanded to double
DATA D2 /2.71828182846182D0/ ! Double value assigned to double
```

fpe

Allows some control over floating-point exception handling for the main program at run-time.

IDE Equivalent

Windows: **Floating-Point > Floating-Point Exception Handling**

Linux: None

Mac OS X: **Floating-Point > Floating-Point Exception Handling**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fpe`*n*

Windows:

`/fpe:`*n*

Arguments

n	Specifies the floating-point exception handling level. Possible values are:
`0`	Floating-point invalid, divide-by-zero, and overflow exceptions are enabled. If any such exceptions occur, execution is aborted. This option sets the `-ftz` (Linux and Mac OS X) or `/Qftz` (Windows) option; therefore underflow results will be set to zero unless you explicitly specify `-no-ftz` (Linux and Mac OS X) or `/Qftz-` (Windows). On systems using IA-64 architecture, underflow behavior is equivalent to specifying option `-ftz` or `/Qftz`. On systems using IA-32 architecture or Intel® 64 architecture, underflow results from SSE instructions, as well as x87 instructions, will be set to zero. By contrast, option `-ftz` or `/Qftz` only sets SSE underflow results to zero. To get more detailed location information about where the error occurred, use option `traceback`.

`1`	All floating-point exceptions are disabled. On systems using IA-64 architecture, underflow behavior is equivalent to specifying option `-ftz` or `/Qftz`. On systems using IA-32 architecture or Intel® 64 architecture, underflow results from SSE instructions, as well as x87 instructions, will be set to zero.
`3`	All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero, such as `-ftz` or `/Qftz`, `O3`, or `O2` on systems using IA-32 architecture or Intel® 64 architecture. This setting provides full IEEE support.

Default

`-fpe3` or `/fpe:3`	All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero.

Description

This option allows some control over floating-point exception handling for the main program at run-time. This includes whether exceptional floating-point values are allowed and how precisely run-time exceptions are reported.

The `fpe` option affects how the following conditions are handled:

- When floating-point calculations result in a divide by zero, overflow, or invalid operation.
- When floating-point calculations result in an underflow.
- When a denormalized number or other exceptional number (positive infinity, negative infinity, or a NaN) is present in an arithmetic expression.

When enabled exceptions occur, execution is aborted and the cause of the abort reported to the user. If compiler option `traceback` is specified at compile time, detailed information about the location of the abort is also reported.

This option does not enable underflow exceptions, input denormal exceptions, or inexact exceptions.

Alternate Options

None

See Also

-
- `fpe-all`
- `ftz`, `Qftz`
- `traceback`
- Using the -fpe or /fpe Compiler Option

fpe-all

Allows some control over floating-point exception handling for each routine in a program at run-time.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fpe-all=`*n*

Windows:

`/fpe-all:`*n*

Arguments

n	Specifies the floating-point exception handling level. Possible values are:
`0`	Floating-point invalid, divide-by-zero, and overflow exceptions are enabled. If any such exceptions occur, execution is

	aborted. This option sets the `-ftz` (Linux and Mac OS X) or `/Qftz` (Windows) option; therefore underflow results will be set to zero unless you explicitly specify `-no-ftz` (Linux and Mac OS X) or `/Qftz-` (Windows). On systems using IA-64 architecture, underflow behavior is equivalent to specifying option `-ftz` or `/Qftz`. On systems using IA-32 architecture or Intel® 64 architecture, underflow results from SSE instructions, as well as x87 instructions, will be set to zero. By contrast, option `-ftz` or `/Qftz` only sets SSE underflow results to zero. To get more detailed location information about where the error occurred, use option `traceback`.
`1`	All floating-point exceptions are disabled. On systems using IA-64 architecture, underflow behavior is equivalent to specifying option `-ftz` or `/Qftz`. On systems using IA-32 architecture or Intel® 64 architecture, underflow results from SSE instructions, as well as x87 instructions, will be set to zero.
`3`	All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero, such as `-ftz` or `/Qftz`, `O3`, or `O2` on systems using IA-32 architecture or Intel® 64 architecture. This setting provides full IEEE support.

Default

`-fpe-all=3` or `/fpe-all:3` or the setting of `fpe` that the main program was compiled with	All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero.

Description

This option allows some control over floating-point exception handling for each routine in a program at run-time. This includes whether exceptional floating-point values are allowed and how precisely run-time exceptions are reported.

The `fpe-all` option affects how the following conditions are handled:

- When floating-point calculations result in a divide by zero, overflow, or invalid operation.
- When floating-point calculations result in an underflow.
- When a denormalized number or other exceptional number (positive infinity, negative infinity, or a NaN) is present in an arithmetic expression.

The current settings of the floating-point exception and status flags are saved on each routine entry and restored on each routine exit. This may incur some performance overhead.

When option `fpe-all` is applied to a main program, it has the same affect as when option `fpe` is applied to the main program.

When enabled exceptions occur, execution is aborted and the cause of the abort reported to the user. If compiler option `traceback` is specified at compile time, detailed information about the location of the abort is also reported.

This option does not enable underflow exceptions, input denormal exceptions, or inexact exceptions.

Option `fpe-all` sets option `assume ieee_fpe_flags`.

Alternate Options

None

-
- `assume`
- `fpe`

- ftz, Qftz
- traceback
- Using the -fpe or /fpe Compiler Option

fpic

Determines whether the compiler generates position-independent code.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fpic`

`-fno-pic`

Windows:

`None`

Arguments

None

Default

`-fno-pic` or `-fpic`	On systems using IA-32 or Intel® 64 architecture, the compiler does not generate position-independent code. On systems using IA-64 architecture, the compiler generates position-independent code.

Description

This option determines whether the compiler generates position-independent code.

Option `-fpic` specifies full symbol preemption. Global symbol definitions as well as global symbol references get default (that is, preemptable) visibility unless explicitly specified otherwise.

Option `-fno-pic` is only valid on systems using IA-32 or Intel® 64 architecture.

On systems using IA-32 or Intel® 64 architecture, `-fpic` must be used when building shared objects.

This option can also be specified as `-fPIC`.

Alternate Options

None

fpie

Tells the compiler to generate position-independent code. The generated code can only be linked into executables.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-fpie`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

OFF	The compiler does not generate position-independent code for an executable-only object.

Description

This option tells the compiler to generate position-independent code. It is similar to `-fpic`, but code generated by `-fpie` can only be linked into an executable.

Because the object is linked into an executable, this option causes better optimization of some symbol references.

To ensure that run-time libraries are set up properly for the executable, you should also specify option `-pie` to the compiler driver on the link command line.

Option `-fpie` can also be specified as `-fPIE`.

Alternate Options

None

-
- fpic
- pie

fpp, Qfpp

Runs the Fortran preprocessor on source files before compilation.

IDE Equivalent

Windows: **Preprocessor > Preprocess Source File**

Linux: None

Mac OS X: Preprocessor > Preprocess Source File

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`fpp[`*`n`*`]`

`fpp[="`*`option`*`"]`

`-nofpp`

Windows:

`/fpp[n]`

`/fpp[:"option"]`

`/nofpp`

`/Qfpp[n]`

`/Qfpp[:"option"]`

Arguments

n	Deprecated. Tells the compiler whether to run the preprocessor or not. Possible values are:
	`0` Tells the compiler not to run the preprocessor.
	`1, 2, or 3` Tells the compiler to run the preprocessor.
option	Is a Fortran preprocessor (fpp) option; for example, "-macro=no", which disables macro expansion. The quotes are required. For a list of fpp options, see *Fortran Preprocessor Options*.

Default

`nofpp`	The Fortran preprocessor is not run on files before compilation.

Description

This option runs the Fortran preprocessor on source files before they are compiled.

If the option is specified with no argument, the compiler runs the preprocessor.

If `0` is specified for *n*, it is equivalent to `nofpp`.Note that argument *n* is deprecated.

We recommend you use option `Qoption,fpp,"option"` to pass fpp options to the Fortran preprocessor.

Alternate Options

Linux and Mac OS X: `-cpp`

Windows: `/Qcpp`

See Also

- Qoption

fpscomp

Controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel® Fortran or Microsoft Fortran PowerStation.*

IDE Equivalent

Windows: **Compatibility > Use Filenames from Command Line** (`/fpscomp:[no]filesfromcmd`)

Compatibility > Use PowerStation I/O Format (`/fpscomp:[no]ioformat`)

Compatibility > Use PowerStation Portability Library (`/fpscomp:[no]libs`)

Compatibility > Use PowerStation List-Directed I/O Spacing (`/fpscomp:[no]ldio_spacing`)

Compatibility > Use PowerStation Logical Values (`/fpscomp:[no]logicals`)

Compatibility > Use Other PowerStation Run-Time Behavior (`/fpscomp:[no]general`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fpscomp [keyword]`

`-nofpscomp`

Windows:

`/fpscomp[:keyword]`

/nofpscomp

Arguments

keyword Specifies the compatibility that the compiler should follow. Possible values are:

none	Specifies that no options should be used for compatibility.
[no]filesfromcmd	Determines what compatibility is used when the OPEN statement FILE= specifier is blank.
[no]general	Determines what compatibility is used when semantics differences exist between Fortran PowerStation and Intel® Fortran.
[no]ioformat	Determines what compatibility is used for list-directed formatted and unformatted I/O.
[no]libs	Determines whether the portability library is passed to the linker.
[no]ldio_spacing	Determines whether a blank is inserted at run-time after a numeric value before a character value.
[no]logicals	Determines what compatibility is used for representation of LOGICAL values.
all	Specifies that all options should be used for compatibility.

Default

fpscomp libs The portability library is passed to the linker.

Description

This option controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel Fortran or Microsoft* Fortran PowerStation.

If you experience problems when porting applications from Fortran PowerStation, specify fpscomp (or fpscomp all). When porting applications from Intel Fortran, use fpscomp none or fpscomp libs (the default).

Option	Description
`fpscomp none`	Specifies that no options should be used for compatibility with Fortran PowerStation. This is the same as specifying `nofpscomp`.Option `fpscomp none` enables full Intel® Fortran compatibility. If you omit `fpscomp`, the default is `fpscomp libs`. You cannot use the `fpscomp` and `vms` options in the same command.
`fpscomp filesfromcmd`	Specifies Fortran PowerStation behavior when the OPEN statement FILE= specifier is blank (FILE=' '). It causes the following actions to be taken at run-time: • The program reads a filename from the list of arguments (if any) in the command line that invoked the program. If any of the command-line arguments contain a null string (''), the program asks the user for the corresponding filename. Each additional OPEN statement with a blank FILE= specifier reads the next command-line argument. • If there are more nameless OPEN statements than command-line arguments, the program prompts for additional file names. • In a QuickWin application, a **File Select** dialog box appears to request file names. To prevent the run-time system from using the filename specified on the command line when the OPEN statement FILE specifier is omitted, specify `fpscomp nofilesfromcmd`. This allows the application of Intel Fortran defaults, such as the FORTn environment variable and the FORT.*n* file name (where *n* is the unit number). The `fpscomp filesfromcmd` option affects the following Fortran features: • The OPEN statement FILE specifier For example, assume a program OPENTEST contains the following statements: OPEN(UNIT = 2, FILE = ' ') OPEN(UNIT = 3, FILE = ' ') OPEN(UNIT = 4, FILE = ' ')

Option	Description
	The following command line assigns the file TEST.DAT to unit 2, prompts the user for a filename to associate with unit 3, then prompts again for a filename to associate with unit 4: opentest test.dat '' '' • Implicit file open statements such as the WRITE, READ, and ENDFILE statements Unopened files referred to in READ or WRITE statements are opened implicitly as if there had been an OPEN statement with a name specified as all blanks. The name is read from the command line.

`fpscomp general`	Specifies that Fortran PowerStation semantics should be used when a difference exists between Intel Fortran and Fortran PowerStation. The `fpscomp general` option affects the following Fortran features:
	
	• The BACKSPACE statement:
	
	  • It allows files opened with ACCESS='APPEND' to be used with the BACKSPACE statement.
	
	  • It allows files opened with ACCESS='DIRECT' to be used with the BACKSPACE statement.
	
	  Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be used with the BACKSPACE statement violates the Fortran 95 standard and may be removed in the future.
	
	• The READ statement:
	
	• • It causes a READ from a formatted file opened for direct access to read records that have the same record type format as Fortran PowerStation. This consists of accounting for the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record. It allows sequential reads from a formatted file opened for direct access.
	
	  Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be used with the sequential READ statement violates the Fortran 95 standard and may be removed in the future.

Option	Description
	• It allows the last record in a file opened with FORM='FORMATTED' and a record type of STREAM_LF or STREAM_CR that does not end with a proper record terminator (<line feed> or <carriage return>) to be read without producing an error. • It allows sequential reads from an unformatted file opened for direct access. • Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be read with the sequential READ statement violates the Fortran 95 standard and may be removed in the future. • The INQUIRE statement: • • The CARRIAGECONTROL specifier returns the value "UNDEFINED" instead of "UNKNOWN" when the carriage control is not known. • The NAME specifier returns the file name "UNKNOWN" instead of filling the file name with spaces when the file name is not known. • The SEQUENTIAL specifier returns the value "YES" instead of "NO" for a direct access formatted file. • The UNFORMATTED specifier returns the value "NO" instead of "UNKNOWN" when it is not known whether unformatted I/O can be performed to the file. Note: Returning the value "NO" instead of "UNKNOWN" for this specifier violates the Fortran 95 standard and may be removed in the future. • The OPEN statement: • • If a file is opened with an unspecified STATUS keyword value, and is not named (no FILE specifier), the file is opened as a scratch file. For example: OPEN (UNIT = 4) • In contrast, when fpscomp nogeneral is in effect with an unspecified STATUS value with no FILE specifier, the FORTn environment variable and the FORT.n file name are used (where n is the unit number).

Option	Description
	• If the STATUS value was not specified and if the name of the file is "USER", the file is marked for deletion when it is closed. • It allows a file to be opened with the APPEND and READONLY characteristics. • If the default for the CARRIAGECONTROL specifier is assumed, it gives "LIST" carriage control to direct access formatted files instead of "NONE". • If the default for the CARRIAGECONTROL specifier is assumed and the device type is a terminal file, the file is given the default carriage control value of "FORTRAN" instead of "LIST". • It gives an opened file the additional default of write sharing. • It gives the file a default block size of 1024 instead of 8192. • If the default for the MODE and ACTION specifier is assumed and there was an error opening the file, try opening the file as read only, then write only. • If a file that is being re-opened has a different file type than the current existing file, an error is returned. • It gives direct access formatted files the same record type as Fortran PowerStation. This means accounting for the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record. • The STOP statement: It writes the Fortran PowerStation output string and/or returns the same exit condition values. • The WRITE statement: • • Writing to formatted direct files When writing to a formatted file opened for direct access, records are written in the same record type format as Fortran PowerStation. This consists of adding the trailing Carriage Return/Line Feed pair <CR><LF>) that is part of the record. It ignores the CARRIAGECONTROL specifier setting when writing to a formatted direct access file. • Interpreting Fortran carriage control characters

Option	Description
	When interpreting Fortran carriage control characters during formatted I/O, carriage control sequences are written that are the same as Fortran PowerStation. This is true for the "Space, 0, 1 and + " characters. • Performing non-advancing I/O to the terminal When performing non-advancing I/O to the terminal, output is written in the same format as Fortran PowerStation. • Interpreting the backslash (\) and dollar ($) edit descriptors When interpreting backslash and dollar edit descriptors during formatted I/O, sequences are written the same as Fortran PowerStation. • Performing sequential writes It allows sequential writes from an unformatted file opened for direct access. Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be read with the sequential WRITE statement violates the Fortran 95 standard and may be removed in the future. Specifying `fpscomp general` sets `fpscomp ldio_spacing`.
`fpscomp ioformat`	Specifies that Fortran PowerStation semantic conventions and record formats should be used for list-directed formatted and unformatted I/O. The fpscomp ioformat option affects the following Fortran features: • The WRITE statement: • • For formatted list-directed WRITE statements, formatted internal list-directed WRITE statements, and formatted namelist WRITE statements, the output line, field width values, and the list-directed data type semantics are determined according to the following sample for real constants (N below): For 1 <= N < 10**7, use F15.6 for single precision or F24.15 for double.

Option	Description

For N < 1 or N >= 10**7, use E15.6E2 for single precision or E24.15E3 for double.

See the Fortran PowerStation documentation for more detailed information about the other data types affected.

- For unformatted WRITE statements, the unformatted file semantics are dictated according to the Fortran PowerStation documentation; these semantics are different from the Intel Fortran file format. See the Fortran PowerStation documentation for more detailed information.

The following table summarizes the default output formats for list-directed output with the intrinsic data types:

Data Type	Output Format with fpscomp noioformat	Output Format with fpscomp ioformat
BYTE	I5	I12
LOGICAL (all)	L2	L2
INTEGER(1)	I5	I12
INTEGER(2)	I7	I12
INTEGER(4)	I12	I12
INTEGER(8)	I22	I22
REAL(4)	1PG15.7E2	1PG16.6E2
REAL(8)	1PG24.15E3	1PG25.15E3
COMPLEX(4)	'(',1PG14.7E2, ', ',1PG14.7E2, ') '	'(',1PG16.6E2, ', ',1PG16.6E2, ') '
COMPLEX(8)	'(',1PG23.15E3, ', ',1PG23.15E3, ') '	'(',1PG25.15E3, ', ',1PG25.15E3, ') '

Option	Description

Data Type	Output Format with fpscomp noioformat	Output Format with fpscomp ioformat
CHARACTER	Aw	Aw

- The READ statement:
- For formatted list-directed READ statements, formatted internal list-directed READ statements, and formatted namelist READ statements, the field width values and the list-directed semantics are dictated according to the following sample for real constants (N below):

  For 1 <= N < 10**7, use F15.6 for single precision or F24.15 for double.

  For N < 1 or N >= 10**7, use E15.6E2 for single precision or E24.15E3 for double.

  See the Fortran PowerStation documentation for more detailed information about the other data types affected.
- For unformatted READ statements, the unformatted file semantics are dictated according to the Fortran PowerStation documentation; these semantics are different from the Intel Fortran file format. See the Fortran PowerStation documentation for more detailed information.

`fpscomp nolibs` — Prevents the portability library from being passed to the linker.

`fpscomp ldio_spacing` — Specifies that at run time a blank should not be inserted after a numeric value before a character value (undelimited character string). This representation is used by Intel Fortran releases before Version 8.0 and by Fortran PowerStation. If you specify `fpscomp general`, it sets `fpscomp ldio_spacing`.

`fpscomp logicals` — Specifies that integers with a non-zero value are treated as true, integers with a zero value are treated as false. The literal constant .TRUE. has an integer value of 1, and the literal constant .FALSE. has an integer value of 0. This representation is used by Intel Fortran releases before Version

Option	Description
	8.0 and by Fortran PowerStation. The default is `fpscomp nologicals`, which specifies that odd integer values (low bit one) are treated as true and even integer values (low bit zero) are treated as false. The literal constant .TRUE. has an integer value of -1, and the literal constant .FALSE. has an integer value of 0. This representation is used by Compaq* Visual Fortran. The internal representation of LOGICAL values is not specified by the Fortran standard. Programs which use integer values in LOGICAL contexts, or which pass LOGICAL values to procedures written in other languages, are non-portable and may not execute correctly. Intel recommends that you avoid coding practices that depend on the internal representation of LOGICAL values. The `fpscomp logical` option affects the results of all logical expressions and affects the return value for the following Fortran features: • The INQUIRE statement specifiers OPENED, IOFOCUS, EXISTS, and NAMED • The EOF intrinsic function • The BTEST intrinsic function • The lexical intrinsic functions LLT, LLE, LGT, and LGE
`fpscomp all`	Specifies that all options should be used for compatibility with Fortran PowerStation. This is the same as specifying `fpscomp` with no keyword. Option `fpscomp all` enables full compatibility with Fortran PowerStation.

•

Building Applications: Microsoft Fortran PowerStation Compatible Files

FR

See free.

fr32

Disables the use of the high floating-point registers.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-fr32`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

OFF	The use of the high floating-point registers is enabled.

Description

This option disables the use of the high floating-point registers. Only the lower 32 floating-point registers are used.

Alternate Options

None

free

Specifies source files are in free format.

IDE Equivalent

Windows: **Language > Source File Format** (`/free`, `/fixed`)

Linux: None

Mac OS X: **Language > Source File Format** (`/free`, `/fixed`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-free`

`-nofree`

Windows:

`/free`

`/nofree`

Arguments

None

Default

OFF	The source file format is determined from the file extension.

Description

This option specifies source files are in free format. If this option is not specified, format is determined as follows:

- Files with an extension of .f90, .F90, or .i90 are free-format source files.
- Files with an extension of .f, .for, .FOR, .ftn, or .i are fixed-format files.

Alternate Options

Linux and Mac OS X: `-FR`

Windows: `/nofixed`, `/FR`, `/4Yf`

See Also

-
- `fixed`

fsource-asm

Produces an assembly listing with source code annotations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fsource-asm`

Windows:

`None`

Arguments

None

Default

OFF	No source code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with source code annotations. The assembly listing file shows the source code as interspersed comments.

To use this option, you must also specify option `-S`, which causes an assembly listing to be generated.

Alternate Options

Linux and Mac OS X: None

Windows: `/asmattr:source`, `/FAs`

See Also

-
- `S`

fstack-security-check, GS

Determines whether the compiler generates code that detects some buffer overruns.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-fstack-security-check`

`-fno-stack-security-check`

Windows:

`/GS`

`/GS-`

Arguments

None

Default

`-fno-stack-security-check`	The compiler does not detect buffer overruns.

or /GS-

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite the return address. This is a common technique for exploiting code that does not enforce buffer size restrictions.

The /GS option is supported with Microsoft Visual Studio .NET 2003* and Microsoft Visual Studio 2005*.

Alternate Options

Linux and Mac OS X: -f[no-]stack-protector

Windows: None

fstack-security-check, GS

Determines whether the compiler generates code that detects some buffer overruns.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

-fstack-security-check

-fno-stack-security-check

Windows:

/GS

/GS-

Arguments

None

Default

`-fno-stack-security-check` or `/GS-`	The compiler does not detect buffer overruns.

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite the return address. This is a common technique for exploiting code that does not enforce buffer size restrictions.

The `/GS` option is supported with Microsoft Visual Studio .NET 2003* and Microsoft Visual Studio 2005*.

Alternate Options

Linux and Mac OS X: `-f[no-]stack-protector`

Windows: None

fsyntax-only

See syntax-only.

ftrapuv, Qtrapuv

Initializes stack local variables to an unusual value to aid error detection.

IDE Equivalent

Windows: **Data > Initialize stack variables to an unusual value**

Linux: None

Mac OS X: **Run-Time > Initialize Stack Variables to an Unusual Value**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ftrapuv`

Windows:

`/Qtrapuv`

Arguments

None

Default

OFF	The compiler does not initialize local variables.

Description

This option initializes stack local variables to an unusual value to aid error detection. Normally, these local variables should be initialized in the application.

The option sets any uninitialized local variables that are allocated on the stack to a value that is typically interpreted as a very large integer or an invalid address. References to these variables are then likely to cause run-time errors that can help you detect coding errors.

This option sets option `-g` (Linux and Mac OS X) and `/Zi` or `/Z7` (Windows).

Alternate Options

None

-
-
- `g`, `Zi`, `Z7`

ftz, Qftz

Flushes denormal results to zero.

IDE Equivalent

Windows: (IA-32 and IA-64 architectures): **Floating Point > Flush Denormal Results to Zero**

(Intel® 64 architecture): None

Linux: None

Mac OS X: **Floating Point > Flush Denormal Results to Zero**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ftz`

`-no-ftz`

Windows:

`/Qftz`

`/Qftz-`

Arguments

None

Default

Systems using IA-64 architecture: `-no-ftz` or `/Qftz-` Systems using IA-32 architecture and Intel® 64 architecture: `-ftz` or `/Qftz`	On systems using IA-64 architecture, the compiler lets results gradually underflow. On systems using IA-32 architecture and Intel® 64 architecture, denormal results are flushed to zero.

Description

This option flushes denormal results to zero when the application is in the gradual underflow mode. It may improve performance if the denormal values are not critical to your application's behavior.

This option sets or resets the FTZ and the DAZ hardware flags. If FTZ is ON, denormal results from floating-point calculations will be set to the value zero. If FTZ is OFF, denormal results remain as is. If DAZ is ON, denormal values used as input to floating-point instructions will be treated as zero. If DAZ is OFF, denormal instruction inputs remain as is. Systems using IA-64 architecture have FTZ but not DAZ. Systems using Intel® 64 architecture have both FTZ and DAZ. FTZ and DAZ are not supported on all IA-32 architectures.

When `-ftz` (Linux and Mac OS X) or `/Qftz` (Windows) is used in combination with an SSE-enabling option on systems using IA-32 architecture (for example, `xN` or `QxN`), the compiler will insert code in the main routine to set FTZ and DAZ. When `-ftz` or `/Qftz` is used without such an option, the compiler will insert code to conditionally set FTZ/DAZ based on a run-time processor check. `-no-ftz` (Linux and Mac OS X) or `/Qftz-` (Windows) will prevent the compiler from inserting any code that might set FTZ or DAZ.

This option only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in FTZ/DAZ mode.

Options `-fpe0` and `-fpe1` (Linux and Mac OS X) set `-ftz`. Options `/fpe:0` and `/fpe:1` (Windows) set `/Qftz`.

On systems using IA-64 architecture, optimization option `O3` sets `-ftz` and `/Qftz`; optimization option `O2` sets `-no-ftz` (Linux) and `/Qftz-` (Windows). On systems using IA-32 architecture and Intel® 64 architecture, every optimization option `O` level, except `O0`, sets `-ftz` and `/Qftz`.

If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by using `-no-ftz` or `/Qftz-` in the command line while still benefiting from the `O3` optimizations.

NOTE. Options `-ftz` and `/Qftz` are performance options. Setting these options does not guarantee that all denormals in a program are flushed to zero. They only cause denormals generated at run time to be flushed to zero.

Alternate Options

None

- `x, Qx`

Floating-point Operations: Using the -fpe or /fpe Compiler Option

func-groups

This is a deprecated option. See prof-func-groups.

funroll-loops

See unroll, Qunroll.

fverbose-asm

Produces an assembly listing with compiler comments, including options and version information.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fverbose-asm`

`-fno-verbose-asm`

Windows:

`None`

Arguments

None

Default

`-fno-verbose-asm`	No source code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with compiler comments, including options and version information.

To use this option, you must also specify `-S`, which sets `-fverbose-asm`.

If you do not want this default when you specify `-S`, specify `-fno-verbose-asm`.

Alternate Options

None

See Also

-
- `S`

fvisibility

Specifies the default visibility for global symbols or the visibility for symbols in a file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fvisibility=`*`keyword`*

`-fvisibility-`*`keyword=file`*

Windows:

`None`

Arguments

`keyword`	Specifies the visibility setting. Possible values are:	
	`default`	Sets visibility to default.
	`extern`	Sets visibility to extern.
	`hidden`	Sets visibility to hidden.
	`internal`	Sets visibility to internal.

`protected`	Sets visibility to protected.
file	Is the pathname of a file containing the list of symbols whose visibility you want to set. The symbols must be separated by whitespace (spaces, tabs, or newlines).

Default

-fvisibility=default	The compiler sets visibility of symbols to default.

Description

This option specifies the default visibility for global symbols (syntax `-fvisibility=`*keyword*) or the visibility for symbols in a file (syntax `-fvisibility-`*keyword*`=`*file*).

Visibility specified by `-fvisibility-`*keyword*`=`*file* overrides visibility specified by `-fvisibility=`*keyword* for symbols specified in a file.

Option	Description
`-fvisibility=default` `-fvisibility-default=`*file*	Sets visibility of symbols to default. This means other components can reference the symbol, and the symbol definition can be overridden (preempted) by a definition of the same name in another component.
`-fvisibility=extern` `-fvisibility-extern=`*file*	Sets visibility of symbols to extern. This means the symbol is treated as though it is defined in another component. It also means that the symbol can be overridden by a definition of the same name in another component.
`-fvisibility=hidden` `-fvisibility-hidden=`*file*	Sets visibility of symbols to hidden. This means that other components cannot directly reference the symbol. However, its address may be passed to other components indirectly.

Option	Description
`-fvisibility=internal` `-fvisibility-internal=`*`file`*	Sets visibility of symbols to internal. This means the symbol cannot be referenced outside its defining component, either directly or indirectly.
`-fvisibility=protected` `-fvisibility-protected=`*`file`*	CELL_TEXT

If an `-fvisibility` option is specified more than once on the command line, the last specification takes precedence over any others.

If a symbol appears in more than one visibility *`file`*, the setting with the least visibility takes precedence.

The following shows the precedence of the visibility settings (from greatest to least visibility):

- `extern`
- `default`
- `protected`
- `hidden`
- `internal`

Note that `extern` visibility only applies to functions. If a variable symbol is specified as `extern`, it is assumed to be `default`.

Alternate Options

None

Example

A file named `prot.txt` contains symbols a, b, c, d, and e. Consider the following:

```
-fvisibility-protected=prot.txt
```

This option sets `protected` visibility for all the symbols in the file. It has the same effect as specifying `fvisibility=protected` in the declaration for each of the symbols.

- Symbol Visibility Attribute Options (Linux* and Mac OS* X)

g, Zi, Z7

Tells the compiler to generate full debugging information in the object file.

IDE Equivalent

Windows: **General > Debug Information Format** (`/Z7, /Zd, /Zi`)

Linux: None

Mac OS X: **General > Generate Debug Information** (`-g`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-g`

Windows:

`/Zi`

`/Z7`

Arguments

None

Default

OFF	No debugging information is produced in the object file.

Description

This option tells the compiler to generate symbolic debugging information in the object file for use by debuggers.

The compiler does not support the generation of debugging information in assemblable files. If you specify this option, the resulting object file will contain debugging information, but the assemblable file will not.

This option turns off `O2` and makes `O0` (Linux and Mac OS X) or `Od` (Windows) the default unless `O2` (or another `O` option) is explicitly specified in the same command line.

On Linux systems using Intel® 64 architecture and Linux and Mac OS X systems using IA-32 architecture, specifying the `-g` or `-O0` option sets the `-fno-omit-frame-pointer` option.

For more information on `Zi` and `Z7`, see keyword `full` in debug (Windows*).

Alternate Options

Linux and Mac OS X: None

Windows: `/debug:full` (or `/debug`)

G2, G2-p9000

Optimizes application performance for systems using IA-64 architecture.

IDE Equivalent

Windows: **Optimization > Optimize For Intel® Processor**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux and Mac OS X:

`None`

Windows:

`/G2`

`/G2-p9000`

Arguments

None

Default

`/G2-p9000`	Performance is optimized for Dual-Core Intel® Itanium® 2 processor 9000 series.

Description

These options optimize application performance for a particular Intel® processor or family of processors. The compiler generates code that takes advantage of features of IA-64 architecture.

Option	Description
`G2`	Optimizes for Intel® Itanium® 2 processors.
`G2-p9000`	Optimizes for Dual-Core Intel® Itanium® 2 processor 9000 series. This option affects the order of the generated instructions, but the generated instructions are limited to Intel® Itanium® 2 processor instructions unless the program specifies and executes intrinsics specific to the Dual-Core Intel® Itanium® 2 processor 9000 series.

The resulting executable is backwards compatible and generated code is optimized for specific processors. For example, code generated with `/G2-p9000` will run correctly on single-core Itanium® 2 processors, but it might not run as fast as if it had been generated using `/G2`.

Alternate Options

`/G2`	Linux: `-mtune=itanium2` Mac OS X: None Windows: None

`/G2-p9000`	Linux: `-mtune=itanium2-p9000`, `-mcpu=itanium2-p9000` (-mcpu is a deprecated option) Mac OS X: None Windows: None

Example

In the following example, the compiled binary of the source program prog.f is optimized for the Dual-Core Intel® Itanium® 2 processor 9000 series by default. The same binary will also run on single-core Itanium® 2 processors (unless the program specifies and executes intrinsics specific to the Dual-Core Intel® Itanium® 2 processor 9000 series). All lines in the code example are equivalent.

```
ifort prog.f
```

```
ifort /G2-p9000 prog.f
```

In the following example, the compiled binary is optimized for single-core Itanium® 2 processors:

```
ifort /G2 prog.f
```

- `mtune`

G5, G6, G7

Optimize application performance for systems using IA-32 architecture and Intel® 64 architecture. These are deprecated options.

IDE Equivalent

Windows: **Optimization > Optimize For Intel(R) Processor** (`/GB`, `/G5`, `/G6`, `/G7`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/G5`

`/G6`

`/G7`

Arguments

None

Default

/G7	On systems using IA-32 architecture and Intel® 64 architecture, performance is optimized for Intel® Pentium® 4 processors, Intel® Xeon® processors, Intel® Pentium® M processors, and Intel® Pentium® 4 processors with Streaming SIMD Extensions 3 (SSE3) instruction support.

Description

These options optimize application performance for a particular Intel® processor or family of processors. The compiler generates code that takes advantage of features of the specified processor.

Option	Description
G5	Optimizes for Intel® Pentium® and Pentium® with MMX™ technology processors.
G6	Optimizes for Intel® Pentium® Pro, Pentium® II and Pentium® III processors.
G7	Optimizes for Intel® Core™ Duo processors, Intel® Core™ Solo processors, Intel® Pentium® 4 processors, Intel® Xeon® processors based on the Intel® Core microarchitecture, Intel® Pentium® M processors, and Intel® Pentium® 4 processors with Streaming SIMD Extensions 3 (SSE3) instruction support.

On systems using Intel® 64 architecture, only option G7 is valid.

These options always generate code that is backwards compatible with Intel processors of the same architecture. For example, code generated with the G7 option runs correctly on Pentium III processors, although performance may be faster on Pentium III processors when compiled using or G6.

Alternate Options

Windows: `/GB` (an alternate for `/G6`; this option is also deprecated)

Linux: None

Example

In the following example, the compiled binary of the source program prog.f is optimized, by default, for Intel® Pentium® 4 processors, Intel® Xeon® processors, Intel® Pentium® M processors, and Intel® Pentium® 4 processors with Streaming SIMD Extensions 3 (SSE3). The same binary will also run on Pentium, Pentium Pro, Pentium II, and Pentium III processors. All lines in the code example are equivalent.

```
ifort prog.f
```

```
ifort /G7 prog.f
```

In the following example, the compiled binary is optimized for Pentium processors and Pentium processors with MMX technology:

```
ifort /G5 prog.f
```

```
icl /G5 prog.c
```

-
- `mtune`

gdwarf-2

Enables generation of debug information using the DWARF2 format.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-gdwarf-2`

Windows:

`None`

Arguments

None

Default

OFF	No debug information is generated. However, if compiler option `-g` is specified, debug information is generated in the latest DWARF format, which is currently DWARF2.

Description

This option enables generation of debug information using the DWARF2 format. This is currently the default when compiler option `-g` is specified.

Alternate Options

None

See Also

-
- `g`

Ge

Enables stack-checking for all functions.
This option has been deprecated.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Ge`

Arguments

None

Default

OFF	Stack-checking for all functions is disabled.

Description

This option enables stack-checking for all functions.

Alternate Options

None

gen-interfaces

Tells the compiler to generate an interface block for each routine in a source file.

IDE Equivalent

Windows: **Diagnostics > Generate Interface Blocks**

Linux: None

Mac OS X: **Diagnostics > Generate Interface Blocks**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-gen-interfaces [[no]source]`

`-nogen-interfaces`

Windows:

`/gen-interfaces[:[no]source]`

`/nogen-interfaces`

Arguments

None

Default

`nogen-interfaces`	The compiler does not generate interface blocks for routines in a source file.

Description

This option tells the compiler to generate an interface block for each routine (that is, for each SUBROUTINE and FUNCTION statement) defined in the source file. The compiler generates two files for each routine, a .mod file and a .f90 file, and places them in the current directory or in the directory specified by the include (`-I`) or `-module` option. The .f90 file is the text of the interface block; the .mod file is the interface block compiled into binary form.

If `source` is specified, the compiler creates the *_mod.f90 as well as the *_mod.mod files. If `nosource` is specified, the compiler creates the *_mod.mod but not the *_mod.f90 files. If neither is specified, it is the same as specifying `-gen-interfaces source` (Linux and Mac OS X) or `/gen-interfaces:source` (Windows).

Alternate Options

None

global-hoist, Qglobal-hoist

Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-global-hoist`

`-no-global-hoist`

Windows:

`/Qglobal-hoist`

`/Qglobal-hoist-`

Arguments

None

Default

`-global-hoist` or `/Qglobal-hoist`	Certain optimizations are enabled that can move memory loads.

Description

This option enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source. In most cases, these optimizations are safe and can improve performance.

The `-no-global-hoist` (Linux and Mac OS X) or `/Qglobal-hoist-` (Windows) option is useful for some applications, such as those that use shared or dynamically mapped memory, which can fail if a load is moved too early in the execution stream (for example, before the memory is mapped).

Alternate Options

None

Gm

See keyword `cvf` *in iface.*

Gs

Disables stack-checking for routines with more than a specified number of bytes of local variables and compiler temporaries.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Gs[n]`

Arguments

n	Is the number of bytes of local variables and compiler temporaries.

Default

`4096`	Stack checking is disabled for routines with more than 4KB of stack space allocated.

Description

This option disables stack-checking for routines with *n* or more bytes of local variables and compiler temporaries. If you do not specify *n*, you get the default of 4096.

Alternate Options

None

fstack-security-check, GS

Determines whether the compiler generates code that detects some buffer overruns.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-fstack-security-check`

`-fno-stack-security-check`

Windows:

`/GS`

`/GS-`

Arguments

None

Default

`-fno-stack-security-check` or `/GS-`	The compiler does not detect buffer overruns.

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite the return address. This is a common technique for exploiting code that does not enforce buffer size restrictions.

The `/GS` option is supported with Microsoft Visual Studio .NET 2003* and Microsoft Visual Studio 2005*.

Alternate Options

Linux and Mac OS X: `-f[no-]stack-protector`

Windows: None

Gz

See keyword `stdcall` *in iface*

heap-arrays

Puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.

IDE Equivalent

Windows: **Optimization > Heap Arrays**

Linux: None

Mac OS X: **Optimization > Heap Arrays**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-heap-arrays [size]`

`-no-heap-arrays`

Windows:

`/heap-arrays[:size]`

`/heap-arrays-`

Arguments

size	Is an integer value representing the size of the arrays in kilobytes. Any arrays known at compile-time to be larger than *size* are allocated on the heap instead of the stack.

Default

`-no-heap-arrays` or `/heap-arrays-`	The compiler puts automatic arrays and arrays created for temporary computations in temporary storage in the stack storage area.

Description

This option puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.

If `heap-arrays` is specified and *size* is omitted, all automatic and temporary arrays are put on the heap. If 10 is specified for *size*, all automatic and temporary arrays larger than 10 KB are put on the heap.

Alternate Options

None

Example

In Fortran, an automatic array gets it size from a run-time expression. For example:

```
RECURSIVE SUBROUTINE F( N )
INTEGER :: N
REAL :: X ( N )     ! an automatic array
REAL :: Y ( 1000 )  ! an explicit-shape local array on the stack
```

Array X in the example above is affected by the `heap-array` option. Array Y is not.

help

Displays all available compiler options or a category of compiler options.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-help[`*category*`]`

Windows:

`/help[`*category*`]`

Arguments

category Is a category or class of options to display. Possible values are:

`advanced`	Displays advanced optimization options that allow fine tuning of compilation or allow control over advanced features of the compiler.
`codegen`	Displays Code Generation options.
`compatibility`	Displays options affecting language compatibility.
`component`	Displays options for component control.
`data`	Displays options related to interpretation of data in programs or the storage of data.
`deprecated`	Displays options that have been deprecated.
`diagnostics`	Displays options that affect diagnostic messages displayed by the compiler.
`float`	Displays options that affect floating-point operations.
`help`	Displays all the available help categories.
`inline`	Displays options that affect inlining.
`ipo`	Displays Interprocedural Optimization (IPO) options

`language`	Displays options affecting the behavior of the compiler language features.
`link`	Displays linking or linker options.
`misc`	Displays miscellaneous options that do not fit within other categories.
`openmp`	Displays OpenMP and parallel processing options.
`opt`	Displays options that help you optimize code.
`output`	Displays options that provide control over compiler output.
`pgo`	Displays Profile Guided Optimization (PGO) options.
`preproc`	Displays options that affect preprocessing operations.
`reports`	Displays options for optimization reports.

Default

OFF	No list is displayed unless this compiler option is specified.

Description

This option displays all available compiler options or a category of compiler options. If category is not specified, all available compiler options are displayed.

Alternate Options

Linux and Mac OS X: None

Windows: `/?`

homeparams

Tells the compiler to store parameters passed in registers to the stack.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux and Mac OS X:

`None`

Windows:

`/homeparams`

Arguments

None

Default

OFF	Register parameters are not written to the stack.

Description

This option tells the compiler to store parameters passed in registers to the stack.

Alternate Options

None

hotpatch

Tells the compiler to prepare a routine for hotpatching.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/hotpatch[:n]`

Arguments

n	An integer specifying the number of bytes the compiler should add before the function entry point.

Default

OFF	The compiler does not prepare routines for hotpatching.

Description

This option tells the compiler to prepare a routine for hotpatching. The compiler inserts nop padding around function entry points so that the resulting image is hot patchable.

Specifically, the compiler adds nop bytes after each function entry point and enough nop bytes before the function entry point to fit a direct jump instruction on the target architecture.

If *n* is specified, it overrides the default number of bytes that the compiler adds before the function entry point.

Alternate Options

None

I

Specifies an additional directory for the include path.

IDE Equivalent

Windows: **General > Additional Include Directories** (/include)

Preprocessor > Additional Include Directories (/include)

Linux: None

Mac OS X: Preprocessor > Additional Include Directories (/include)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-I`*dir*

Windows:

`/I`*dir*

Arguments

dir	Is the directory to add to the include path.

Default

OFF	The default include path is used.

Description

This option specifies an additional directory for the include path, which is searched for module files referenced in USE statements and include files referenced in INCLUDE statements. To specify multiple directories on the command line, repeat the option for each directory you want to add.

For all USE statements and for those INCLUDE statements whose file name does not begin with a device or directory name, the directories are searched in this order:

1. The directory containing the first source file.

   Note that if `assume nosource_include` is specified, this directory will not be searched.
2. The current working directory where the compilation is taking place (if different from the above directory).
3. Any directory or directories specified using the I option. If multiple directories are specified, they are searched in the order specified on the command line, from left to right.
4. On Linux and Mac OS X systems, any directories indicated using environment variable FPATH. On Windows systems, any directories indicated using environment variable INCLUDE.

This option affects fpp preprocessor behavior and the USE statement.

Alternate Options

Linux and Mac OS X: None

Windows: `/include`

See Also

-
- `X`
- `assume`

i-dynamic

This is a deprecated option. See shared-intel.

i-static

This is a deprecated option. See static-intel.

i2, i4, i8

See integer-size.

idirafter

Adds a directory to the second include file search path.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-idirafter`*`dir`*

Windows:

`None`

Arguments

`dir`	Is the name of the directory to add.

Default

OFF	Include file search paths include certain default directories.

Description

This option adds a directory to the second include file search path (after `-I`).

Alternate Options

None

iface

Specifies the default calling convention and argument-passing convention for an application.

IDE Equivalent

Windows: **External Procedures > Calling Convention** (`/iface:{cref|stdref|std-call|cvf|default}`)

External Procedures > String Length Argument Passing (`/iface:[no]mixed_str_len_arg`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/iface:`*`keyword`*

Arguments

keyword	Specifies the calling convention or the argument-passing convention. Possible values are:

`default`	Tells the compiler to use the default calling conventions.
`cref`	Tells the compiler to use calling conventions C, REFERENCE.
`cvf`	Tells the compiler to use calling conventions compatible with Compaq Visual Fortran*.
`[no]mixed_str_len_arg`	Determines the argument-passing convention for hidden-length character arguments.
`stdcall`	Tells the compiler to use calling convention STDCALL.
`stdref`	Tells the compiler to use calling conventions STDCALL, REFERENCE.

Default

`/iface:default`	The default calling convention is used.

Description

This option specifies the default calling convention and argument-passing convention for an application.

The aspects of calling and argument passing controlled by this option are as follows:

- The calling mechanism (C or STDCALL): On IA-32 architecture, these mechanisms differ in how the stack register is adjusted when a procedure call returns. On Intel® 64 and IA-64 architectures, the only calling mechanism available is C; requests for the STDCALL mechanism are ignored.
- The argument passing mechanism (by value or by reference)
- Character-length argument passing (at the end of the argument list or after the argument address)
- The case of external names (uppercase or lowercase)
- The name decoration (prefix and suffix)

You can also use the ATTRIBUTES compiler directive to modify these conventions on an individual basis. Note that the effects of the ATTRIBUTES directive do not always match that of the iface option of the same name.

Option	Description
/iface:default	Tells the compiler to use the default calling conventions. These conventions are as follows: • The calling mechanism: C • The argument passing mechanism: by reference • Character-length argument passing: at end of argument list • The external name case: uppercase • The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 or IA-64 architecture; no suffix
/iface:cref	Tells the compiler to use the same conventions as /iface:default except that external names are lowercase.
/iface:cvf	Tells the compiler to use calling conventions compatible with Compaq Visual Fortran* and Microsoft Fortran PowerStation. These conventions are as follows: • The calling mechanism: STDCALL • The argument passing mechanism: by reference • Character-length argument passing: following the argument address • The external name case: uppercase • The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 or IA-64 architecture. On Windows* systems using IA-32 architecture, @n suffix where *n* is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.
/iface:mixed_str_len_arg	Specifies argument-passing conventions for hidden-length character arguments. This option tells the compiler that the hidden length passed for a character argument is to be placed immediately after its corresponding character argument in the argument list.

Option	Description
	This is the method used by Compaq Visual Fortran*. When porting mixed-language programs that pass character arguments, either this option must be specified correctly or the order of hidden length arguments must be changed in the source code. This option can be used in addition to other `/iface` options.
`/iface:std-call`	Tells the compiler to use the following conventions: • The calling mechanism: STDCALL • The argument passing mechanism: by value • Character-length argument passing: at the end of the argument list • The external name case: uppercase • The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 or IA-64 architecture. On Windows* systems using IA-32 architecture, @n suffix where *n* is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.
`/iface:stdref`	Tells the compiler to use the same conventions as `/iface:stdcall` except that argument passing is by reference.

CAUTION. On Windows systems, if you specify option `/iface:cref`, it overrides the default for external names and causes them to be lowercase. It is as if you specified "!dec$ attributes c, reference" for the external name.

If you specify option `/iface:cref` and want external names to be uppercase, you must explicitly specify option `/names:uppercase`.

CAUTION. On systems using IA-32 architecture, there must be agreement between the calling program and the called procedure as to which calling mechanism (C or STDCALL) is used or unpredictable errors may occur. If you change the default mechanism to STDCALL, you must use the ATTRIBUTES DEFAULT directive to reset the calling conventions for routines specified with the USEROPEN keyword in an OPEN statement and for comparison routines passed to the QSORT library routine.

Alternate Options

`/iface:cvf`	Linux and Mac OS X: None Windows: `/Gm`
`/iface:mixed_str_len_arg`	Linux and Mac OS X: `-mixed-str-len-arg` Windows: None
`/iface:nomixed_str_len_arg`	Linux and Mac OS X: `-nomixed-str-len-arg` Windows: None
`/iface:stdcall`	Linux and Mac OS X: None Windows: `/Gz`

include

See I.

inline

Specifies the level of inline function expansion.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/inline[:keyword]`

Arguments

keyword	Is the level of inline function expansion. Possible values are:	
	`none`	Disables inlining of user-defined functions. This is the same as specifying `manual`.
	`manual`	Disables inlining of user-defined functions. Fortran statement functions are always inlined.
	size	Enables inlining of any function. However, the compiler decides which functions are inlined. This option enables interprocedural optimizations and most speed optimizations.
	`speed`	Enables inlining of any function. This is the same as specifying `all`.
	`all`	Enables inlining of any function. However, the compiler decides which functions are inlined. This option enables interprocedural optimizations and all speed optimizations. This is the same as specifying `inline` with no *keyword*.

Default

OFF	The compiler inlines certain functions by default.

Description

This option specifies the level of inline function expansion.

Alternate Options

`inline all` or `inline speed`	Linux and Mac OS X: None Windows: `/Ob2 /Ot`

`inline size`	Linux and Mac OS X: None Windows: `/Ob2 /Os`
`inline manual`	Linux and Mac OS X: None Windows: `/Ob0`
`inline none`	Linux and Mac OS X: None Windows: `/Ob0`

See Also

-
- `finline-functions`

inline-debug-info, Qinline-debug-info

Produces enhanced source position information for inlined code. This is a deprecated option.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-inline-debug-info
```

Windows:

```
/Qinline-debug-info
```

Arguments

None

Default

OFF	No enhanced source position information is produced for inlined code.

Description

This option produces enhanced source position information for inlined code. This leads to greater accuracy when reporting the source location of any instruction. It also provides enhanced debug information useful for function call traceback.

To use this option for debugging, you must also specify a debug enabling option, such as `-g` (Linux) or `/debug` (Windows).

Alternate Options

Linux and Mac OS X: `-debug inline-debug-info`

Windows: None

inline-factor, Qinline-factor

Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-factor=`*n*

`-no-inline-factor`

Windows:

`/Qinline-factor=`*n*

`/Qinline-factor-`

Arguments

n	Is a positive integer specifying the percentage value. The default value is 100 (a factor of 1).

Default

`-no-inline-factor` or `/Qinline-factor-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the percentage multiplier that should be applied to all inlining options that define upper limits:

- `-inline-max-size` and `/Qinline-max-size`
- `-inline-max-total-size` and `/Qinline-max-total-size`
- `-inline-max-per-routine` and `/Qinline-max-per-routine`
- `-inline-max-per-compile` and `/Qinline-max-per-compile`

This option takes the default value for each of the above options and multiplies it by *n* divided by 100. For example, if 200 is specified, all inlining options that define upper limits are multiplied by a factor of 2. This option is useful if you do not want to individually increase each option limit.

If you specify `-no-inline-factor` (Linux and Mac OS X) or `/Qinline-factor-` (Windows), the following occurs:

- Every function is considered to be a small or medium function; there are no large functions.
- There is no limit to the size a routine may grow when inline expansion is performed.
- There is no limit to the number of times some routine may be inlined into a particular routine.
- There is no limit to the number of times inlining can be applied to a compilation unit.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase default limits, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

See Also

- Compiler Directed Inline Expansion of User Functions

inline-forceinline, Qinline-forceinline

Specifies that an inline routine should be inlined whenever the compiler can do so.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-inline-forceinline
```

Windows:

```
/Qinline-forceinline
```

Default

OFF	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies that a inline routine should be inlined whenever the compiler can do so. This causes the routines marked with an inline keyword or directive to be treated as if they were "forceinline".

NOTE. Because C++ member functions whose definitions are included in the class declaration are considered inline functions by default, using this option will also make these member functions "forceinline" functions.

The "forceinline" condition can also be specified by using the directive cDEC$ ATTRIBUTES FORCEINLINE.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS) or `/Qopt-report` (Windows).

CAUTION. When you use this option to change the meaning of inline to "forceinline", the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`
- Developer Directed Inline Expansion of User Functions
- Compiler Directed Inline Expansion of User Functions

inline-level, Ob

Specifies the level of inline function expansion.

IDE Equivalent

Windows: **Optimization > Inline Function Expansion**

Linux: None

Mac OS X: **Optimization > Inline Function Expansion**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-level=`*n*

Windows:

`/Ob`*n*

Arguments

n	Is the inline function expansion level. Possible values are 0, 1, and 2.

Default

`-inline-level=2` or `/Ob2`	This is the default if option `O2` is specified or is in effect by default. On Windows systems, this is also the default if option `O3` is specified.
`-inline-level=0` or `/Ob0`	This is the default if option `-O0` (Linux and Mac OS) or `/Od` (Windows) is specified.

Description

This option specifies the level of inline function expansion. Inlining procedures can greatly improve the run-time performance of certain programs.

Option	Description
`-inline-level=0` or `Ob0`	Disables inlining of user-defined functions. Note that statement functions are always inlined.
`-inline-level=1` or `Ob1`	Enables inlining when an inline keyword or an inline directive is specified.
`-inline-level=2` or `Ob2`	Enables inlining of any function at the compiler's discretion.

Alternate Options

Linux: `-Ob` (this is a deprecated option)

Mac OS X: None

Windows: None

See Also

-
-
- `inline`

inline-max-per-compile, Qinline-max-per-compile

Specifies the maximum number of times inlining may be applied to an entire compilation unit.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-per-compile=`*n*

`-no-inline-max-per-compile`

Windows:

`/Qinline-max-per-compile=`*n*

`/Qinline-max-per-compile-`

Arguments

n	Is a positive integer that specifies the number of times inlining may be applied.

Default

`-no-inline-max-per-compile` or `/Qinline-max-per-compile-`	The compiler uses default heuristics for inline routine expansion.

Description

This option the maximum number of times inlining may be applied to an entire compilation unit. It limits the number of times that inlining can be applied.

For compilations using Interprocedural Optimizations (IPO), the entire compilation is a compilation unit. For other compilations, a compilation unit is a file.

If you specify `-no-inline-max-per-compile` (Linux and Mac OS X) or `/Qinline-max-per-compile-` (Windows), there is no limit to the number of times inlining may be applied to a compilation unit.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

See Also

- Compiler Directed Inline Expansion of User Functions

inline-max-per-routine, Qinline-max-per-routine

Specifies the maximum number of times the inliner may inline into a particular routine.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-per-routine=`*n*

`-no-inline-max-per-routine`

Windows:

`/Qinline-max-per-routine=`*n*

`/Qinline-max-per-routine-`

Arguments

n	Is a positive integer that specifies the maximum number of times the inliner may inline into a particular routine.

Default

`-no-inline-max-per-routine` or `/Qinline-max-per-routine-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the maximum number of times the inliner may inline into a particular routine. It limits the number of times that inlining can be applied to any routine.

If you specify `-no-inline-max-per-routine` (Linux and Mac OS X) or `/Qinline-max-per-routine-` (Windows), there is no limit to the number of times some routine may be inlined into a particular routine.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

See Also

-
-
- `inline-factor`, `Qinline-factor`
- `opt-report`, `Qopt-report`

- Compiler Directed Inline Expansion of User Functions

inline-max-size, Qinline-max-size

Specifies the lower limit for the size of what the inliner considers to be a large routine.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-size=`*n*

`-no-inline-max-size`

Windows:

`/Qinline-max-size=`*n*

`/Qinline-max-size-`

Arguments

n	Is a positive integer that specifies the minimum size of what the inliner considers to be a large routine.

Default

`-no-inline-max-size` or `/Qinline-max-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the lower limit for the size of what the inliner considers to be a large routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be medium and large-size routines.

The inliner prefers to inline small routines. It has a preference against inlining large routines. So, any large routine is highly unlikely to be inlined.

If you specify `-no-inline-max-size` (Linux and Mac OS X) or `/Qinline-max-size-` (Windows), there are no large routines. Every routine is either a small or medium routine.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

inline-max-total-size, Qinline-max-total-size

Specifies how much larger a routine can normally grow when inline expansion is performed.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-total-size=n`

`-no-inline-max-total-size`

Windows:

`/Qinline-max-total-size=n`

`/Qinline-max-total-size-`

Arguments

n	Is a positive integer that specifies the permitted increase in the routine's size when inline expansion is performed.

Default

`-no-inline-max-total-size` or `/Qinline-max-total-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies how much larger a routine can normally grow when inline expansion is performed. It limits the potential size of the routine. For example, if 2000 is specified for *n*, the size of any routine will normally not increase by more than 2000.

If you specify `-no-inline-max-total-size` (Linux and Mac OS X) or `/Qinline-max-total-size-` (Windows), there is no limit to the size a routine may grow when inline expansion is performed.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

inline-min-size, Qinline-min-size

Specifies the upper limit for the size of what the inliner considers to be a small routine.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-min-size=`*n*

`-no-inline-min-size`

Windows:

`/Qinline-min-size=`*n*

`/Qinline-min-size-`

Arguments

n	Is a positive integer that specifies the maximum size of what the inliner considers to be a small routine.

Default

`-no-inline-min-size` or `/Qinline-min-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the upper limit for the size of what the inliner considers to be a small routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be small and medium-size routines.

The inliner has a preference to inline small routines. So, when a routine is smaller than or equal to the specified size, it is very likely to be inlined.

If you specify `-no-inline-min-size` (Linux and Mac OS X) or `/Qinline-min-size-` (Windows), there is no limit to the size of small routines. Every routine is a small routine; there are no medium or large routines.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

intconstant

Tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.

IDE Equivalent

Windows: **Compatibility > Use F77 Integer Constants**

Linux: None

Mac OS X: **Compatibility > Use F77 Integer Constants**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-intconstant
-nointconstant
```

Windows:

`/intconstant`

`/nointconstant`

Arguments

None

Default

`nointconstant`	The compiler uses the Fortran 95/90 default INTEGER type.

Description

This option tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.

With FORTRAN 77 semantics, the kind is determined by the value of the constant. All constants are kept internally by the compiler in the highest precision possible. For example, if you specify option `intconstant`, the compiler stores an integer constant of 14 internally as INTEGER(KIND=8) and converts the constant upon reference to the corresponding proper size. Fortran 95/90 specifies that integer constants with no explicit KIND are kept internally in the default INTEGER kind (KIND=4 by default).

Note that the internal precision for floating-point constants is controlled by option fpconstant.

Alternate Options

None

integer-size

Specifies the default KIND for integer and logical variables.

IDE Equivalent

Windows: **Data > Default Integer KIND**

Linux: None

Mac OS X: **Data > Default Integer KIND**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-integer-size` *size*

Windows:

`/integer-size:`*size*

Arguments

size	Is the size for integer and logical variables. Possible values are: 16, 32, or 64.

Default

`integer-size 32`	Integer and logical variables are 4 bytes long (INTEGER(KIND=4) and LOGICAL(KIND=4)).

Description

This option specifies the default size (in bits) for integer and logical variables.

Option	Description
`integer-size 16`	Makes default integer and logical variables 2 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=2).
`integer-size 32`	Makes default integer and logical variables 4 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=4).
`integer-size 64`	Makes default integer and logical variables 8 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=8).

Alternate Options

`integer-size 16`	Linux and Mac OS X: `-i2` Windows: `/4I2`
`integer-size 32`	Linux and Mac OS X: `-i4`

	Windows: `/4I4`
`integer-size 64`	Linux and Mac OS X: `-i8` Windows: `/4I8`

ip, Qip

Determines whether additional interprocedural optimizations for single-file compilation are enabled.

IDE Equivalent

Windows: **Optimization > Interprocedural Optimization**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ip`

`-no-ip`

Windows:

`/Qip`

`/Qip-`

Arguments

None

Default

OFF	Some limited interprocedural optimizations occur, including inline function expansion for calls to functions defined within the current source file. These optimizations are a subset of full intra-file interprocedural optimizations. Note that this setting is not the same as `-no-ip` (Linux and Mac OS X) or `/Qip-` (Windows).

Description

This option determines whether additional interprocedural optimizations for single-file compilation are enabled.

Options `-ip` (Linux and Mac OS X) and `/Qip` (Windows) enable additional interprocedural optimizations for single-file compilation.

Options `-no-ip` (Linux and Mac OS X) and `/Qip-` (Windows) may not disable inlining. To ensure that inlining of user-defined functions is disabled, specify `-inline-level=0`or `-fno-inline` (Linux and Mac OS X), or specify `/Ob0` (Windows).

Alternate Options

None

See Also

-
-
- `finline-functions`

ip-no-inlining, Qip-no-inlining

Disables full and partial inlining enabled by interprocedural optimization options.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-ip-no-inlining
```

Windows:

```
/Qip-no-inlining
```

Arguments

None

Default

OFF	Inlining enabled by interprocedural optimization options is performed.

Description

This option disables full and partial inlining enabled by the following interprocedural optimization options:

- On Linux and Mac OS X systems: `-ip` or `-ipo`
- On Windows systems: `/Qip`, `/Qipo`, or `/Ob2`

It has no effect on other interprocedural optimizations.

On Windows systems, this option also has no effect on user-directed inlining specified by option `/Ob1`.

Alternate Options

None

ip-no-pinlining, Qip-no-pinlining

Disables partial inlining enabled by interprocedural optimization options.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-ip-no-pinlining
```

Windows:

```
/Qip-no-pinlining
```

Arguments

None

Default

OFF	Inlining enabled by interprocedural optimization options is performed.

Description

This option disables partial inlining enabled by the following interprocedural optimization options:

- On Linux and Mac OS X systems: `-ip` or `-ipo`
- On Windows systems: `/Qip` or `/Qipo`

It has no effect on other interprocedural optimizations.

Alternate Options

None

IPF-flt-eval-method0, QIPF-flt-eval-method0

Tells the compiler to evaluate the expressions involving floating-point operands in the precision indicated by the variable types declared in the program. This is a deprecated option.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

```
-IPF-flt-eval-method0
```

Mac OS X:

None

Windows:

/QIPF-flt-eval-method0

Arguments

None

Default

OFF	Expressions involving floating-point operands are evaluated by default rules.

Description

This option tells the compiler to evaluate the expressions involving floating-point operands in the precision indicated by the variable types declared in the program.

By default, intermediate floating-point expressions are maintained in higher precision.

The recommended method to control the semantics of floating-point calculations is to use option -fp-model (Linux) or /fp (Windows).

Instead of using -IPF-flt-eval-method0 (Linux) or /QIPF-flt-eval-method0 (Windows), you can use -fp-model source (Linux) or /fp:source (Windows).

Alternate Options

None

See Also

-
-
- fp-model, fp

IPF-fltacc, QIPF-fltacc

Disables optimizations that affect floating-point accuracy. This is a deprecated option.

IDE Equivalent

Windows: **Floating Point > Floating-Point Accuracy**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux:

`-IPF-fltacc`

`-no-IPF-fltacc`

Mac OS X:

`None`

Windows:

`/QIPF-fltacc`

`/QIPF-fltacc-`

Arguments

None

Default

`-no-IPF-fltacc` or `/QIPF-fltacc-`	Optimizations are enabled that affect floating-point accuracy.

Description

This option disables optimizations that affect floating-point accuracy.

If the default setting is used, the compiler may apply optimizations that reduce floating-point accuracy.

You can use this option to improve floating-point accuracy, but at the cost of disabling some optimizations.

The recommended method to control the semantics of floating-point calculations is to use option `-fp-model` (Linux) or `/fp` (Windows).

Instead of using `-IPF-fltacc` (Linux) or `/QIPF-fltacc` (Windows), you can use `-fp-model precise` (Linux) or `/fp:precise` (Windows).

Instead of using `-no-IPF-fltacc` (Linux) or `/QIPF-fltacc-` (Windows), you can use `-fp-model fast` (Linux) or `/fp:fast` (Windows).

Alternate Options

None

See Also

-
-
- `fp-model, fp`

IPF-fma, QIPF-fma

See fma, Qfma.

IPF-fp-relaxed, QIPF-fp-relaxed

See fp-relaxed, Qfp-relaxed.

ipo, Qipo

Enables interprocedural optimization between files.

IDE Equivalent

Windows: **Optimization > Interprocedural Optimization**

General > Whole Program Optimization

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo[n]`

Windows:

`/Qipo[n]`

Arguments

n	Is an optional integer that specifies the number of object files the compiler should create. The integer must be greater than or equal to 0.

Default

OFF	Multifile interprocedural optimization is not enabled.

Description

This option enables interprocedural optimization between files. This is also called multifile interprocedural optimization (multifile IPO) or Whole Program Optimization (WPO).

When you specify this option, the compiler performs inline function expansion for calls to functions defined in separate files.

You cannot specify the names for the files that are created.

If *n* is 0, the compiler decides whether to create one or more object files based on an estimate of the size of the application. It generates one object file for small applications, and two or more object files for large applications.

If *n* is greater than 0, the compiler generates *n* object files, unless *n* exceeds the number of source files (*m*), in which case the compiler generates only *m* object files.

If you do not specify *n*, the default is 0.

Alternate Options

None

See Also

•

•

Optimizing Applications:

Interprocedural Optimization (IPO) Quick Reference

Interprocedural Optimization (IPO) Overview

Using IPO

ipo-c, Qipo-c

Tells the compiler to optimize across multiple files and generate a single object file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo-c`

Windows:

`/Qipo-c`

Arguments

None

Default

OFF	The compiler does not generate a multifile object file.

Description

This option tells the compiler to optimize across multiple files and generate a single object file (named ipo_out.o on Linux and Mac OS X systems; ipo_out.obj on Windows systems).

It performs the same optimizations as `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows), but compilation stops before the final link stage, leaving an optimized object file that can be used in further link steps.

Alternate Options

None

See Also

-
-
- `ipo`, `Qipo`

ipo-jobs, Qipo-jobs

Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo-jobs`*n*

Windows:

`/Qipo-jobs:`*n*

Arguments

n	Is the number of commands (jobs) to run simultaneously. The number must be greater than or equal to 1.

Default

`-ipo-jobs1` or `/Qipo-jobs:1`	One command (job) is executed in an interprocedural optimization parallel build.

Description

This option specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO). It should only be used if the link-time compilation is generating more than one object. In this case, each object is generated by a separate compilation, which can be done in parallel.

This option can be affected by the following compiler options:

- `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows) when applications are large enough that the compiler decides to generate multiple object files.
- `-ipo`*n* (Linux and Mac OS X) or `/Qipo`*n* (Windows) when *n* is greater than 1.
- `-ipo-separate` (Linux) or `/Qipo-separate` (Windows)

CAUTION. Be careful when using this option. On a multi-processor system with lots of memory, it can speed application build time. However, if *n* is greater than the number of processors, or if there is not enough memory to avoid thrashing, this option can increase application build time.

Alternate Options

None

See Also

-
-
- `ipo`, `Qipo`
- `ipo-separate`, `Qipo-separate`

ipo-S, Qipo-S

Tells the compiler to optimize across multiple files and generate a single assembly file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo-S`

Windows:

`/Qipo-S`

Arguments

None

Default

OFF	The compiler does not generate a multifile assembly file.

Description

This option tells the compiler to optimize across multiple files and generate a single assembly file (named ipo_out.s on Linux and Mac OS X systems; ipo_out.asm on Windows systems).

It performs the same optimizations as `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows), but compilation stops before the final link stage, leaving an optimized assembly file that can be used in further link steps.

Alternate Options

None

See Also

•

-
- ipo, Qipo

ipo-separate, Qipo-separate

Tells the compiler to generate one object file for every source file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-ipo-separate`

Mac OS X:

`None`

Windows:

`/Qipo-separate`

Arguments

None

Default

OFF	The compiler decides whether to create one or more object files.

Description

This option tells the compiler to generate one object file for every source file. It overrides any `-ipo` (Linux) or `/Qipo` (Windows) specification.

Alternate Options

None

See Also

-
-
- ipo, Qipo

isystem

Specifies a directory to add to the start of the system include path.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-isystem`*dir*

Windows:

None

Arguments

dir	Is the directory to add to the system include path.

Default

OFF	The default system include path is used.

Description

This option specifies a directory to add to the system include path. The compiler searches the specified directory for include files after it searches all directories specified by the `-I` compiler option but before it searches the standard system directories. This option is provided for compatibility with gcc.

Alternate Options

None

ivdep-parallel, Qivdep-parallel

Tells the compiler that there is no loop-carried memory dependency in the loop following an IVDEP directive.

IDE Equivalent

Windows: **Optimization > IVDEP Directive Memory Dependency**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux:

```
-ivdep-parallel
```

Mac OS X:

```
None
```

Windows:

```
/Qivdep-parallel
```

Arguments

None

Default

OFF	There may be loop-carried memory dependency in a loop that follows an IVDEP directive.

Description

This option tells the compiler that there is no loop-carried memory dependency in the loop following an IVDEP There may be loop-carried memory dependency in a loop that follows an IVDEP directive.
This has the same effect as specifying the IVDEP:LOOP directive.

Alternate Options

None

See Also

-
-

Optimizing Applications: Absence of Loop-carried Memory Dependency with IVDEP Directive

l

Tells the linker to search for a specified library when linking.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-l`*`string`*

Windows:

`None`

Arguments

`string`	Specifies the library (lib*`string`*) that the linker should search.

Default

OFF	The linker searches for standard libraries in standard directories.

Description

This option tells the linker to search for a specified library when linking.

When resolving references, the linker normally searches for libraries in several standard directories, in directories specified by the `L` option, then in the library specified by the `l` option.

The linker searches and processes libraries and object files in the order they are specified. So, you should specify this option following the last object file it applies to.

Alternate Options

None

See Also

-
- `L`

L

Tells the linker to search for libraries in a specified directory before searching the standard directories.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-L`*`dir`*

Windows:

`None`

Arguments

dir	Is the name of the directory to search for libraries.

Default

OFF	The linker searches the standard directories for libraries.

Description

This option tells the linker to search for libraries in a specified directory before searching for them in the standard directories.

Alternate Options

None

See Also

-
- `l`

LD

See dll.

libdir

Controls whether linker options for search libraries are included in object files generated by the compiler.

IDE Equivalent

Windows: **Libraries > Disable Default Library Search Rules** (`/libdir:[no]automatic`)

Libraries > Disable OBJCOMMENT Library Name in Object (`/libdir:[no]user`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

None

Windows:

/libdir[:*keyword*]

/nolibdir

Arguments

keyword Specifies the linker search options. Possible values are:

none	Prevents any linker search options from being included into the object file. This is the same as specifying /nolibdir.
[no]automatic	Determines whether linker search options for libraries automatically determined by the ifort command driver (default libraries) are included in the object file.
[no]user	Determines whether linker search options for libraries specified by the OBJCOMMENT source directives are included in the object file.
all	Causes linker search options for the following libraries: • Libraries automatically determined by the ifort command driver (default libraries) • Libraries specified by the OBJCOMMENT directive to be included in the object file This is the same as specifying /libdir.

Default

`/libdir:all`	Linker search options for libraries automatically determined by the `ifort` command driver (default libraries) and libraries specified by the OBJCOMMENT directive are included in the object file.

Description

This option controls whether linker options for search libraries (`/DEFAULTLIB:library`) are included in object files generated by the compiler.

The linker option `/DEFAULTLIB:library` adds one library to the list of libraries that the linker searches when resolving references. A library specified with `/DEFAULTLIB:library` is searched after libraries specified on the command line and before default libraries named in .obj files.

Alternate Options

`/libdir:none`	Linux and Mac OS X: None Windows: `/Zl`

libs

Tells the compiler which type of run-time library to link to.

IDE Equivalent

Windows: **Libraries > Runtime Library** (`/libs:{static|dll|qwin|qwins}`, `/threads`, `/dbglibs`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/libs[:`*keyword*`]`

Arguments

keyword — Specifies the type of run-time library to link to. Possible values are:

`static`	Specifies a single-threaded, static library (same as specifying `/libs`).
`dll`	Specifies a single-threaded, dynamic-link (DLL) library.
`qwin`	Specifies the Fortran QuickWin library.
`qwins`	Specifies the Fortran Standard Graphics library.

Default

`/libs:static` or `/libs` — The compiler links to a single-threaded, static run-time library.

Description

This option tells the compiler which type of run-time library to link to.

The library can be statically or dynamically loaded, multithreaded (`/threads`) or single-threaded, or debug (`/dbglibs`) or nondebug.

If you use the `/libs:dll` option and an unresolved reference is found in the DLL, it gets resolved when the program is executed, during program loading, reducing executable program size.

If you use the `/libs:qwin` or `/libs:qwins` option with the `/dll` option, the compiler issues a warning.

You cannot use the `/libs:qwin` option and options `/libs:dll /threads`.

The following table shows which options to specify for different run-time libraries:

Type of Library	Options Required	Alternate Option
Single-threaded, static	`/libs:static` or `/libs` or `/static`	`/ML`

Type of Library	Options Required	Alternate Option
Multithreaded	/libs:static /threads	/MT
Debug single-threaded	/libs:static /dbglibs	/MLd
Debug multithreaded	/libs:static /threads /dbglibs	/MTd
Single-threaded, dynamic-link libraries (DLLs)	/libs:dll	/MDs
Debug single-threaded, dynamic-link libraries (DLLs)	/libs:dll /dbglibs	/MDsd
Multithreaded DLLs	/libs:dll /threads	/MD
Multithreaded debug DLLs	/libs:dll /threads /dbglibs	/MDd
Fortran QuickWin multi-doc applications	/libs:qwin	/MW
Fortran standard graphics (QuickWin single-doc) applications	/libs:qwins	/MWs
Debug Fortran QuickWin multi-doc applications	/libs:qwin /dbglibs	None
Debug Fortran standard graphics (QuickWin single-doc) applications	/libs:qwins /dbglibs	None

Alternate Options

`/libs:dll`	Linux and Mac OS X:None Windows: `/MDs`
`/libs:static`	Linux and Mac OS X: None Windows: `/ML`
`/libs:qwin`	Linux and Mac OS X: None Windows: `/MW`
`/libs:qwins`	Linux and Mac OS X: None Windows: `/MWs`

link

Passes user-specified options directly to the linker at compile time.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/link`

Arguments

None

Default

OFF	No user-specified options are passed directly to the linker.

Description

This option passes user-specified options directly to the linker at compile time.

All options that appear following `/link` are passed directly to the linker.

Alternate Options

None

See Also

-
- `Xlinker`

logo

Displays the compiler version information.

IDE Equivalent

Windows: **General > Suppress Startup Banner** (`/nologo`)

Linux: None

Mac OS X: **General > Show Startup Banner** (`-V`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-logo`

`-nologo`

Windows:

`/logo`

`/nologo`

Arguments

None

Default

Linux and Mac OS X: `nologo`	The compiler version information is not displayed.
Windows: `logo`	The compiler version information is displayed.

Description

This option displays the startup banner, which contains the following compiler version information:

- ID: unique identification number for the compiler
- x.y.z: version of the compiler
- years: years for which the software is copyrighted

This option can be placed anywhere on the command line.

Alternate Options

Linux and Mac OS X: `-V`

Windows: None

lowercase, Qlowercase

See names.

m

Tells the compiler to generate optimized code specialized for the processor that executes your program.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-m[processor]`

Windows:

`None`

Arguments

processor Indicates the processor for which code is generated. Possible values are:

`ia32`	Generates code that will run on any Pentium or later processor. Disables any default extended instruction settings, and any previously set extended instruction settings. This value is only available on Linux systems using IA-32 architecture.
`sse`	This is the same as specifying `ia32`.
`sse2`	Generates code for Intel® Streaming SIMD Extensions 2 (Intel® SSE2). This value is only available on Linux systems.
`sse3`	Generates code for Intel® Streaming SIMD Extensions 3 (Intel® SSE3).
`ssse3`	Generates code for Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3).
`sse4.1`	Generates code for Intel® Streaming SIMD Extensions 4 Vectorizing Compiler and Media Accelerators.

Default

Linux systems: `-msse2` Mac OS X systems using IA-32 architecture: `-msse3`	For more information on the default values, see Arguments above.

Mac OS X systems using
Intel® 64 architecture:
`-mssse3`

Description

This option tells the compiler to generate optimized code specialized for the processor that executes your program.

Code generated with the values ia32, sse, sse2, or sse3 should execute on any compatible non-Intel processor with support for the corresponding instruction set.

Options `-x` and `-m` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

Alternate Options

Linux and Mac OS X: None

Windows: `/arch`

See Also

-
- `x`, `Qx`
- `ax`, `Qax`
- `arch`

m32, m64

Tells the compiler to generate code for a specific architecture.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-m32`

`-m64`

Windows:

`None`

Arguments

None

Default

OFF	The compiler's behavior depends on the host system.

Description

These options tell the compiler to generate code for a specific architecture.

Option	Description
`-m32`	Tells the compiler to generate code for IA-32 architecture.
`-m64`	Tells the compiler to generate code for Intel® 64 architecture.

The `-m32` and `-m64` options are the same as Mac OS* X options `-arch i386` and `-arch x86_64`, respectively. Note that these options are provided for compatibility with gcc. They are not related to the Intel® Fortran compiler option `arch`.

Alternate Options

None

map

Tells the linker to generate a link map file.

IDE Equivalent

Windows: **Linker > Debug > Generate Map File**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/map[:file]`

`/nomap`

Arguments

file	Is the name for the link map file. It can be a file name or a directory name.

Default

`/nomap`	No link map is generated.

Description

This option tells the linker to generate a link map file.

Alternate Options

None

map-opts, Qmap-opts

Maps one or more compiler options to their equivalent on a different operating system.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-map-opts`

Mac OS X:

`None`

Windows:

`/Qmap-opts`

Arguments

None

Default

OFF	No platform mappings are performed.

Description

This option maps one or more compiler options to their equivalent on a different operating system. The result is output to `stdout`.

On Windows systems, the options you provide are presumed to be Windows options, so the options that are output to `stdout` will be Linux equivalents.
On Linux systems, the options you provide are presumed to be Linux options, so the options that are output to `stdout` will be Windows equivalents.

The tool can be invoked from the compiler command line or it can be used directly.

No compilation is performed when the option mapping tool is used.

This option is useful if you have both compilers and want to convert scripts or makefiles.

NOTE. Compiler options are mapped to their equivalent on the architecture you are using.
For example, if you are using a processor with IA-32 architecture, you will only see equivalent options that are available on processors with IA-32 architecture.

Alternate Options

None

Example

The following command line invokes the option mapping tool, which maps the Linux options to Windows-based options, and then outputs the results to `stdout`:

```
ifort -map-opts -xP -O2
```

The following command line invokes the option mapping tool, which maps the Windows options to Linux-based options, and then outputs the results to `stdout`:

```
ifort /Qmap-opts /QxP /O2
```

Building Applications: Using the Option Mapping Tool

march

Tells the compiler to generate code for a specified processor.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux:

`-march=`*`processor`*

Mac OS X:

`None`

Windows:

`None`

Arguments

processor	Is the processor for which the compiler should generate code. Possible values are:
`pentium3`	Generates code for Intel® Pentium® III processors.
`pentium4`	Generates code for Intel® Pentium® 4 processors.
`core2`	Generates code for the Intel® Core 2™ processor family.

Default

OFF or `-march=pentium4`	On IA-32 architecture, the compiler does not generate processor-specific code unless it is told to do so. On systems using Intel® 64 architecture, the compiler generates code for Intel Pentium 4 processors.

Description

This option tells the compiler to generate code for a specified processor.

Specifying `-march=pentium4` sets `-mtune=pentium4`.

For compatibility, a number of historical *processor* values are also supported, but the generated code will not differ from the default.

Alternate Options

None

mcmodel

Tells the compiler to use a specific memory model to generate code and store data.

IDE Equivalent

None

Architectures

Intel® 64 architecture

Syntax

Linux:

`-mcmodel=`*`mem_model`*

Mac OS X:

`None`

Windows:

`None`

Arguments

`mem_model` Is the memory model to use. Possible values are:

`small`	Tells the compiler to restrict code and data to the first 2GB of address space. All accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.
`medium`	Tells the compiler to restrict code to the first 2GB; it places no memory restriction on data. Accesses of code can be done with IP-relative addressing, but accesses of data must be done with absolute addressing.
`large`	Places no memory restriction on code or data. All accesses of code and data must be done with absolute addressing.

Default

`-mcmodel=small` On systems using Intel® 64 architecture, the compiler restricts code and data to the first 2GB of address space. Instruction Pointer (IP)-relative addressing can be used to access code and data.

Description

This option tells the compiler to use a specific memory model to generate code and store data. It can affect code size and performance. If your program has COMMON blocks and local data with a total size smaller than 2GB, `-mcmodel=small` is sufficient. COMMONs larger than 2GB require `-mcmodel=medium` or `-mcmodel=large`. Allocation of memory larger than 2GB can be done with any setting of `-mcmodel`.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. IP-relative addressing is somewhat faster. So, the `small` memory model has the least impact on performance.

NOTE. When you specify `-mcmodel=medium` or `-mcmodel=large`, you must also specify compiler option `-shared-intel` to ensure that the correct dynamic versions of the Intel run-time libraries are used.

Alternate Options

None

Example

The following example shows how to compile using `-mcmodel`:

```
ifort -shared-intel -mcmodel=medium -o  prog prog.f
```

-
- `shared-intel`
- `fpic`

mcpu

This is a deprecated option. See mtune.

MD

Tells the linker to search for unresolved references in a multithreaded, dynamic-link run-time library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/MD`

`/MDd`

Arguments

None

Default

OFF	The linker searches for unresolved references in a single-threaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a multithreaded, dynamic-link (DLL) run-time library. This is the same as specifying options `/libs:dll /threads /dbglibs`. You can also specify `/MDd`, where `d` indicates a debug version.

Alternate Options

None

See Also

-
- `libs`
- `threads`

MDs

Tells the linker to search for unresolved references in a single-threaded, dynamic-link run-time library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/MDs`

`/MDsd`

Arguments

None

Default

OFF	The linker searches for unresolved references in a single-threaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a single-threaded, dynamic-link (DLL) run-time library.

You can also specify `/MDsd`, where *d* indicates a debug version.

Alternate Options

`/MDs`	Linux and Mac OS X: None Windows: `/libs:dll`

See Also

-
- libs

mdynamic-no-pic

Generates code that is not position-independent but has position-independent external references.

IDE Equivalent

None

Architectures

IA-32 architecture

Syntax

Linux:

None

Mac OS X:

-mdynamic-no-pic

Windows:

None

Arguments

None

Default

OFF	All references are generated as position independent.

Description

This option generates code that is not position-independent but has position-independent external references.

The generated code is suitable for building executables, but it is not suitable for building shared libraries.

This option may reduce code size and produce more efficient code. It overrides the `-fpic` compiler option.

Alternate Options

None

See Also

-
- `fpic`

MG

See winapp.

mieee-fp

See fltconsistency.

minstruction, Qinstruction

Determines whether MOVBE instructions are generated for Intel processors.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-minstruction=[no]movbe
```

Windows:

```
/Qinstruction:[no]movbe
```

Arguments

None

Default

`-minstruction=nomovbe` or `/Qinstruction:nomovbe` The compiler does not generate MOVBE instructions for Intel® Atom™ processors.

Description

This option determines whether MOVBE instructions are generated for Intel processors. To use this option, you must also specify `-xSSE3_ATOM` (Linux and Mac OS X) or `/QxSSE3_ATOM` (Windows).

If `-minstruction=movbe` or `/Qinstruction:movbe` is specified, the following occurs:

- MOVBE instructions are generated that are specific to the Intel® Atom™ processor.
- The options are ON by default when `-xSSE3_ATOM` or `/QxSSE3_ATOM` is specified.
- Generated executables can only be run on Intel® Atom™ processors or processors that support Intel® Streaming SIMD Extensions 3 (Intel® SSE3) and MOVBE.

If `-minstruction=nomovbe` or `/Qinstruction:nomovbe` is specified, the following occurs:

- The compiler optimizes code for the Intel® Atom™ processor, but it does not generate MOVBE instructions.
- Generated executables can be run on non-Intel® Atom™ processors that support Intel® SSE3.

Alternate Options

None

See Also

-
-
- `x, Qx`

mixed-str-len-arg

See iface.

mkl, Qmkl

Tells the compiler to link to certain parts of the Intel® Math Kernel Library (Intel® MKL).

IDE Equivalent

Windows: **Libraries > Use Intel(R) Math Kernel Library**

Linux: None

Mac OS X: **Libraries > Use Inte(R)l Math Kernel Library**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-mkl[=lib]`

Windows:

`/Qmkl[:lib]`

Arguments

lib Indicates the part of the library that the compiler should link to. Possible values are:

`parallel`	Tells the compiler to link using the threaded part of the Intel® MKL. This is the default if the option is specified with no *lib*.
`sequential`	Tells the compiler to link using the non-threaded part of the Intel® MKL.
`cluster`	Tells the compiler to link using the cluster part and the sequential part of the Intel® MKL.

Default

OFF	The compiler does not link to the Intel® MKL.

Description

This option tells the compiler to link to certain parts of the Intel® Math Kernel Library (Intel® MKL).

Alternate Options

None

ML

Tells the linker to search for unresolved references in a single-threaded, static run-time library.
This option has been deprecated.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/ML`

`/MLd`

Arguments

None

Default

Systems using Microsoft Visual Studio 2003: `/ML`	If Microsoft* Visual Studio* 2003 is being used, the linker searches for unresolved references in a single-threaded, static run-time library.
Systems using Microsoft Visual Studio 2005 or later: OFF	If Microsoft* Visual Studio* 2005 or greater is being used, or Microsoft* Visual Studio* Premier Partner Edition (VSPPE) has been installed, the linker searches for unresolved references in a multithreaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a single-threaded, static run-time library. It is only valid with Microsoft Visual Studio 2003, and is deprecated with later versions.

You can also specify `/MLd`, where `d` indicates a debug version.

Alternate Options

Linux: None

Mac OS X: None

Windows: `/libs:static`

See Also

-
- `libs`

module

Specifies the directory where module files should be placed when created and where they should be searched for.

IDE Equivalent

Windows: **Output > Module Path**

Linux: None

Mac OS X: **Output Files > Module Path**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-module` *path*

Windows:

`/module:`*path*

Arguments

path	Is the directory for module files.

Default

OFF	The compiler places module files in the current directory.

Description

This option specifies the directory (path) where module (.mod) files should be placed when created and where they should be searched for (USE statement).

Alternate Options

None

mp

See fltconsistency

multiple-processes, MP

Creates multiple processes that can be used to compile large numbers of source files at the same time.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-multiple-processes[=n]`

Windows:

`/MP[:n]`

Arguments

n	Is the maximum number of processes that the compiler should create.

Default

OFF	A single process is used to compile source files.

Description

This option creates multiple processes that can be used to compile large numbers of source files at the same time. It can improve performance by reducing the time it takes to compile source files on the command line.

This option causes the compiler to create one or more copies of itself, each in a separate process. These copies simultaneously compile the source files.

If *n* is not specified for this option, the default value is as follows:

- On Windows OS, the value is based on the setting of the NUMBER_OF_PROCESSORS environment variable.
- On Linux OS and Mac OS X, the value is 2.

This option applies to compilations, but not to linking or link-time code generation.

Alternate Options

None

mp1, Qprec

Improves floating-point precision and consistency.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-mp1`

Windows:

`/Qprec`

Arguments

None

Default

OFF	The compiler provides good accuracy and run-time performance at the expense of less consistent floating-point results.

Description

This option improves floating-point consistency. It ensures the out-of-range check of operands of transcendental functions and improves the accuracy of floating-point compares.

This option prevents the compiler from performing optimizations that change NaN comparison semantics and causes all values to be truncated to declared precision before they are used in comparisons. It also causes the compiler to use library routines that give better precision results compared to the X87 transcendental instructions.

This option disables fewer optimizations and has less impact on performance than option `flt-consistency` or `mp`.

Alternate Options

None

See Also

-
-
- `fltconsistency`
- `mp`

mrelax

Tells the compiler to pass linker option `-relax` *to the linker.*

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux and Mac OS X:

`-mrelax`

`-mno-relax`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

`-mno-relax`	The compiler does not pass `-relax` to the linker.

Description

This option tells the compiler to pass linker option `-relax` to the linker.

Alternate Options

None

MT

Tells the linker to search for unresolved references in a multithreaded, static run-time library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/MT`

`/MTd`

Arguments

None

Default

Systems using Intel® 64 architecture: `/MT /noreen-trancy`	On systems using Intel® 64 architecture, the linker searches for unresolved references in a multithreaded, static run-time library.
IA-32 architecture and IA-64 architecture: OFF	On systems using IA-32 architecture and IA-64 architecture, the linker searches for unresolved references in a single-threaded, static run-time library. However, on systems using IA-32 architecture, if option `Qvc8` is in effect, the linker searches for unresolved references in threaded libraries.

Description

This option tells the linker to search for unresolved references in a multithreaded, static run-time library. This is the same as specifying options `/libs:static /threads /noreentrancy`. You can also specify `/MTd`, where `d` indicates a debug version.

Alternate Options

None

See Also

-
- `Qvc`
- `libs`
- `threads`
- `reentrancy`

mtune

Performs optimizations for specific processors.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-mtune=`*`processor`*

Windows:

`None`

Arguments

`processor`	Is the processor for which the compiler should perform optimizations. Possible values are:

`generic`	Generates code for the compiler's default behavior.
`core2`	Optimizes for the Intel® Core™ 2 processor family, including support for MMX™, Intel® SSE, SSE2, SSE3 and SSSE3 instruction sets.
`pentium`	Optimizes for Intel® Pentium® processors.
`pentium-mmx`	Optimizes for Intel® Pentium® with MMX technology.
`pentiumpro`	Optimizes for Intel® Pentium® Pro, Intel Pentium II, and Intel Pentium III processors.
`pentium4`	Optimizes for Intel® Pentium® 4 processors.
`pentium4m`	Optimizes for Intel® Pentium® 4 processors with MMX technology.
`itanium2`	Optimizes for Intel® Itanium® 2 processors.
`itanium2-p9000`	Optimizes for the Dual-Core Intel® Itanium® 2 processor 9000 series. This option affects the order of the generated instructions, but the generated instructions are limited to Intel® Itanium® 2 processor instructions unless the program uses (executes) intrinsics specific to the Dual-Core Intel® Itanium® 2 processor 9000 series.

Default

generic	On systems using IA-32 and Intel® 64 architectures, code is generated for the compiler's default behavior.
itanium2-p9000	On systems using IA-64 architecture, the compiler optimizes for the Dual-Core Intel® Itanium® 2 processor 9000 series.

Description

This option performs optimizations for specific processors.

The resulting executable is backwards compatible and generated code is optimized for specific processors. For example, code generated with `-mtune=itanium2-p9000` will run correctly on single-core Itanium® 2 processors, but it might not run as fast as if it had been generated using `-mtune=itanium2`.

The following table shows on which architecture you can use each value.

	Architecture		
processor **Value**	**IA-32 architecture**	**Intel® 64 architecture**	**IA-64 architecture**
`generic`	X	X	X
`core2`	X	X	
`pentium`	X		
`pentium-mmx`	X		
`pentiumpro`	X		
`pentium4`	X		
`pentium4m`	X		
`itanium2`			X
`itanium2-p9000`			X

Alternate Options

`-mtune`	Linux: `-mcpu` (this is a deprecated option) Mac OS X: None Windows: None
`-mtune=itanium2`	Linux: `-mcpu=itanium2` (`-mcpu` is a deprecated option) Mac OS X: None Windows: `/G2`
`-mtune=itanium2-p9000`	Linux: `-mcpu=itanium2-p9000` (`-mcpu` is a deprecated option) Mac OS X: None Windows: `/G2-p9000`

multiple-processes, MP

Creates multiple processes that can be used to compile large numbers of source files at the same time.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-multiple-processes[=n]`

Windows:

`/MP[:n]`

Arguments

n	Is the maximum number of processes that the compiler should create.

Default

OFF	A single process is used to compile source files.

Description

This option creates multiple processes that can be used to compile large numbers of source files at the same time. It can improve performance by reducing the time it takes to compile source files on the command line.

This option causes the compiler to create one or more copies of itself, each in a separate process. These copies simultaneously compile the source files.

If *n* is not specified for this option, the default value is as follows:

- On Windows OS, the value is based on the setting of the NUMBER_OF_PROCESSORS environment variable.

- On Linux OS and Mac OS X, the value is 2.

This option applies to compilations, but not to linking or link-time code generation.

Alternate Options

None

MW

See libs.

MWs

See libs.

names

Specifies how source code identifiers and external names are interpreted.

IDE Equivalent

Windows: **External Procedures > Name Case Interpretation**

Linux: None

Mac OS X: **External Procedures > Name Case Interpretation**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-names keyword`

Windows:

`/names:keyword`

Arguments

keyword Specifies how to interpret the identifiers and external names in source code. Possible values are:

`lowercase`	Causes the compiler to ignore case differences in identifiers and to convert external names to lowercase.
`uppercase`	Causes the compiler to ignore case differences in identifiers and to convert external names to uppercase.
`as_is`	Causes the compiler to distinguish case differences in identifiers and to preserve the case of external names.

Default

`lowercase`	This is the default on Linux and Mac OS X systems. The compiler ignores case differences in identifiers and converts external names to lowercase.
`uppercase`	This is the default on Windows systems. The compiler ignores case differences in identifiers and converts external names to uppercase.

Description

This option specifies how source code identifiers and external names are interpreted. It can be useful in mixed-language programming.

This naming convention applies whether names are being defined or referenced.

You can use the ALIAS directive to specify an alternate external name to be used when referring to external subprograms.

CAUTION. On Windows systems, if you specify option `/iface:cref`, it overrides the default for external names and causes them to be lowercase. It is as if you specified "!dec$ attributes c, reference" for the external name.

If you specify option `/iface:cref` and want external names to be uppercase, you must explicitly specify option `/names:uppercase`.

Alternate Options

`names lowercase`	Linux and Mac OS X: `-lowercase` Windows: `/Qlowercase`
`names uppercase`	Linux and Mac OS X: `-uppercase` Windows: `/Quppercase`

See Also

-
- `iface`
- ALIAS Directive

nbs

See assume.

no-bss-init, Qnobss-init

Tells the compiler to place in the DATA section any variables explicitly initialized with zeros.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-no-bss-init
```

Windows:

```
/Qnobss-init
```

Arguments

None

Default

OFF	Variables explicitly initialized with zeros are placed in the BSS section.

Description

This option tells the compiler to place in the DATA section any variables explicitly initialized with zeros.

Alternate Options

Linux and Mac OS X: `-nobss-init` (this is a deprecated option)

Windows: None

nodefaultlibs

Prevents the compiler from using standard libraries when linking.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-nodefaultlibs`

Windows:

`None`

Arguments

None

Default

OFF	The standard libraries are linked.

Description

This option prevents the compiler from using standard libraries when linking.

Alternate Options

None

See Also

-
- nostdlib

nodefine

See D.

nofor-main

Specifies that the main program is not written in Fortran.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-nofor-main
```

Windows:

```
None
```

Arguments

None

Default

OFF	The compiler assumes the main program is written in Fortran.

Description

This option specifies that the main program is not written in Fortran. It is a link-time option that prevents the compiler from linking `for_main.o` into applications.

For example, if the main program is written in C and calls a Fortran subprogram, specify `-nofor-main` when compiling the program with the `ifort` command.

If you omit this option, the main program must be a Fortran program.

Alternate Options

None

noinclude

See X.

nolib-inline

Disables inline expansion of standard library or intrinsic functions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-nolib-inline`

Windows:

`None`

Arguments

None

Default

OFF	The compiler inlines many standard library and intrinsic functions.

Description

This option disables inline expansion of standard library or intrinsic functions. It prevents the unexpected results that can arise from inline expansion of these functions.

Alternate Options

None

nostartfiles

Prevents the compiler from using standard startup files when linking.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-nostartfiles
```

Windows:

```
None
```

Arguments

None

Default

OFF	The compiler uses standard startup files when linking.

Description

This option prevents the compiler from using standard startup files when linking.

Alternate Options

None

See Also

-
- nostdlib

nostdinc

See X.

nostdlib

Prevents the compiler from using standard libraries and startup files when linking.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-nostdlib`

Windows:

`None`

Arguments

None

Default

OFF	The compiler uses standard startup files and standard libraries when linking.

Description

This option prevents the compiler from using standard libraries and startup files when linking.

Alternate Options

None

See Also

-
- nodefaultlibs
- nostartfiles

nus

See assume.

o

Specifies the name for an output file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ofile`

Windows:

`None`

Arguments

file	Is the name for the output file. The space before *file* is optional.

Default

OFF	The compiler uses the default file name for an output file.

Description

This option specifies the name for an output file as follows:

- If `-c` is specified, it specifies the name of the generated object file.
- If `-S` is specified, it specifies the name of the generated assembly listing file.
- If -preprocess-only or `-P` is specified, it specifies the name of the generated preprocessor file.

Otherwise, it specifies the name of the executable file.

NOTE. If you misspell a compiler option beginning with "o", such as `-openmp`, `-opt-report`, etc., the compiler interprets the misspelled option as an `-o` *`file`* option. For example, say you misspell "`-opt-report`" as " `-opt-reprt`"; in this case, the compiler interprets the misspelled option as "`-o` pt-reprt", where pt-reprt is the output file name.

Alternate Options

Linux and Mac OS X: None

Windows: `/Fe`, `/exe`

See Also

-
- `Fe`
- `object`

O

Specifies the code optimization for applications.

IDE Equivalent

Windows: **General > Optimization** (`/Od`, `/O1`, `/O2`, `/O3`, `/fast`)

Optimization > Optimization (`/Od`, `/O1`, `/O2`, `/O3`, `/fast`)

Linux: None

Mac OS X: **General > Optimization Level** (`-O`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-O[n]`

Windows:

`/O[n]`

Arguments

n	Is the optimization level. Possible values are 1, 2, or 3. On Linux and Mac OS X systems, you can also specify 0.

Default

`O2`	Optimizes for code speed. This default may change depending on which other compiler options are specified. For details, see below.

Description

This option specifies the code optimization for applications.

Option	Description
`O` (Linux and Mac OS X)	This is the same as specifying `O2`.
`O0` (Linux and Mac OS X)	Disables all optimizations. On systems using IA-32 architecture and Intel® 64 architecture, this option sets option `-fno-omit-frame-pointer` and option `-fmath-errno`. This option causes certain `warn` options to be ignored. This is the default if you specify option `-debug` (with no keyword).
`O1`	Enables optimizations for speed and disables some optimizations that increase code size and affect speed. To limit code size, this option: • Enables global optimization; this includes data-flow analysis, code motion, strength reduction and test replacement, split-lifetime analysis, and instruction scheduling. • On systems using IA-64 architecture, it disables software pipelining, loop unrolling, and global code scheduling.

Option	Description
	On systems using IA-64 architecture, this option also enables optimizations for server applications (straight-line and branch-like code with a flat profile). The `O1` option sets the following options: • On Linux and Mac OS X systems: `-funroll-loops0`, `-nofltconsistency` (same as `-mno-ieee-fp`), `-fomit-frame-pointer`, `-ftz` • On Windows systems using IA-32 architecture: `/Qunroll0`, `/nofltconsistency` (same as `/Op-`), `/Oy`, `/Os`, `/Ob2`, `/Qftz` • On Windows systems using Intel® 64 architecture and IA-64 architecture: `/Qunroll0`, `/nofltconsistency` (same as `/Op-`), `/Os`, `/Ob2`, `/Qftz` The O1 option may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops.

`O2`	Enables optimizations for speed. This is the generally recommended optimization level.
	Vectorization is enabled at O2 and higher levels.
	On systems using IA-64 architecture, this option enables optimizations for speed, including global code scheduling, software pipelining, predication, and speculation.
	This option also enables:
	• Inlining of intrinsics
	• Intra-file interprocedural optimization, which includes:
	  • inlining
	  • constant propagation
	  • forward substitution
	  • routine attribute propagation
	  • variable address-taken analysis
	  • dead static function elimination

Option	Description
	• removal of unreferenced variables • The following capabilities for performance gain: • constant propagation • copy propagation • dead-code elimination • global register allocation • global instruction scheduling and control speculation • loop unrolling • optimized code selection • partial redundancy elimination • strength reduction/induction variable simplification • variable renaming • exception handling optimizations • tail recursions • peephole optimizations • structure assignment lowering and optimizations • dead store elimination On Windows systems, this option is the same as the `Ox` option. The `O2` option sets the following options: • On Windows systems using IA-32 architecture: `/Og`, `/Ot`, `/Oy`, `/Ob2`, `/Gs`, and `/Qftz` • On Windows systems using Intel® 64 architecture: `/Og`, `/Ot`, `/Ob2`, `/Gs`, and `/Qftz` On Linux and Mac OS X systems, if `-g` is specified, `O2` is turned off and `O0` is the default unless `O2` (or `O1` or `O3`) is explicitly specified in the command line together with `-g`.

Option	Description
	This option sets other options that optimize for code speed. The options set are determined by the compiler depending on which architecture and operating system you are using.
O3	Enables O2 optimizations plus more aggressive optimizations, such as prefetching, scalar replacement, and loop and memory access transformations. Enables optimizations for maximum speed, such as: • Loop unrolling, including instruction scheduling • Code replication to eliminate branches • Padding the size of certain power-of-two arrays to allow more efficient cache use. On Windows systems, the O3 option sets the /Ob2 option. On Linux and Mac OS X systems, the O3 option sets option -fomit-frame-pointer. On systems using IA-32 architecture or Intel® 64 architecture, when O3 is used with options -ax or -x (Linux) or with options /Qax or /Qx (Windows), the compiler performs more aggressive data dependency analysis than for O2, which may result in longer compilation times. On systems using IA-64 architecture, the O3 option enables optimizations for technical computing applications (loop-intensive code): loop optimizations and data prefetch. The O3 optimizations may not cause higher performance unless loop and memory access transformations take place. The optimizations may slow down code in some cases compared to O2 optimizations. The O3 option is recommended for applications that have loops that heavily use floating-point calculations and process large data sets.

The last O option specified on the command line takes precedence over any others.

NOTE. The options set by the O option may change from release to release.

Alternate Options

O1	Linux and Mac OS X: None Windows: /Od, /optimize:0, /nooptimize
O2	Linux and Mac OS X: None Windows: /optimize:1, /optimize:2
O3	Linux and Mac OS X: None Windows: /Ox, /optimize:3, /optimize:4
O4	Linux and Mac OS X: None Windows: /optimize:5

Optimizing Applications:

Compiler Optimizations Overview

Optimization Options Summary

Efficient Compilation

inline-level, Ob

Specifies the level of inline function expansion.

IDE Equivalent

Windows: **Optimization > Inline Function Expansion**

Linux: None

Mac OS X: **Optimization > Inline Function Expansion**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-level=`*n*

Windows:

`/Ob`*n*

Arguments

n	Is the inline function expansion level. Possible values are 0, 1, and 2.

Default

`-inline-level=2` or `/Ob2`	This is the default if option `O2` is specified or is in effect by default. On Windows systems, this is also the default if option `O3` is specified.
`-inline-level=0` or `/Ob0`	This is the default if option `-O0` (Linux and Mac OS) or `/Od` (Windows) is specified.

Description

This option specifies the level of inline function expansion. Inlining procedures can greatly improve the run-time performance of certain programs.

Option	Description
`-inline-level=0` or `Ob0`	Disables inlining of user-defined functions. Note that statement functions are always inlined.
`-inline-level=1` or `Ob1`	Enables inlining when an inline keyword or an inline directive is specified.
`-inline-level=2` or `Ob2`	Enables inlining of any function at the compiler's discretion.

Alternate Options

Linux: `-Ob` (this is a deprecated option)

Mac OS X: None

Windows: None

See Also

-
-
- `inline`

object

Specifies the name for an object file.

IDE Equivalent

Windows: **Output Files > Object File Name**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
None
```

Windows:

```
/object:file
```

Arguments

file	Is the name for the object file. It can be a file or directory name. A directory name must be followed by a backslash (\). If a special character appears within the file name or directory name, the file name or directory name must appear within quotes. To be safe, you should consider any non-ASCII numeric character to be a special character.

Default

OFF	An object file has the same name as the name of the first source file and a file extension of .obj.

Description

This option specifies the name for an object file.

If you specify this option and you omit `/c` or `/compile-only`, the `/object` option gives the object file its name.

On Linux and Mac OS X systems, this option is equivalent to specifying option `-o`*`file`* `-c`.

Alternate Options

Linux and Mac OS X: None

Windows: `/Fo`

Example

The following command shows how to specify a directory:

```
ifort /object:directorya\ end.f
```

If you do not add the backslash following a directory name, an executable is created. For example, the following command causes the compiler to create directorya.exe:

```
ifort /object:directorya end.f
```

The following commands show how to specify a subdirectory that contains a special character:

```
ifort /object:"blank subdirectory"\ end.f
```

```
ifort /object:"c:\my_directory"\ end.f
```

Od

Disables all optimizations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Od`

Arguments

None

Default

OFF	The compiler performs default optimizations.

Description

This option disables all optimizations. It can be used for selective optimizations, such as a combination of `/Od` and `/Og` (disables all optimizations except global optimizations), or `/Od` and `/Ob1` (disables all optimizations, but enables inlining).

This option also causes certain `/warn` options to be ignored.

On IA-32 architecture, this option sets the `/Oy-` option.

Alternate Options

Linux and Mac OS X: `-O0`

Windows: /optimize:0

See Also

-
- `O`

Og

Enables global optimizations.

IDE Equivalent

Windows: **Optimization > Global Optimizations**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Og`

`/Og-`

Arguments

None

Default

`/Og`	Global optimizations are enabled unless `/Od` is specified.

Description

This option enables global optimizations.

Alternate Options

None

onetrip, Qonetrip

Tells the compiler to follow the FORTRAN 66 Standard and execute DO loops at least once.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-onetrip`

Windows:

`/Qonetrip`

Arguments

None

Default

OFF	The compiler applies the current Fortran Standard semantics, which allows zero-trip DO loops.

Description

This option tells the compiler to follow the FORTRAN 66 Standard and execute DO loops at least once.

Alternate Options

Linux and Mac OS X: -1

Windows: /1

Op

This is a deprecated option. See fltconsistency.

openmp, Qopenmp

Enables the parallelizer to generate multi-threaded code based on the OpenMP directives.*

IDE Equivalent

Windows: **Language > Process OpenMP Directives**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp`

Windows:

`/Qopenmp`

Arguments

None

Default

OFF	No OpenMP multi-threaded code is generated by the compiler.

Description

This option enables the parallelizer to generate multi-threaded code based on the OpenMP* directives. The code can be executed in parallel on both uniprocessor and multiprocessor systems.

If you use this option, multithreaded libraries are used, but option `fpp` is not automatically invoked.

This option sets option `automatic`.

This option works with any optimization level. Specifying no optimization (`-O0` on Linux or `/Od` on Windows) helps to debug OpenMP applications.

NOTE. On Mac OS X systems, when you enable OpenMP*, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode or an error will be displayed.

Alternate Options

None

See Also

-
-
- `openmp-stubs`, `Qopenmp-stubs`

openmp-lib, Qopenmp-lib

Lets you specify an OpenMP run-time library to use for linking.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-openmp-lib` *type*

Mac OS X:

`None`

Windows:

`/Qopenmp-lib:`*type*

Arguments

type	Specifies the type of library to use; it implies compatibility levels. Possible values are:
`legacy`	Tells the compiler to use the legacy OpenMP* run-time library (libguide). This setting does not provide compatibility with object files created using other compilers. This is a deprecated option.
`compat`	Tells the compiler to use the compatibility OpenMP* run-time library (libiomp). This setting provides compatibility with object files created using Microsoft* and GNU* compilers.

Default

`-openmp-lib compat` or `/Qopenmp-lib:compat`	The compiler uses the compatibility OpenMP* run-time library (libiomp).

Description

This option lets you specify an OpenMP* run-time library to use for linking.

The legacy OpenMP run-time library is not compatible with object files created using OpenMP run-time libraries supported in other compilers.

The compatibility OpenMP run-time library is compatible with object files created using the Microsoft* OpenMP run-time library (vcomp) and GNU OpenMP run-time library (libgomp).

To use the compatibility OpenMP run-time library, compile and link your application using the `-openmp-lib compat` (Linux) or `/Qopenmp-lib:compat` (Windows) option. To use this option, you must also specify one of the following compiler options:

- Linux OS: `-openmp`, `-openmp-profile`, or `-openmp-stubs`
- Windows OS: `/Qopenmp`, `/Qopenmp-profile`, or `/Qopenmp-stubs`

On Windows* systems, the compatibility OpenMP* run-time library lets you combine OpenMP* object files compiled with the Microsoft* C/C++ compiler with OpenMP* object files compiled with the Intel C/C++ or Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

On Linux* systems, the compatibility Intel OpenMP* run-time library lets you combine OpenMP* object files compiled with the GNU* gcc or gfortran compilers with similar OpenMP* object files compiled with the Intel C/C++ or Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

You cannot link object files generated by the Intel® Fortran compiler to object files compiled by the GNU Fortran compiler, regardless of the presence or absence of the `-openmp` (Linux) or `/Qopenmp` (Windows) compiler option. This is because the Fortran run-time libraries are incompatible.

NOTE. The compatibility OpenMP run-time library is not compatible with object files created using versions of the Intel compiler earlier than 10.0.

Alternate Options

None

See Also

-
-
- `openmp`, `Qopenmp`
- `openmp-stubs`, `Qopenmp-stubs`
- `openmp-profile`, `Qopenmp-profile`

openmp-link, Qopenmp-link

Controls whether the compiler links to static or dynamic OpenMP run-time libraries.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp-link` *`library`*

Windows:

`/Qopenmp-link:`*`library`*

Arguments

`library`	Specifies the OpenMP library to use. Possible values are:	
	`static`	Tells the compiler to link to static OpenMP run-time libraries.
	`dynamic`	Tells the compiler to link to dynamic OpenMP run-time libraries.

Default

`-openmp-link dynamic` or `/Qopenmp-link:dynamic`	The compiler links to dynamic OpenMP run-time libraries. However, if option `static` is specified, the compiler links to static OpenMP run-time libraries.

Description

This option controls whether the compiler links to static or dynamic OpenMP run-time libraries.

To link to the static OpenMP run-time library (RTL) and create a purely static executable, you must specify `-openmp-link static` (Linux and Mac OS X) or `/Qopenmp-link:static` (Windows). However, we strongly recommend you use the default setting, `-openmp-link dynamic` (Linux and Mac OS X) or `/Qopenmp-link:dynamic` (Windows).

NOTE. Compiler options `-static-intel` and `-shared-intel` (Linux and Mac OS X) have no effect on which OpenMP run-time library is linked.

Alternate Options

None

openmp-profile, Qopenmp-profile

Enables analysis of OpenMP applications if Intel® Thread Profiler is installed.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-openmp-profile`

Mac OS X:

`None`

Windows:

`/Qopenmp-profile`

Arguments

None

Default

OFF	OpenMP applications are not analyzed.

Description

This option enables analysis of OpenMP* applications. To use this option, you must have previously installed Intel® Thread Profiler, which is one of the Intel® Threading Analysis Tools.

This option can adversely affect performance because of the additional profiling and error checking invoked to enable compatibility with the threading tools. Do not use this option unless you plan to use the Intel® Thread Profiler.

For more information about Intel® Thread Profiler, open the page associated with threading tools at Intel® Software Development Products.

Alternate Options

None

openmp-report, Qopenmp-report

Controls the OpenMP parallelizer's level of diagnostic messages.*

IDE Equivalent

Windows: **Compilation Diagnostics > OpenMP Diagnostic Level**

Linux: None

Mac OS X: **Compiler Diagnostics > OpenMP Report**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp-report[n]`

Windows:

`/Qopenmp-report[n]`

Arguments

n	Is the level of diagnostic messages to display. Possible values are:	
	`0`	No diagnostic messages are displayed.
	`1`	Diagnostic messages are displayed indicating loops, regions, and sections successfully parallelized.
	`2`	The same diagnostic messages are displayed as specified by openmp_report1 plus diagnostic messages indicating successful handling of MASTER constructs,

SINGLE constructs, CRITICAL constructs, ORDERED constructs, ATOMIC directives, and so forth.

Default

`-openmp-report1` or `/Qopenmp-report1`	If you do not specify *n*, the compiler displays diagnostic messages indicating loops, regions, and sections successfully parallelized. If you do not specify the option on the command line, the default is to display no messages.

Description

This option controls the OpenMP* parallelizer's level of diagnostic messages. To use this option, you must also specify `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows).

If this option is specified on the command line, the report is sent to `stdout`.

On Windows systems, if this option is specified from within the IDE, the report is included in the build log if the Generate Build Logs option is selected.

Alternate Options

None

See Also

-
-
- `openmp`, `Qopenmp`

Optimizing Applications:

Using Parallelism

OpenMP* Report

openmp-stubs, Qopenmp-stubs

Enables compilation of OpenMP programs in sequential mode.

IDE Equivalent

Windows: **Language > Process OpenMP Directives**

Linux: None

Mac OS X: **Language > Process OpenMP Directives**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp-stubs`

Windows:

`/Qopenmp-stubs`

Arguments

None

Default

OFF	The library of OpenMP function stubs is not linked.

Description

This option enables compilation of OpenMP programs in sequential mode. The OpenMP directives are ignored and a stub OpenMP library is linked.

Alternate Options

None

See Also

-
-
- `openmp`, `Qopenmp`

openmp-threadprivate, Qopenmp-threadprivate

Lets you specify an OpenMP threadprivate implementation.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-openmp-threadprivate` *type*

Mac OS X:

`None`

Windows:

`/Qopenmp-threadprivate:`*type*

Arguments

type Specifies the type of threadprivate implementation. Possible values are:

`legacy` Tells the compiler to use the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler. This setting does not provide compatibility with the implementation used by other compilers.

`compat` Tells the compiler to use the compatibility OpenMP* threadprivate implementation based on applying the thread-local attribute to each threadprivate variable. This setting provides compatibility with the implementation provided by the Microsoft* and GNU* compilers.

Default

`-openmp-threadprivate legacy` or `/Qopenmp-threadprivate:legacy`	The compiler uses the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler.

Description

This option lets you specify an OpenMP* threadprivate implementation.

The legacy OpenMP run-time library is not compatible with object files created using OpenMP run-time libraries supported in other compilers.

To use this option, you must also specify one of the following compiler options:

- Linux OS: `-openmp`, `-openmp-profile`, or `-openmp-stubs`
- Windows OS: `/Qopenmp`, `/Qopenmp-profile`, or `/Qopenmp-stubs`

The value specified for this option is independent of the value used for option `-openmp-lib` (Linux) or `/Qopenmp-lib` (Windows).

Alternate Options

None

opt-block-factor, Qopt-block-factor

Lets you specify a loop blocking factor.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-block-factor=`*n*

Windows:

`/Qopt-block-factor:`*n*

Arguments

n	Is the blocking factor. It must be an integer. The compiler may ignore the blocking factor if the value is 0 or 1.

Default

OFF	The compiler uses default heuristics for loop blocking.

Description

This option lets you specify a loop blocking factor.

Alternate Options

None

opt-jump-tables, Qopt-jump-tables

Enables or disables generation of jump tables for switch statements.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-jump-tables=`*`keyword`*

`-no-opt-jump-tables`

Windows:

`/Qopt-jump-tables:`*`keyword`*

`/Qopt-jump-tables-`

Arguments

keyword	Is the instruction for generating jump tables. Possible values are:	
	`never`	Tells the compiler to never generate jump tables. All switch statements are implemented as chains of if-then-elses. This is the same as specifying `-no-opt-jump-tables` (Linux and Mac OS) or `/Qopt-jump-tables-` (Windows).
	`default`	The compiler uses default heuristics to determine when to generate jump tables.
	`large`	Tells the compiler to generate jump tables up to a certain pre-defined size (64K entries).
	`n`	Must be an integer. Tells the compiler to generate jump tables up to *n* entries in size.

Default

`-opt-jump-tables=default` or `/Qopt-jump-tables:default`	The compiler uses default heuristics to determine when to generate jump tables for switch statements.

Description

This option enables or disables generation of jump tables for switch statements. When the option is enabled, it may improve performance for programs with large switch statements.

Alternate Options

None

opt-loadpair, Qopt-loadpair

Enables or disables loadpair optimization.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-loadpair`

`-no-opt-loadpair`

Mac OS X:

`None`

Windows:

`/Qopt-loadpair`

`/Qopt-loadpair-`

Arguments

None

Default

`-no-opt-loadpair` or `/Qopt-loadpair-`	Loadpair optimization is disabled unless option `O3` is specified.

Description

This option enables or disables loadpair optimization.

When `-O3` is specified on IA-64 architecture, loadpair optimization is enabled by default. To disable loadpair generation, specify `-no-opt-loadpair` (Linux) or `/Qopt-loadpair-` (Windows).

Alternate Options

None

opt-malloc-options

Lets you specify an alternate algorithm for malloc().

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-malloc-options=`*n*

Windows:

`None`

Arguments

n Specifies the algorithm to use for malloc(). Possible values are:

`0`	Tells the compiler to use the default algorithm for malloc(). This is the default.
`1`	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x10000000.
`2`	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x40000000.
`3`	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=0 and M_TRIM_THRESHOLD=-1.

4	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=0, M_TRIM_THRESHOLD=-1, M_TOP_PAD=4096.

Default

-opt-malloc-options=0	The compiler uses the default algorithm when malloc() is called. No call is made to mallopt().

Description

This option lets you specify an alternate algorithm for malloc().

If you specify a non-zero value for *n*, it causes alternate configuration parameters to be set for how malloc() allocates and frees memory. It tells the compiler to insert calls to mallopt() to adjust these parameters to malloc() for dynamic memory allocation. This may improve speed.

Alternate Options

None

See Also

•

malloc(3) man page

mallopt function (defined in malloc.h)

opt-mem-bandwidth, Qopt-mem-bandwidth

Enables performance tuning and heuristics that control memory bandwidth use among processors.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-mem-bandwidth`*n*

Mac OS X:

`None`

Windows:

`/Qopt-mem-bandwidth`*n*

Arguments

n	Is the level of optimizing for memory bandwidth usage. Possible values are:	
	`0`	Enables a set of performance tuning and heuristics in compiler optimizations that is optimal for serial code.
	`1`	Enables a set of performance tuning and heuristics in compiler optimizations for multithreaded code generated by the compiler.
	`2`	Enables a set of performance tuning and heuristics in compiler optimizations for parallel code such as Windows Threads, pthreads, and MPI code, besides multithreaded code generated by the compiler.

Default

`-opt-mem-bandwidth0` or `/Qopt-mem-bandwidth0`	For serial (non-parallel) compilation, a set of performance tuning and heuristics in compiler optimizations is enabled that is optimal for serial code.
`-opt-mem-bandwidth1` or `/Qopt-mem-bandwidth1`	If you specify compiler option `-parallel` (Linux) or `/Qparallel` (Windows), or `-openmp` (Linux) or `/Qopenmp` (Windows), a set of performance tuning and heuristics in compiler optimizations for multithreaded code generated by the compiler is enabled.

Description

This option enables performance tuning and heuristics that control memory bandwidth use among processors. It allows the compiler to be less aggressive with optimizations that might consume more bandwidth, so that the bandwidth can be well-shared among multiple processors for a parallel program.

For values of *n* greater than 0, the option tells the compiler to enable a set of performance tuning and heuristics in compiler optimizations such as prefetching, privatization, aggressive code motion, and so forth, for reducing memory bandwidth pressure and balancing memory bandwidth traffic among threads.

This option can improve performance for threaded or parallel applications on multiprocessors or multicore processors, especially when the applications are bounded by memory bandwidth.

Alternate Options

None

See Also

-
-
- `parallel`, `Qparallel`
- `openmp`, `Qopenmp`

opt-mod-versioning, Qopt-mod-versioning

Enables or disables versioning of modulo operations for certain types of operands.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

```
-opt-mod-versioning
-no-opt-mod-versioning
```

Mac OS X:

None

Windows:

/Qopt-mod-versioning

/Qopt-mod-versioning-

Arguments

None

Default

-no-opt-mod-versioning Versioning of modulo operations is disabled.
or/Qopt-mod-versioning-

Description

This option enables or disables versioning of modulo operations for certain types of operands. It is used for optimization tuning.

Versioning of modulo operations may improve performance for x mod y when modulus y is a power of 2.

Alternate Options

None

opt-multi-version-aggressive, Qopt-multi-version-aggressive

Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-opt-multi-version-aggressive`

`-no-opt-multi-version-aggressive`

Windows:

`/Qopt-multi-version-aggressive`

`/Qopt-multi-version-aggressive-`

Arguments

None

Default

`-no-opt-multi-version-aggressive` or `/Qopt-multi-version-aggressive-`	The compiler uses default heuristics when checking for pointer aliasing and scalar replacement.

Description

This option tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement. This option may improve performance.

Alternate Options

None

opt-prefetch, Qopt-prefetch

Enables or disables prefetch insertion optimization.

IDE Equivalent

Windows: **Optimization > Prefetch Insertion**

Linux: None

Mac OS X: **Optimization > Enable Prefetch Insertion**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-prefetch[=n]`

`-no-opt-prefetch`

Windows:

`/Qopt-prefetch[:n]`

`/Qopt-prefetch-`

Arguments

n	Is the level of detail in the report. Possible values are:	
	`0`	Disables software prefetching. This is the same as specifying `-no-opt-prefetch` (Linux and Mac OS X) or `/Qopt-prefetch-` (Windows).
	`1` to `4`	Enables different levels of software prefetching. If you do not specify a value for *n*, the default is `2` on IA-32 and Intel® 64 architecture; the default is `3` on IA-64 architecture. Use lower values to reduce the amount of prefetching.

Default

IA-64 architecture: `-opt-prefetch` or `/Qopt-prefetch`	On IA-64 architecture, prefetch insertion optimization is enabled.
IA-32 architecture and Intel® 64 architecture: `-no-opt-prefetch` or `/Qopt-prefetch-`	On IA-32 architecture and Intel® 64 architecture, prefetch insertion optimization is disabled.

Description

This option enables or disables prefetch insertion optimization. The goal of prefetching is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache.

On IA-64 architecture, this option is enabled by default if you specify option `O1` or higher. To disable prefetching at these optimization levels, specify `-no-opt-prefetch` (Linux and Mac OS X) or `/Qopt-prefetch-` (Windows).

On IA-32 architecture and Intel® 64 architecture, this option enables prefetching when higher optimization levels are specified.

Alternate Options

Linux and Mac OS X: `-prefetch` (this is a deprecated option)

Windows: `/Qprefetch` (this is a deprecated option)

opt-prefetch-initial-values, Qopt-prefetch-initial-values

Enables or disables prefetches that are issued before a loop is entered.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

```
-opt-prefetch-initial-values
-no-opt-prefetch-initial-values
```

Mac OS X:

```
None
```

Windows:

```
/Qopt-prefetch-initial-values
/Qopt-prefetch-initial-values-
```

Arguments

None

Default

`-opt-prefetch-initial-values` or `/Qopt-prefetch-initial-values` Prefetches are issued before a loop is entered.

Description

This option enables or disables prefetches that are issued before a loop is entered. These prefetches target the initial iterations of the loop.

When `-O1` or higher is specified on IA-64 architecture, prefetches are issued before a loop is entered. To disable these prefetches, specify `-no-opt-prefetch-initial-values` (Linux) or `/Qopt-prefetch-initial-values-` (Windows).

Alternate Options

None

opt-prefetch-issue-excl-hint, Qopt-prefetch-issue-excl-hint

Determines whether the compiler issues prefetches for stores with exclusive hint.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

```
-opt-prefetch-issue-excl-hint
-no-opt-prefetch-issue-excl-hint
```

Mac OS X:

None

Windows:

/Qopt-prefetch-issue-excl-hint

/Qopt-prefetch-issue-excl-hint-

Arguments

None

Default

-no-opt-prefetch-issue-excl-hint or/Qopt-prefetch-issue-excl-hint-	The compiler does not issue prefetches for stores with exclusive hint.

Description

This option determines whether the compiler issues prefetches for stores with exclusive hint. If option -opt-prefetch-issue-excl-hint (Linux) or /Qopt-prefetch-issue-excl-hint (Windows) is specified, the prefetches will be issued if the compiler determines it is beneficial to do so.

When prefetches are issued for stores with exclusive-hint, the cache-line is in "exclusive-mode". This saves on cache-coherence traffic when other processors try to access the same cache-line. This feature can improve performance tuning.

Alternate Options

None

opt-prefetch-next-iteration, Qopt-prefetch-next-iteration

Enables or disables prefetches for a memory access in the next iteration of a loop.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-prefetch-next-iteration`

`-no-opt-prefetch-next-iteration`

Mac OS X:

`None`

Windows:

`/Qopt-prefetch-next-iteration`

`/Qopt-prefetch-next-iteration-`

Arguments

None

Default

`-opt-prefetch-next-iteration` or `/Qopt-prefetch-next-iteration`	Prefetches are issued for a memory access in the next iteration of a loop.

Description

This option enables or disables prefetches for a memory access in the next iteration of a loop. It is typically used in a pointer-chasing loop.

When `-O1` or higher is specified on IA-64 architecture, prefetches are issued for a memory access in the next iteration of a loop. To disable these prefetches, specify `-no-opt-prefetch-next-iteration` (Linux) or `/Qopt-prefetch-next-iteration-` (Windows).

Alternate Options

None

opt-ra-region-strategy, Qopt-ra-region-strategy

Selects the method that the register allocator uses to partition each routine into regions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-opt-ra-region-strategy[=keyword]`

Windows:

`/Qopt-ra-region-strategy[:keyword]`

Arguments

keyword	Is the method used for partitioning. Possible values are:	
	`routine`	Creates a single region for each routine.
	`block`	Partitions each routine into one region per basic block.
	`trace`	Partitions each routine into one region per trace.
	`region`	Partitions each routine into one region per loop.
	`default`	The compiler determines which method is used for partitioning.

Default

`-opt-ra-region-strategy=default` or `/Qopt-ra-region-strategy:default`	The compiler determines which method is used for partitioning. This is also the default if `keyword` is not specified.

Description

This option selects the method that the register allocator uses to partition each routine into regions.

When setting `default` is in effect, the compiler attempts to optimize the tradeoff between compile-time performance and generated code performance.

This option is only relevant when optimizations are enabled (`O1` or higher).

Alternate Options

None

See Also

-
-
- `O`

opt-report, Qopt-report

Tells the compiler to generate an optimization report to stderr.

IDE Equivalent

Windows: Diagnostics > Optimization Diagnostics Level

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report [n]`

Windows:

`/Qopt-report[:n]`

Arguments

n	Is the level of detail in the report. On Linux OS and Mac OS X systems, a space must appear before the *n*. Possible values are:
	`0` Tells the compiler to generate no optimization report.
	`1` Tells the compiler to generate a report with the minimum level of detail.
	`2` Tells the compiler to generate a report with the medium level of detail.
	`3` Tells the compiler to generate a report with the maximum level of detail.

Default

`-opt-report 2` or `/Qopt-report:2`	If you do not specify *n*, the compiler generates a report with medium detail. If you do not specify the option on the command line, the compiler does not generate an optimization report.

Description

This option tells the compiler to generate an optimization report to `stderr`.

Alternate Options

None

See Also

-
-
- `opt-report-file`, `Qopt-report-file`

Optimizing Applications: Optimizer Report Generation

opt-report-file, Qopt-report-file

Specifies the name for an optimization report.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-file=`*`file`*

Windows:

`/Qopt-report-file:`*`file`*

Arguments

`file`	Is the name for the optimization report.

Default

OFF	No optimization report is generated.

Description

This option specifies the name for an optimization report. If you use this option, you do not have to specify `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`

Optimizing Applications: Optimizer Report Generation

opt-report-help, Qopt-report-help

Displays the optimizer phases available for report generation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-help`

Windows:

`/Qopt-report-help`

Arguments

None

Default

OFF	No optimization reports are generated.

Description

This option displays the optimizer phases available for report generation using `-opt-report-phase` (Linux and Mac OS X) or `/Qopt-report-phase` (Windows). No compilation is performed.

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`
- `opt-report-phase`, `Qopt-report-phase`

opt-report-phase, Qopt-report-phase

Specifies an optimizer phase to use when optimization reports are generated.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-phase=`*`phase`*

Windows:

`/Qopt-report-phase:`*`phase`*

Arguments

`phase` Is the phase to generate reports for. Some of the possible values are:

`ipo`	The Interprocedural Optimizer phase
`hlo`	The High Level Optimizer phase
`hpo`	The High Performance Optimizer phase
`ilo`	The Intermediate Language Scalar Optimizer phase
`ecg`	The Code Generator phase (Windows and Linux systems using IA-64 architecture only)
`ecg_swp`	The software pipelining component of the Code Generator phase (Windows and Linux systems using IA-64 architecture only)
`pgo`	The Profile Guided Optimization phase
`all`	All optimizer phases

Default

OFF	No optimization reports are generated.

Description

This option specifies an optimizer phase to use when optimization reports are generated. To use this option, you must also specify `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

This option can be used multiple times on the same command line to generate reports for multiple optimizer phases.

When one of the logical names for optimizer phases is specified for phase, all reports from that optimizer phase are generated.

To find all phase possibilities, use option `-opt-report-help` (Linux and Mac OS X) or `/Qopt-report-help` (Windows).

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`

opt-report-routine, Qopt-report-routine

Tells the compiler to generate reports on the routines containing specified text.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-routine=`*`string`*

Windows:

`/Qopt-report-routine:`*`string`*

Arguments

`string`	Is the text (string) to look for.

Default

OFF	No optimization reports are generated.

Description

This option tells the compiler to generate reports on the routines containing specified text as part of their name.

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`

opt-streaming-stores, Qopt-streaming-stores

Enables generation of streaming stores for optimization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-opt-streaming-stores` *keyword*

Windows:

`/Qopt-streaming-stores:`*keyword*

Arguments

keyword	Specifies whether streaming stores are generated. Possible values are:	
	`always`	Enables generation of streaming stores for optimization. The compiler optimizes under the assumption that the application is memory bound.
	`never`	Disables generation of streaming stores for optimization. Normal stores are performed.
	`auto`	Lets the compiler decide which instructions to use.

Default

`-opt-streaming-stores auto` or `/Qopt-streaming-stores:auto`	The compiler decides whether to use streaming stores or normal stores.

Description

This option enables generation of streaming stores for optimization. This method stores data with instructions that use a non-temporal buffer, which minimizes memory hierarchy pollution.

For this option to be effective, the compiler must be able to generate SSE2 (or higher) instructions. For more information, see compiler option `x` or `ax`.

This option may be useful for applications that can benefit from streaming stores.

Alternate Options

None

See Also

-
-
- ax, Qax
- x, Qx
- opt-mem-bandwidth, Qopt-mem-bandwidth, Qx

Optimizing Applications: Vectorization Support

opt-subscript-in-range, Qopt-subscript-in-range

Determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-opt-subscript-in-range
```

```
-no-opt-subscript-in-range
```

Windows:

```
/Qopt-subscript-in-range
```

```
/Qopt-subscript-in-range-
```

Arguments

None

Default

`-no-opt-subscript-in-range` or `/Qopt-subscript-in-range-`	The compiler assumes overflows in the intermediate computation of subscript expressions in loops.

Description

This option determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.

If you specify `-opt-subscript-in-range` (Linux and Mac OS X) or `/Qopt-subscript-in-range` (Windows), the compiler ignores any data type conversions used and it assumes no overflows in the intermediate computation of subscript expressions. This feature can enable more loop transformations.

Alternate Options

None

Example

The following shows an example where these options can be useful. m is declared as type integer(kind=8) (64-bits) and all other variables inside the subscript are declared as type integer(kind=4) (32-bits):

```
A[ i  + j  + ( n  + k) * m ]
```

optimize

See O.

Os

Enables optimizations that do not increase code size and produces smaller code size than O2.

IDE Equivalent

Windows: **Optimization > Favor Size or Speed**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Os`

Windows:

`/Os`

Arguments

None

Default

OFF	Optimizations are made for code speed. However, if `O1` is specified, `Os` is the default.

Description

This option enables optimizations that do not increase code size and produces smaller code size than `O2`. It disables some optimizations that increase code size for a small speed benefit.

This option tells the compiler to favor transformations that reduce code size over transformations that produce maximum performance.

Alternate Options

None

See Also

-
- `O`
- `Ot`

Ot

Enables all speed optimizations.

IDE Equivalent

Windows: **Optimization > Favor Size or Speed (`/Ot, /Os`)**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Ot`

Arguments

None

Default

`/Ot`	Optimizations are made for code speed. If `Od` is specified, all optimizations are disabled. If `O1` is specified, `Os` is the default.

Description

This option enables all speed optimizations.

Alternate Options

None

See Also

•

- O
- Os

Ox

See O.

fomit-frame-pointer, Oy

Determines whether EBP is used as a general-purpose register in optimizations.

IDE Equivalent

Windows: **Optimization > Omit Frame Pointers**

Linux: None

Mac OS X: **Optimization > Provide Frame Pointer**

Architectures

`-f[no-]omit-frame-pointer`: IA-32 architecture, Intel® 64 architecture

`/Oy[-]`: IA-32 architecture

Syntax

Linux and Mac OS X:

```
-fomit-frame-pointer
```

```
-fno-omit-frame-pointer
```

Windows:

```
/Oy
```

```
/Oy-
```

Arguments

None

Default

`-fomit-frame-pointer` or `/Oy`	EBP is used as a general-purpose register in optimizations. However, on Linux* and Mac OS X systems, the default is `-fno-omit-frame-pointer` if option `-O0` or `-g` is specified. On Windows* systems, the default is `/Oy-` if option `/Od` is specified.

Description

These options determine whether EBP is used as a general-purpose register in optimizations. Options `-fomit-frame-pointer` and `/Oy` allow this use. Options `-fno-omit-frame-pointer` and `/Oy-` disallow it.

Some debuggers expect EBP to be used as a stack frame pointer, and cannot produce a stack backtrace unless this is so. The `-fno-omit-frame-pointer` and `/Oy-` options direct the compiler to generate code that maintains and uses EBP as a stack frame pointer for all functions so that a debugger can still produce a stack backtrace without doing the following:

- For `-fno-omit-frame-pointer`: turning off optimizations with `-O0`
- For `/Oy-`: turning off `/O1`, `/O2`, or `/O3` optimizations

The `-fno-omit-frame-pointer` option is set when you specify option `-O0` or the `-g` option. The `-fomit-frame-pointer` option is set when you specify option `-O1`, `-O2`, or `-O3`.

The `/Oy` option is set when you specify the `/O1`, `/O2`, or `/O3` option. Option `/Oy-` is set when you specify the `/Od` option.

Using the `-fno-omit-frame-pointer` or `/Oy-` option reduces the number of available general-purpose registers by 1, and can result in slightly less efficient code.

Alternate Options

Linux and Mac OS X: `-fp` (this is a deprecated option)

Windows: None

p

Compiles and links for function profiling with gprof(1).

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-p`

Windows:

`None`

Arguments

None

Default

OFF	Files are compiled and linked without profiling.

Description

This option compiles and links for function profiling with gprof(1).

Alternate Options

Linux and Mac OS X: `-pg` (only available on systems using IA-32 architecture or Intel® 64 architecture), `-qp` (this is a deprecated option)

Windows: None

P

See preprocess-only.

pad, Qpad

Enables the changing of the variable and array memory layout.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-pad`

`-nopad`

Windows:

`/Qpad`

`/Qpad-`

Arguments

None

Default

`-nopad` or `/Qpad-` Variable and array memory layout is performed by default methods.

Description

This option enables the changing of the variable and array memory layout.

This option is effectively not different from the `align` option when applied to structures and derived types. However, the scope of `pad` is greater because it applies also to common blocks, derived types, sequence types, and structures.

Alternate Options

None

See Also

-
-
- `align`

pad-source, Qpad-source

Specifies padding for fixed-form source records.

IDE Equivalent

Windows: **Language > Pad Fixed Form Source Lines**

Linux: None

Mac OS X: **Language > Pad Fixed Form Source Lines**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-pad-source
-nopad-source
```

Windows:

```
/pad-source
/nopad-source
/Qpad-source
/Qpad-source-
```

Arguments

None

Default

`-nopad-source` or `/Qpad-` Fixed-form source records are not padded.
`source-`

Description

This option specifies padding for fixed-form source records. It tells the compiler that fixed-form source lines shorter than the statement field width are to be padded with spaces to the end of the statement field. This affects the interpretation of character and Hollerith literals that are continued across source records.

The default value setting causes a warning message to be displayed if a character or Hollerith literal that ends before the statement field ends is continued onto the next source record. To suppress this warning message, specify option `-warn nousage` (Linux and Mac OS X) or `/warn:nousage` (Windows).

Specifying `pad-source` or `/Qpad-source` can prevent warning messages associated with option `-warn usage` (Linux and Mac OS X) or `/warn:usage` (Windows).

Alternate Options

None

See Also

-
-
- `warn`

par-affinity, Qpar-affinity

Specifies thread affinity.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-par-affinity=[`*`modifier`*`,...]`*`type`*`[,`*`permute`*`][,`*`offset`*`]`

Mac OS X:

`None`

Windows:

`/Qpar-affinity:[`*`modifier`*`,...]`*`type`*`[,`*`permute`*`][,`*`offset`*`]`

Arguments

`modifier`	Is one of the following values: `granularity={fine|thread|core}`, `[no]respect`, `[no]verbose`, `[no]warnings`, `proclist=proc_list`. The default is `granularity=core, respect, and noverbose`. For information on value `proclist`, see Thread Affinity Interface in *Optimizing Applications*.
`type`	Indicates the thread affinity. This argument is required and must be one of the following values: `compact`, `disabled`, `explicit`, `none`, `scatter`, `logical`, `physical`. The default is `none`. Values `logical` and `physical` are deprecated. Use `compact` and `scatter`, respectively, with no *`permute`* value.
`permute`	Is a positive integer. You cannot use this argument with *`type`* setting `explicit`, `none`, or `disabled`. The default is 0.
`offset`	Is a positive integer. You cannot use this argument with *`type`* setting `explicit`, `none`, or `disabled`. The default is 0.

Default

OFF	The thread affinity is determined by the run-time environment.

Description

This option specifies thread affinity, which binds threads to physical processing units. It has the same effect as environment variable KMP_AFFINITY.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- Linux* OS: You have specified option `-parallel` or `-openmp` (or both).

  Windows* OS: You have specified option `/Qparallel` or `/Qopenmp` (or both).
- You are compiling the main program.

Alternate Options

None

See Also

-
-
- Thread Affinity Interface

par-num-threads, Qpar-num-threads

Specifies the number of threads to use in a parallel region.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-num-threads=`*n*

Windows:

`/Qpar-num-threads:`*n*

Arguments

n	Is the number of threads to use. It must be a positive integer.

Default

OFF	The number of threads to use is determined by the run-time environment.

Description

This option specifies the number of threads to use in a parallel region. It has the same effect as environment variable OMP_NUM_THREADS.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- Linux* OS and Mac OS* X: You have specified option `-parallel` or `-openmp` (or both).

  Windows* OS: You have specified option `/Qparallel` or `/Qopenmp` (or both).
- You are compiling the main program.

Alternate Options

None

par-report, Qpar-report

Controls the diagnostic information reported by the auto-parallelizer.

IDE Equivalent

Windows: **Compilation Diagnostics > Auto-Parallelizer Diagnostic Level**

Linux: None

Mac OS X: **Diagnostics > Auto-Parallelizer Report**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-report[`*n*`]`

Windows:

`/Qpar-report[n]`

Arguments

n	Is a value denoting which diagnostic messages to report. Possible values are:
0	Tells the auto-parallelizer to report no diagnostic information.
1	Tells the auto-parallelizer to report diagnostic messages for loops successfully auto-parallelized. The compiler also issues a "LOOP AUTO-PARALLELIZED" message for parallel loops.
2	Tells the auto-parallelizer to report diagnostic messages for loops successfully and unsuccessfully auto-parallelized.
3	Tells the auto-parallelizer to report the same diagnostic messages specified by 2 plus additional information about any proven or assumed dependencies inhibiting auto-parallelization (reasons for not parallelizing).

Default

`-par-report1` or `/Qpar-report1`	If you do not specify *n*, the compiler displays diagnostic messages for loops successfully auto-parallelized. If you do not specify the option on the command line, the default is to display no messages.

Description

This option controls the diagnostic information reported by the auto-parallelizer (parallel optimizer). To use this option, you must also specify `-parallel` (Linux and Mac OS X) or `/Qparallel` (Windows).

If this option is specified on the command line, the report is sent to `stdout`.

On Windows systems, if this option is specified from within the IDE, the report is included in the build log if the Generate Build Logs option is selected.

Alternate Options

None

par-runtime-control, Qpar-runtime-control

Generates code to perform run-time checks for loops that have symbolic loop bounds.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-runtime-control`

`-no-par-runtime-control`

Windows:

`/Qpar-runtime-control`

`/Qpar-runtime-control-`

Arguments

None

Default

`-no-par-runtime-control` The compiler uses default heuristics when checking loops.
or `/Qpar-runtime-control-`

Description

This option generates code to perform run-time checks for loops that have symbolic loop bounds.

If the granularity of a loop is greater than the parallelization threshold, the loop will be executed in parallel.

If you do not specify this option, the compiler may not parallelize loops with symbolic loop bounds if the compile-time granularity estimation of a loop can not ensure it is beneficial to parallelize the loop.

Alternate Options

None

par-schedule, Qpar-schedule

Lets you specify a scheduling algorithm or a tuning method for loop iterations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-schedule-`*`keyword`*`[=`*`n`*`]`

Windows:

`/Qpar-schedule-`*`keyword`*`[[:]`*`n`*`]`

Arguments

`keyword`	Specifies the scheduling algorithm or tuning method. Possible values are:	
	`auto`	Lets the compiler or run-time system determine the scheduling algorithm.
	`static`	Divides iterations into contiguous pieces.
	`static-balanced`	Divides iterations into even-sized chunks.
	`static-steal`	Divides iterations into even-sized chunks, but allows threads to steal parts of chunks from neighboring threads.
	`dynamic`	Gets a set of iterations dynamically.

`guided`	Specifies a minimum number of iterations.
`guided-analytical`	Divides iterations by using exponential distribution or dynamic distribution.
`runtime`	Defers the scheduling decision until run time.

n Is the size of the chunk or the number of iterations for each chunk. This setting can only be specified for static, dynamic, and guided. For more information, see the descriptions of each keyword below.

Default

static-balanced Iterations are divided into even-sized chunks and the chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.

Description

This option lets you specify a scheduling algorithm or a tuning method for loop iterations. It specifies how iterations are to be divided among the threads of the team.

This option affects performance tuning and can provide better performance during auto-parallelization.

Option	Description
`-par-schedule-auto` or `/Qpar-schedule-auto`	Lets the compiler or run-time system determine the scheduling algorithm. Any possible mapping may occur for iterations to threads in the team.
`-par-schedule-static` or `/Qpar-schedule-static`	Divides iterations into contiguous pieces (chunks) of size *n*. The chunks are assigned to threads in the team in a round-robin fashion in the order of the thread number. Note that the last chunk to be assigned may have a smaller number of iterations.

Option	Description
	If no *n* is specified, the iteration space is divided into chunks that are approximately equal in size, and each thread is assigned at most one chunk.
`-par-schedule-static-balanced` or `/Qpar-schedule-static-balanced`	Divides iterations into even-sized chunks. The chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.
`-par-schedule-static-steal` or `/Qpar-schedule-static-steal`	Divides iterations into even-sized chunks, but when a thread completes its chunk, it can steal parts of chunks assigned to neighboring threads. Each thread keeps track of L and U, which represent the lower and upper bounds of its chunks respectively. Iterations are executed starting from the lower bound, and simultaneously, L is updated to represent the new lower bound.
`-par-schedule-dynamic` or `/Qpar-schedule-dynamic`	Can be used to get a set of iterations dynamically. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations. Each chunk contains *n* iterations, except for the last chunk to be assigned, which may have fewer iterations. If no *n* is specified, the default is 1.
`-par-schedule-guided` or `/Qpar-schedule-guided`	Can be used to specify a minimum number of iterations. Assigns iterations to threads in chunks as the threads request them. The

Option	Description
	thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. For a chunk of size 1, the size of each chunk is proportional to the number of unassigned iterations divided by the number of threads, decreasing to 1. For an *n* with value *k* (greater than 1), the size of each chunk is determined in the same way with the restriction that the chunks do not contain fewer than *k* iterations (except for the last chunk to be assigned, which may have fewer than *k* iterations). If no *n* is specified, the default is 1.
`-par-schedule-guided-analytical` or `/Qpar-schedule-guided-analytical`	Divides iterations by using exponential distribution or dynamic distribution. The method depends on run-time implementation. Loop bounds are calculated with faster synchronization and chunks are dynamically dispatched at run time by threads in the team.
`-par-schedule-runtime` or `/Qpar-schedule-runtime`	Defers the scheduling decision until run time. The scheduling algorithm and chunk size are then taken from the setting of environment variable OMP_SCHEDULE.

Alternate Options

None

par-threshold, Qpar-threshold

Sets a threshold for the auto-parallelization of loops.

IDE Equivalent

Windows: **Optimization > Threshold For Auto-Parallelization**

Linux: None

Mac OS X: **Optimization > Threshold For Auto-Parallelization**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-threshold[n]`

Windows:

`/Qpar-threshold[[:]n]`

Arguments

n	Is an integer whose value is the threshold for the auto-parallelization of loops. Possible values are 0 through 100. If *n* is 0, loops get auto-parallelized always, regardless of computation work volume. If *n* is 100, loops get auto-parallelized when performance gains are predicted based on the compiler analysis data. Loops get auto-parallelized only if profitable parallel execution is almost certain. The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, *n*=50 directs the compiler to parallelize only if there is a 50% probability of the code speeding up if executed in parallel.

Default

`-par-threshold100` or `/Qpar-threshold100`	Loops get auto-parallelized only if profitable parallel execution is almost certain. This is also the default if you do not specify *n*.

Description

This option sets a threshold for the auto-parallelization of loops based on the probability of profitable execution of the loop in parallel. To use this option, you must also specify `-parallel` (Linux and Mac OS X) or `/Qparallel` (Windows).

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

Alternate Options

None

parallel, Qparallel

Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

IDE Equivalent

Windows: **Optimization > Parallelization**

Linux: None

Mac OS X: **Optimization > Parallelization**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-parallel`

Windows:

`/Qparallel`

Arguments

None

Default

OFF	Multithreaded code is not generated for loops that can be safely executed in parallel.

Description

This option tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

To use this option, you must also specify option `O2` or `O3`.

NOTE. On Mac OS X systems, when you enable automatic parallelization, you must also set the `DYLD_LIBRARY_PATH` environment variable within Xcode or an error will be displayed.

Alternate Options

None

See Also

-
-
- `par-report, Qpar-report`
- `par-affinity, Qpar-affinity`
- `par-num-threads, Qpar-num-threads`
- `par-runtime-control, Qpar-runtime-control`
- `par-schedule, Qpar-schedule`
- `O`

pc, Qpc

Enables control of floating-point significand precision.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-pc`*n*

Windows:

`/Qpc`*n*

Arguments

n	Is the floating-point significand precision. Possible values are:
`32`	Rounds the significand to 24 bits (single precision).
`64`	Rounds the significand to 53 bits (double precision).
`80`	Rounds the significand to 64 bits (extended precision).

Default

`-pc80` or `/Qpc64`	On Linux* and Mac OS* X systems, the floating-point significand is rounded to 64 bits. On Windows* systems, the floating-point significand is rounded to 53 bits.

Description

This option enables control of floating-point significand precision.

Some floating-point algorithms are sensitive to the accuracy of the significand, or fractional part of the floating-point value. For example, iterative operations like division and finding the square root can run faster if you lower the precision with the this option.

Note that a change of the default precision control or rounding mode, for example, by using the `-pc32` (Linux and Mac OS X) or `/Qpc32` (Windows) option or by user intervention, may affect the results returned by some of the mathematical functions.

Floating-point Operations: Floating-point Options Quick Reference

pdbfile

Specifies that any debug information generated by the compiler should be saved to a program database file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/pdbfile[:`*`file`*`]`

`/nopdbfile`

Arguments

file	Is the name of the program database file.

Default

/nopdbfile	Debug information generated by the compiler is not saved to a program database file.

Description

This option specifies that any debug information generated by the compiler should be saved to a program database file. To use this option, you must also specify /debug:full (or the equivalent).

If *file* is not specified, the default file name used is the name of your file with an extension of .pdb.

The compiler places debug information in the object file if you specify /nopdbfile or omit both /pdbfile and /debug:full (or the equivalent).

Alternate Options

None

See Also

-
- debug (Windows*)

pg

See p.

pie

Produces a position-independent executable on processors that support it.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-pie`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

OFF	The driver does not set up special run-time libraries and the linker does not perform the optimizations on executables.

Description

This option produces a position-independent executable on processors that support it. It is both a compiler option and a linker option. When used as a compiler option, this option ensures the linker sets up run-time libraries correctly.

Normally the object linked has been compiled with option `-fpie`.

When you specify `-pie`, it is recommended that you specify the same options that were used during compilation of the object.

Alternate Options

None

See Also

-
- fpie

prec-div, Qprec-div

Improves precision of floating-point divides.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prec-div`

`-no-prec-div`

Windows:

`/Qprec-div`

`/Qprec-div-`

Arguments

None

Default

`-prec-div` or `/Qprec-div`	The compiler uses this method for floating-point divides.

Description

This option improves precision of floating-point divides. It has a slight impact on speed.

With some optimizations, such as `-xSSE2` (Linux) or `/QxSSE2` (Windows), the compiler may change floating-point division computations into multiplication by the reciprocal of the denominator. For example, A/B is computed as A * (1/B) to improve the speed of the computation.

However, sometimes the value produced by this transformation is not as accurate as full IEEE division. When it is important to have fully precise IEEE division, use this option to disable the floating-point division-to-multiplication optimization. The result is more accurate, with some loss of performance.

If you specify `-no-prec-div` (Linux and Mac OS X) or `/Qprec-div-` (Windows), it enables optimizations that give slightly less precise results than full IEEE division.

Alternate Options

None

Floating-point Operations: Floating-point Options Quick Reference

prec-sqrt, Qprec-sqrt

Improves precision of square root implementations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-prec-sqrt
```

```
-no-prec-sqrt
```

Windows:

```
/Qprec-sqrt
```

```
/Qprec-sqrt-
```

Arguments

None

Default

`-no-prec-sqrt` or `/Qprec-sqrt-`	The compiler uses a faster but less precise implementation of square root. However, the default is `-prec-sqrt` or `/Qprec-sqrt` if any of the following options are specified: `/Od`, `/Op`, or `/Qprec` on Windows systems; `-O0`, `-mp` (or `-fltconsistency`), or `-mp1` on Linux and Mac OS X systems.

Description

This option improves precision of square root implementations. It has a slight impact on speed.

This option inhibits any optimizations that can adversely affect the precision of a square root computation. The result is fully precise square root implementations, with some loss of performance.

Alternate Options

None

preprocess-only

Causes the Fortran preprocessor to send output to a file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-preprocess-only
```

Windows:

```
/preprocess-only
```

Arguments

None

Default

OFF	Preprocessed source files are output to the compiler.

Description

This option causes the Fortran preprocessor to send output to a file.

The source file is preprocessed by the Fortran preprocessor, and the result for each source file is output to a corresponding .i or .i90 file.

Note that the source file is not compiled.

Alternate Options

Linux and Mac OS X: `-P`

Windows: `/P`

print-multi-lib

Prints information about where system libraries should be found.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-print-multi-lib
```

Windows:

```
None
```

Arguments

None

Default

OFF	No information is printed unless the option is specified.

Description

This option prints information about where system libraries should be found, but no compilation occurs. It is provided for compatibility with gcc.

Alternate Options

None

prof-data-order, Qprof-data-order

Enables or disables data ordering if profiling information is enabled.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

```
-prof-data-order
-no-prof-data-order
```

Mac OS X:

```
None
```

Windows:

```
/Qprof-data-order
/Qprof-data-order-
```

Arguments

None

Default

`-no-prof-data-order` or `/Qprof-data-order-`	Data ordering is disabled.

Description

This option enables or disables data ordering if profiling information is enabled. It controls the use of profiling information to order static program data items.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify `-prof-gen=globdata` (Linux) or `/Qprof-gen:globdata` (Windows).
- For feedback compilation, you must specify `-prof-use` (Linux) or `/Qprof-use` (Windows). You must not use multi-file optimization by specifying options such as option `-ipo` (Linux) or `/Qipo` (Windows), or option `-ipo-c` (Linux) or `/Qipo-c` (Windows).

Alternate Options

None

See Also

-
-
- prof-gen, Qprof-gen
- prof-use, Qprof-use
- prof-func-order, Qprof-func-order

prof-dir, Qprof-dir

Specifies a directory for profiling information output files.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-dir dir`

Windows:

`/Qprof-dir dir`

Arguments

dir	Is the name of the directory.

Default

OFF	Profiling output files are placed in the directory where the program is compiled.

Description

This option specifies a directory for profiling information output files (*.dyn and *.dpi). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Alternate Options

None

-
-

Floating-point Operations:

Profile-guided Optimization (PGO) Quick Reference

Coding Guidelines for Intel(R) Architectures

prof-file, Qprof-file

Specifies an alternate file name for the profiling summary files.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-file` *file*

Windows:

`/Qprof-file` *file*

Arguments

file	Is the name of the profiling summary file.

Default

OFF	The profiling summary files have the file name pgopti.*

Description

This option specifies an alternate file name for the profiling summary files. The *file* is used as the base name for files created by different profiling passes.

If you add this option to profmerge, the .dpi file will be named *file*.dpi instead of pgopti.dpi.

If you specify `-prof-genx` (Linux and Mac OS X) or `/Qprof-genx` (Windows) with this option, the .spi and .spl files will be named *file*.spi and *file*.spl instead of pgopti.spi and pgopti.spl.

If you specify `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) with this option, the .dpi file will be named *file*.dpi instead of pgopti.dpi.

Alternate Options

None

Optimizing Applications:

Profile-guided Optimizations Overview

Coding Guidelines for Intel(R) Architectures

Profile an Application

prof-func-groups

Enables or disables function grouping if profiling information is enabled.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux:

```
-prof-func-groups
```

```
-no-prof-func-groups
```

Mac OS X:

```
None
```

Windows:

```
None
```

Arguments

None

Default

`-no-prof-func-groups` Function grouping is disabled.

Description

This option enables or disables function grouping if profiling information is enabled.

A "function grouping" is a profiling optimization in which entire routines are placed either in the cold code section or the hot code section.

If profiling information is enabled by option `-prof-use`, option `-prof-func-groups` is set and function grouping is enabled. However, if you explicitly enable `-prof-func-order` (Linux) or `/Qprof-func-order` (Windows), function ordering is performed instead of function grouping.

If you want to disable function grouping when profiling information is enabled, specify `-no-prof-func-groups`.

To set the hotness threshold for function grouping, use option `-prof-hotness-threshold` (Linux) or `/Qprof-hotness-threshold` (Windows).

Alternate Options

`-func-groups` (this is a deprecated option)

See Also

-
- `prof-use, Qprof-use`
- `prof-func-order, Qprof-func-order`
- `prof-hotness-threshold, Qprof-hotness-threshold`

prof-func-order, Qprof-func-order

Enables or disables function ordering if profiling information is enabled.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-prof-func-order`

`-no-prof-func-order`

Mac OS X:

`None`

Windows:

`/Qprof-func-order`

`/Qprof-func-order-`

Arguments

None

Default

`-no-prof-func-order` or `/Qprof-func-order-`	Function ordering is disabled.

Description

This option enables or disables function ordering if profiling information is enabled.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify `-prof-gen=srcpos` (Linux) or `/Qprof-gen:srcpos` (Windows).
- For feedback compilation, you must specify `-prof-use` (Linux) or `/Qprof-use` (Windows). You must not use multi-file optimization by specifying options such as option `-ipo` (Linux) or `/Qipo` (Windows), or option `-ipo-c` (Linux) or `/Qipo-c` (Windows).

If you enable profiling information by specifying option `-prof-use` (Linux) or `/Qprof-use` (Windows), `-prof-func-groups` (Linux) and `/Qprof-func-groups` (Windows) are set and function grouping is enabled. However, if you explicitly enable `-prof-func-order` (Linux) or `/Qprof-func-order` (Windows), function ordering is performed instead of function grouping.

On Linux* systems, this option is only available for Linux linker 2.15.94.0.1, or later.

To set the hotness threshold for function grouping and function ordering, use option `-prof-hotness-threshold` (Linux) or `/Qprof-hotness-threshold` (Windows).

Alternate Options

None

The following example shows how to use this option on a Windows system:

```
ifort /Qprof-gen:globdata file1.f90 file2.f90 /exe:instrumented.exe
    ./instrumented.exe
ifort /Qprof-use /Qprof-func-order file1.f90 file2.f90 /exe:feedback.exe
```

The following example shows how to use this option on a Linux system:

```
ifort -prof-gen:globdata file1.f90 file2.f90 -o instrumented
    ./instrumented.exe
ifort -prof-use -prof-func-order file1.f90 file2.f90 -o feedback
```

See Also

-

- `prof-hotness-threshold, Qprof-hotness-threshold`
- prof-gen, Qprof-gen
- prof-use, Qprof-use
- prof-data-order, Qprof-data-order
- prof-func-groups

prof-gen, Qprof-gen

Produces an instrumented object file that can be used in profile-guided optimization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-gen[=keyword]`

`-no-prof-gen`

Windows:

`/Qprof-gen[:keyword]`

`/Qprof-gen-`

Arguments

keyword	Specifies details for the instrumented file. Possible values are:	
	`default`	Produces an instrumented object file. This is the same as specifying `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*) with no keyword.
	`srcpos`	Produces an instrumented object file that includes extra source position information. This option is the same as option `-prof-genx` (Linux* and Mac OS* X) or `/Qprof-genx` (Windows*), which are deprecated.
	`globdata`	Produces an instrumented object file that includes information for global data layout.

Default

`-no-prof-gen` or `/Qprof-gen-` Profile generation is disabled.

Description

This option produces an instrumented object file that can be used in profile-guided optimization. It gets the execution count of each basic block.

If you specify keyword `srcpos` or `globdata`, a static profile information file (.spi) is created. These settings may increase the time needed to do a parallel build using -prof-gen, because of contention writing the .spi file.

These options are used in phase 1 of the Profile Guided Optimizer (PGO) to instruct the compiler to produce instrumented code in your object files in preparation for instrumented execution.

Alternate Options

None

See Also

•

•

Optimizing Applications:

Basic PGO Options

Example of Profile-Guided Optimization

prof-genx, Qprof-genx

This is a deprecated option. See prof-gen keyword `srcpos`*.*

prof-hotness-threshold, Qprof-hotness-threshold

Lets you set the hotness threshold for function grouping and function ordering.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-prof-hotness-threshold=`*n*

Mac OS X:

`None`

Windows:

`/Qprof-hotness-threshold:n`

Arguments

n	Is the hotness threshold. *n* is a percentage having a value between 0 and 100 inclusive. If you specify 0, there will be no hotness threshold setting in effect for function grouping and function ordering.

Default

OFF	The compiler's default hotness threshold setting of 10 percent is in effect for function grouping and function ordering.

Description

This option lets you set the hotness threshold for function grouping and function ordering.

The "hotness threshold" is the percentage of functions in the application that should be placed in the application's hot region. The hot region is the most frequently executed part of the application. By grouping these functions together into one hot region, they have a greater probability of remaining resident in the instruction cache. This can enhance the application's performance.

For this option to take effect, you must specify option `-prof-use` (Linux) or `/Qprof-use` (Windows) and one of the following:

- On Linux systems: `-prof-func-groups` or `-prof-func-order`
- On Windows systems: `/Qprof-func-order`

Alternate Options

None

See Also

-
-
- prof-use, Qprof-use
- prof-func-groups
- prof-func-order, Qprof-func-order

prof-src-dir, Qprof-src-dir

Determines whether directory information of the source file under compilation is considered when looking up profile data records.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-src-dir`

`-no-prof-src-dir`

Windows:

`/Qprof-src-dir`

`/Qprof-src-dir-`

Arguments

None

Default

`-prof-src-dir` or `/Qprof-src-dir`	Directory information is used when looking up profile data records in the .dpi file.

Description

This option determines whether directory information of the source file under compilation is considered when looking up profile data records in the .dpi file. To use this option, you must also specify option `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows).

If the option is enabled, directory information is considered when looking up the profile data records within the .dpi file. You can specify directory information by using one of the following options:

- Linux and Mac OS X: `-prof-src-root` or `-prof-src-root-cwd`
- Windows: `/Qprof-src-root` or `/Qprof-src-root-cwd`

If the option is disabled, directory information is ignored and only the name of the file is used to find the profile data record.

Note that options `-prof-src-dir` (Linux and Mac OS X) and `/Qprof-src-dir` (Windows) control how the names of the user's source files get represented within the .dyn or .dpi files. Options `-prof-dir` (Linux and Mac OS X) and `/Qprof-dir` (Windows) specify the location of the .dyn or the .dpi files.

Alternate Options

None

See Also

-
-
- `prof-use, Qprof-use`
- `prof-src-root, Qprof-src-root`
- `prof-src-root-cwd, Qprof-src-root-cwd`

prof-src-root, Qprof-src-root

Lets you use relative directory paths when looking up profile data and specifies a directory as the base.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-src-root=`*`dir`*

Windows:

`/Qprof-src-root:dir`

Arguments

dir	Is the base for the relative paths.

Default

OFF	The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It lets you specify a directory as the base. The paths are relative to a base directory specified during the `-prof-gen` (Linux and Mac OS X) or `/Qprof-gen` (Windows) compilation phase.

This option is available during the following phases of compilation:

- Linux and Mac OS X: `-prof-gen` and `-prof-use` phases
- Windows: `/Qprof-gen` and `/Qprof-use` phases

When this option is specified during the `-prof-gen` or `/Qprof-gen` phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the `-prof-use` or `/Qprof-use` phase, it specifies a root directory that replaces the root directory specified at the `-prof-gen` or `/Qprof-gen` phase for forming the lookup keys.

To be effective, this option or option `-prof-src-root-cwd` (Linux and Mac OS X) or `/Qprof-src-root-cwd` (Windows) must be specified during the `-prof-gen` or `/Qprof-gen` phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

Alternate Options

None

Consider the initial `-prof-gen` compilation of the source file c:\user1\feature_foo\myproject\common\glob.f90:

```
ifort -prof-gen -prof-src-root=c:\user1\feature_foo\myproject -c common\glob.f90
```

For the -prof-use phase, the file glob.f90 could be moved into the directory c:\user2\feature_bar\myproject\common\glob.f90 and profile information would be found from the .dpi when using the following:

```
ifort -prof-use -prof-src-root=c:\user2\feature_bar\myproject -c common\glob.f90
```

If you do not use option -prof-src-root during the -prof-gen phase, by default, the -prof-use compilation can only find the profile data if the file is compiled in the c:\user1\feature_foo\my_project\common directory.

See Also

-
-

- prof-use, Qprof-use
- prof-src-dir, Qprof-src-dir
- prof-src-root-cwd, Qprof-src-root-cwd

prof-src-root-cwd, Qprof-src-root-cwd

Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-prof-src-root-cwd
```

Windows:

```
/Qprof-src-root-cwd
```

Arguments

None

Default

OFF	The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It specifies the current working directory as the base. To use this option, you must also specify option `-prof-use` (Linux and Mac OS) or `/Qprof-use` (Windows).

This option is available during the following phases of compilation:

- Linux and Mac OS X: `-prof-gen` and `-prof-use` phases
- Windows: `/Qprof-gen` and `/Qprof-use` phases

When this option is specified during the `-prof-gen` or `/Qprof-gen` phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the `-prof-use` or `/Qprof-use` phase, it specifies a root directory that replaces the root directory specified at the `-prof-gen` or `/Qprof-gen` phase for forming the lookup keys.

To be effective, this option or option `-prof-src-root` (Linux and Mac OS X) or `/Qprof-src-root` (Windows) must be specified during the `-prof-gen` or `/Qprof-gen` phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

Alternate Options

None

See Also

-
-
- `prof-gen, Qprof-gen`

prof-use, Qprof-use

Enables the use of profiling information during optimization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-use[=arg]`

`-no-prof-use`

Windows:

`/Qprof-use[:arg]`

`/Qprof-use-`

Arguments

arg	Specifies additional instructions. Possible values are:	
	`weighted`	Tells the profmerge utility to apply a weighting to the .dyn file values when creating the .dpi file to normalize the data counts when the training runs have differentexecution durations. This argument only has an effect when the compiler invokes the profmerge utility to create the .dpi file. This argument does not have an effect if the .dpi file was previously created without weighting.
	`[no]merge`	Enables or disables automatic invocation of the profmerge utility. The default is `merge`. Note that you cannot specify both

	`weighted` and `nomerge`. If you try to specify both values, a warning will be displayed and `nomerge` takes precedence.
`default`	Enables the use of profiling information during optimization. The profmerge utility is invoked by default. This value is the same as specifying `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) with no argument.

Default

`-no-prof-use` or `/Qprof-` Profiling information is not used during optimization.
`use-`

Description

This option enables the use of profiling information (including function splitting and function grouping) during optimization. It enables option `-fnsplit` (Linux) or `/Qfnsplit` (Windows).

This option instructs the compiler to produce a profile-optimized executable and it merges available profiling output files into a pgopti.dpi file.

Note that there is no way to turn off function grouping if you enable it using this option.

To set the hotness threshold for function grouping and function ordering, use option `-prof-hotness-threshold` (Linux) or `/Qprof-hotness-threshold` (Windows).

Alternate Options

None

See Also

-
-
- `prof-hotness-threshold, Qprof-hotness-threshold`

Optimizing Applications:

Basic PGO Options

Example of Profile-Guided Optimization

ansi-alias, Qansi-alias

Tells the compiler to assume that the program adheres to Fortran Standard type aliasability rules.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ansi-alias`

`-no-ansi-alias`

Windows:

`Qansi-alias`

`Qansi-alias-`

Arguments

None

Default

`-ansi-alias` or `/Qansi-alias`	Programs adhere to Fortran Standard type aliasability rules.

Description

This option tells the compiler to assume that the program adheres to type aliasability rules defined in the Fortran Standard.

For example, an object of type real cannot be accessed as an integer. For information on the rules for data types and data type constants, see "Data Types, Constants, and Variables" in the Language Reference.

This option directs the compiler to assume the following:

- Arrays are not accessed out of arrays' bounds.
- Pointers are not cast to non-pointer types and vice-versa.
- References to objects of two different scalar types cannot alias. For example, an object of type integer cannot alias with an object of type real or an object of type real cannot alias with an object of type double precision.

If your program adheres to the Fortran Standard type aliasability rules, this option enables the compiler to optimize more aggressively. If it doesn't adhere to these rules, then you should disable the option with `-no-ansi-alias` (Linux and Mac OS X) or `/Qansi-alias-` (Windows) so the compiler does not generate incorrect code.

Alternate Options

None

auto, Qauto

See automatic.

auto-scalar, Qauto-scalar

Causes scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute to be allocated to the run-time stack.

IDE Equivalent

Windows: **Data > Local Variable Storage** (`/Qsave`, `/Qauto`, `/Qauto_scalar`)

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-auto-scalar
```

Windows:

`/Qauto-scalar`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`	Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute are allocated to the run-time stack. Note that if option `recursive`, `-openmp` (Linux and Mac OS X), or `/Qopenmp` (Windows) is specified, the default is `automatic`.

Description

This option causes allocation of scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL to the run-time stack. It is as if they were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute (which include initialized locals) or that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across subroutine calls should appear in a SAVE statement.

You cannot specify option `save`, `auto`, or `automatic` with this option.

NOTE. On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `/automatic`, `/auto`, or `/Qauto` because arrays are allocated on the stack along with scalars. However, with `/Qauto-scalar`, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. `/Qauto-scalar` enables the compiler to make better choices about which variables should be kept in registers during program execution.

autodouble, Qautodouble

See real-size.

ax, Qax

Tells the compiler to generate multiple, processor-specific auto-dispatch code paths for Intel processors if there is a performance benefit.

IDE Equivalent

Windows: **Code Generation > Add Processor-Optimized Code Path**

Optimization > Generate Alternate Code Paths

Linux: None

Mac OS X: **Code Generation > Add Processor-Optimized Code Path**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-ax`*`processor`*

Windows:

`/Qax`*`processor`*

Arguments

processor	Indicates the processor for which code is generated. The following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (Intel® SSSE). Possible values are:

`SSE4.2`	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.
`SSE4.1`	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture. This replaces value S, which is deprecated.
`SSSE3`	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. For Mac OS* X systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.
`SSE3`	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. For Mac OS* X systems, this value is only supported on IA-32 architecture. This replaces value P, which is deprecated.
`SSE2`	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel®

	SSE2. This value is not available on Mac OS* X systems. This replaces value N, which is deprecated.

Default

OFF	No auto-dispatch code is generated. Processor-specific code is generated and is controlled by the setting of compiler option `-m` (Linux), compiler option `/arch` (Windows), or compiler option `-x` (Mac OS* X).

Description

This option tells the compiler to generate multiple, processor-specific auto-dispatch code paths for Intel processors if there is a performance benefit. It also generates a baseline code path. The baseline code is usually slower than the specialized code.

The baseline code path is determined by the architecture specified by the `-x` (Linux and Mac OS X) or `/Qx` (Windows) option. While there are defaults for the `-x` or `/Qx` option that depend on the operating system being used, you can specify an architecture for the baseline code that is higher or lower than the default. The specified architecture becomes the effective minimum architecture for the baseline code path.

If you specify both the `-ax` and `-x` options (Linux and Mac OS X) or the `/Qax` and `/Qx` options (Windows), the baseline code will only execute on processors compatible with the processor type specified by the `-x` or `/Qx` option.

This option tells the compiler to find opportunities to generate separate versions of functions that take advantage of features of the specified Intel® processor.

If the compiler finds such an opportunity, it first checks whether generating a processor-specific version of a function is likely to result in a performance gain. If this is the case, the compiler generates both a processor-specific version of a function and a baseline version of the function. At run time, one of the versions is chosen to execute, depending on the Intel processor in use. In this way, the program can benefit from performance gains on more advanced Intel processors, while still working properly on older processors.

You can use more than one of the processor values by combining them. For example, you can specify `-axSSE4.1,SSSE3` (Linux and Mac OS X) or `/QaxSSE4.1,SSSE3` (Windows). You cannot combine the old style, deprecated options and the new options. For example, you cannot specify `-axSSE4.1,T` (Linux and Mac OS X) or `/QaxSSE4.1,T` (Windows).

Previous values W and K are deprecated. The details on replacements are as follows:

- Mac OS X systems: On these systems, there is no exact replacement for W or K. You can upgrade to the default option `-msse3` (IA-32 architecture) or option `-mssse3` (Intel® 64 architecture).
- Windows and Linux systems: The replacement for W is `-msse2` (Linux) or `/arch:SSE2` (Windows). There is no exact replacement for K. However, on Windows systems, `/QaxK` is interpreted as `/arch:IA32`; on Linux systems, `-axK` is interpreted as `-mia32`. You can also do one of the following:
  - Upgrade to option `-msse2` (Linux) or option `/arch:SSE2` (Windows). This will produce one code path that is specialized for Intel® SSE2. It will not run on earlier processors
  - Specify the two option combination `-mia32 -axSSE2` (Linux) or `/arch:IA32 /QaxSSE2` (Windows). This combination will produce an executable that runs on any processor with IA-32 architecture but with an additional specialized Intel® SSE2 code path.

The `-ax` and `/Qax` options enable additional optimizations not enabled with option `-m` or option `/arch`.

Alternate Options

None

-
- `x`, `Qx`
- `m`
- `arch`

Qchkstk

Enables stack probing when the stack is dynamically expanded at run-time.

IDE Equivalent

Windows: **Run-time > Enable Stack Check Upon Expansion**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Qchkstk`

`/Qchkstk-`

Arguments

None

Default

`/Qchkstk`	Stack probing is enabled when the stack is dynamically expanded at run-time.

Description

This option enables stack probing when the stack is dynamically expanded at run-time.

It instructs the compiler to generate a call to `_chkstk`. The call will probe the requested memory and detect possible stack overflow.

To cancel the call to `_chkstk`, specify `/Qchkstk-`.

Alternate Options

None

common-args, Qcommon-args

See assume.

complex-limited-range, Qcomplex-limited-range

Determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

IDE Equivalent

Windows: **Floating point > Limit COMPLEX Range**

Linux: None

Mac OS X: **Floating point > Limit COMPLEX Range**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-complex-limited-range`

`-no-complex-limited-range`

Windows:

`/Qcomplex-limited-range`

`/Qcomplex-limited-range-`

Arguments

None

Default

`-no-complex-limited-range` or `/Qcomplex-limited-range-`	Basic algebraic expansions of some arithmetic operations involving data of type COMPLEX are disabled.

Description

This option determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

When the option is enabled, this can cause performance improvements in programs that use a lot of COMPLEX arithmetic. However, values at the extremes of the exponent range may not compute correctly.

Alternate Options

None

cpp, Qcpp

See fpp, Qfpp.

d-lines, Qd-lines

Compiles debug statements.

IDE Equivalent

Windows: **Language > Compile Lines With D in Column 1**

Linux: None

Mac OS X: **Language > Compile Lines With D in Column 1**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-d-lines
-nod-lines
```

Windows:

```
/d-lines
/nod-lines
/Qd-lines
```

Arguments

None

Default

`nod-lines`	Debug lines are treated as comment lines.

Description

This option compiles debug statements. It specifies that lines in fixed-format files that contain a D in column 1 (debug statements) should be treated as source code.

Alternate Options

Linux and Mac OS X: `-DD`

Windows: None

diag, Qdiag

Controls the display of diagnostic information.

IDE Equivalent

Windows: **Diagnostics > Disable Specific Diagnostics** (`/Qdiag-disable:id`)

Diagnostics > Level of Source Code Analysis (`/Qdiag-enable[:sc1,sc2,sc3]`)

Linux: None

Mac OS X: **Diagnostics > Disable Specific Diagnostics** (`-diag-disable id`)

Diagnostics > Level of Source Code Analysis (`-diag-enable [sc1,sc2,sc3]`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-`*`type diag-list`*

Windows:

`/Qdiag-`*`type:diag-list`*

Arguments

type

Is an action to perform on diagnostics. Possible values are:

`enable`	Enables a diagnostic message or a group of messages.
`disable`	Disables a diagnostic message or a group of messages.
`error`	Tells the compiler to change diagnostics to errors.
`warning`	Tells the compiler to change diagnostics to warnings.
`remark`	Tells the compiler to change diagnostics to remarks (comments).

diag-list

Is a diagnostic group or ID value. Possible values are:

`driver`	Specifies diagnostic messages issued by the compiler driver.
`vec`	Specifies diagnostic messages issued by the vectorizer.
`par`	Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).
`openmp`	Specifies diagnostic messages issued by the OpenMP* parallelizer.
`sc[n]`	Specifies diagnostic messages issued by the Source Checker. *n* can be any of the following: 1, 2, 3. For more details on these values, see below. This value is equivalent to deprecated value sv[n].
`warn`	Specifies diagnostic messages that have a "warning" severity level.
`error`	Specifies diagnostic messages that have an "error" severity level.
`remark`	Specifies diagnostic messages that are remarks or comments.

`cpu-dispatch`	Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default. This diagnostic group is only available on IA-32 architecture and Intel® 64 architecture.
`id[,id,...]`	Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each id.
`tag[,tag,...]`	Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each tag.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option controls the display of diagnostic information. Diagnostic messages are output to stderr unless compiler option `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows) is specified.

When *`diag-list`* value "warn" is used with the Source Checker (sc) diagnostics, the following behavior occurs:

- Option `-diag-enable warn` (Linux and Mac OS X) and `/Qdiag-enable:warn` (Windows) enable all Source Checker diagnostics except those that have an "error" severity level. They enable all Source Checker warnings, cautions, and remarks.
- Option `-diag-disable warn` (Linux and Mac OS X) and `/Qdiag-disable:warn` (Windows) disable all Source Checker diagnostics except those that have an "error" severity level. They suppress all Source Checker warnings, cautions, and remarks.

The following table shows more information on values you can specify for diag-list item sc.

diag-list Item	Description
sc[n]	The value of *n* for Source Checker messages can be any of the following: 1 Produces the diagnostics with severity level set to all critical errors. 2 Produces the diagnostics with severity level set to all errors. This is the default if n is not specified. 3 Produces the diagnostics with severity level set to all errors and warnings.

To control the diagnostic information reported by the vectorizer, use the `-vec-report` (Linux and Mac OS X) or `/Qvec-report` (Windows) option.

To control the diagnostic information reported by the auto-parallelizer, use the `-par-report` (Linux and Mac OS X) or `/Qpar-report` (Windows) option.

Alternate Options

enable vec	Linux and Mac OS X: `-vec-report` Windows: `/Qvec-report`
disable vec	Linux and Mac OS X: `-vec-report0` Windows: `/Qvec-report0`
enable par	Linux and Mac OS X: `-par-report` Windows: `/Qpar-report`
disable par	Linux and Mac OS X: `-par-report0` Windows: `/Qpar-report0`

Example

The following example shows how to enable diagnostic IDs 117, 230 and 450:

```
-diag-enable 117,230,450     ! Linux and Mac OS X systems
/Qdiag-enable:117,230,450    ! Windows systems
```

The following example shows how to change vectorizer diagnostic messages to warnings:

```
-diag-enable vec -diag-warning vec      ! Linux and Mac OS X systems
/Qdiag-enable:vec /Qdiag-warning:vec    ! Windows systems
```

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.

The following example shows how to disable all auto-parallelizer diagnostic messages:

```
-diag-disable par     ! Linux and Mac OS X systems

/Qdiag-disable:par    ! Windows systems
```

The following example shows how to produce Source Checker diagnostic messages for all critical errors:

```
-diag-enable sc1      ! Linux and Mac OS X systems

/Qdiag-enable:sc1     ! Windows system
```

The following example shows how to cause Source Checker diagnostics (and default diagnostics) to be sent to a file:

```
-diag-enable sc -diag-file=stat_ver_msg   ! Linux and Mac OS X systems

/Qdiag-enable:sc /Qdiag-file:stat_ver_msg ! Windows systems
```

Note that you need to enable the Source Checker diagnostics before you can send them to a file. In this case, the diagnostics are sent to file stat_ver_msg.diag. If a file name is not specified, the diagnostics are sent to name-of-the-first-source-file.diag.

The following example shows how to change all diagnostic warnings and remarks to errors:

```
-diag-error warn,remark    ! Linux and Mac OS X systems

/Qdiag-error:warn,remark   ! Windows systems
```

diag-dump, Qdiag-dump

Tells the compiler to print all enabled diagnostic messages and stop compilation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-dump`

Windows:

`/Qdiag-dump`

Arguments

None

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option tells the compiler to print all enabled diagnostic messages and stop compilation. The diagnostic messages are output to `stdout`.

This option prints the enabled diagnostics from all possible diagnostics that the compiler can issue, including any default diagnostics.

If `-diag-enable` *`diag-list`* (Linux and Mac OS X) or `/Qdiag-enable` *`diag-list`* (Windows) is specified, the print out will include the *`diag-list`* diagnostics.

Alternate Options

None

Example

The following example adds vectorizer diagnostic messages to the printout of default diagnostics:

```
-diag-enable vec -diag-dump          ! Linux and Mac OS X systems
/Qdiag-enable:vec /Qdiag-dump     ! Windows systems
```

diag, Qdiag

Controls the display of diagnostic information.

IDE Equivalent

Windows: **Diagnostics > Disable Specific Diagnostics** (`/Qdiag-disable:id`)

Diagnostics > Level of Source Code Analysis (`/Qdiag-enable[:sc1,sc2,sc3]`)

Linux: None

Mac OS X: **Diagnostics > Disable Specific Diagnostics** (`-diag-disable id`)

Diagnostics > Level of Source Code Analysis (`-diag-enable [sc1,sc2,sc3]`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-`*`type diag-list`*

Windows:

`/Qdiag-`*`type:diag-list`*

Arguments

type	Is an action to perform on diagnostics. Possible values are:

	`enable`	Enables a diagnostic message or a group of messages.
	`disable`	Disables a diagnostic message or a group of messages.
	`error`	Tells the compiler to change diagnostics to errors.
	`warning`	Tells the compiler to change diagnostics to warnings.
	`remark`	Tells the compiler to change diagnostics to remarks (comments).
`diag-list`	Is a diagnostic group or ID value. Possible values are:	
	`driver`	Specifies diagnostic messages issued by the compiler driver.
	`vec`	Specifies diagnostic messages issued by the vectorizer.
	`par`	Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).
	`openmp`	Specifies diagnostic messages issued by the OpenMP* parallelizer.
	`sc[n]`	Specifies diagnostic messages issued by the Source Checker. *`n`* can be any of the following: 1, 2, 3. For more details on these values, see below. This value is equivalent to deprecated value sv[n].
	`warn`	Specifies diagnostic messages that have a "warning" severity level.
	`error`	Specifies diagnostic messages that have an "error" severity level.
	`remark`	Specifies diagnostic messages that are remarks or comments.
	`cpu-dispatch`	Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default. This diagnostic group is only available on IA-32 architecture and Intel® 64 architecture.

`id[,id,...]`	Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each id.
`tag[,tag,...]`	Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each tag.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option controls the display of diagnostic information. Diagnostic messages are output to stderr unless compiler option `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows) is specified.

When *`diag-list`* value "warn" is used with the Source Checker (sc) diagnostics, the following behavior occurs:

- Option `-diag-enable warn` (Linux and Mac OS X) and `/Qdiag-enable:warn` (Windows) enable all Source Checker diagnostics except those that have an "error" severity level. They enable all Source Checker warnings, cautions, and remarks.
- Option `-diag-disable warn` (Linux and Mac OS X) and `/Qdiag-disable:warn` (Windows) disable all Source Checker diagnostics except those that have an "error" severity level. They suppress all Source Checker warnings, cautions, and remarks.

The following table shows more information on values you can specify for diag-list item sc.

diag-list **Item**	**Description**
`sc[n]`	The value of *`n`* for Source Checker messages can be any of the following:
	1 Produces the diagnostics with severity level set to all critical errors.

diag-list Item	Description
2	Produces the diagnostics with severity level set to all errors. This is the default if n is not specified.
3	Produces the diagnostics with severity level set to all errors and warnings.

To control the diagnostic information reported by the vectorizer, use the `-vec-report` (Linux and Mac OS X) or `/Qvec-report` (Windows) option.

To control the diagnostic information reported by the auto-parallelizer, use the `-par-report` (Linux and Mac OS X) or `/Qpar-report` (Windows) option.

Alternate Options

enable vec	Linux and Mac OS X: `-vec-report` Windows: `/Qvec-report`
disable vec	Linux and Mac OS X: `-vec-report0` Windows: `/Qvec-report0`
enable par	Linux and Mac OS X: `-par-report` Windows: `/Qpar-report`
disable par	Linux and Mac OS X: `-par-report0` Windows: `/Qpar-report0`

Example

The following example shows how to enable diagnostic IDs 117, 230 and 450:

```
-diag-enable 117,230,450     ! Linux and Mac OS X systems
/Qdiag-enable:117,230,450    ! Windows systems
```

The following example shows how to change vectorizer diagnostic messages to warnings:

```
-diag-enable vec -diag-warning vec      ! Linux and Mac OS X systems
/Qdiag-enable:vec /Qdiag-warning:vec    ! Windows systems
```

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.

The following example shows how to disable all auto-parallelizer diagnostic messages:

```
-diag-disable par     ! Linux and Mac OS X systems
/Qdiag-disable:par    ! Windows systems
```

The following example shows how to produce Source Checker diagnostic messages for all critical errors:

```
-diag-enable sc1      ! Linux and Mac OS X systems

/Qdiag-enable:sc1     ! Windows system
```

The following example shows how to cause Source Checker diagnostics (and default diagnostics) to be sent to a file:

```
-diag-enable sc -diag-file=stat_ver_msg   ! Linux and Mac OS X systems

/Qdiag-enable:sc /Qdiag-file:stat_ver_msg ! Windows systems
```

Note that you need to enable the Source Checker diagnostics before you can send them to a file. In this case, the diagnostics are sent to file stat_ver_msg.diag. If a file name is not specified, the diagnostics are sent to name-of-the-first-source-file.diag.

The following example shows how to change all diagnostic warnings and remarks to errors:

```
-diag-error warn,remark    ! Linux and Mac OS X systems

/Qdiag-error:warn,remark   ! Windows systems
```

diag-enable sc-include, Qdiag-enable:sc-include

Tells a source code analyzer to process include files and source files when issuing diagnostic messages.

IDE Equivalent

Windows: **Diagnostics > Analyze Include Files**

Linux: None

Mac OS X: **Diagnostics > Analyze Include Files**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-diag-enable sc-include`

Windows:

`/Qdiag-enable:sc-include`

Arguments

None

Default

OFF	The compiler issues certain diagnostic messages by default. If the Source Checker is enabled, include files are not analyzed by default.

Description

This option tells a source code analyzer (Source Checker) to process include files and source files when issuing diagnostic messages. Normally, when Source Checker diagnostics are enabled, only source files are analyzed.

To use this option, you must also specify `-diag-enable sc` (Linux and Mac OS X) or `/Qdiag-enable:sc` (Windows) to enable the Source Checker diagnostics, or `-diag-enable sc-parallel` (Linux and Mac OS X) or `/Qdiag-enable:sc-parallel` (Windows) to enable parallel lint.

Alternate Options

Linux and Mac OS X: `-diag-enable sv-include` (this is a deprecated option)

Windows: `/Qdiag-enable:sv-include` (this is a deprecated option)

Example

The following example shows how to cause include files to be analyzed as well as source files:

```
-diag-enable sc -diag-enable sc-include    ! Linux and Mac OS systems
/Qdiag-enable:sc /Qdiag-enable:sc-include  ! Windows systems
```

In the above example, the first compiler option enables Source Checker messages. The second compiler option causes include files referred to by the source file to be analyzed also.

See Also

-
-
- `diag-enable sc-parallel`, `Qdiag-enable:sc-parallel`
- `diag`, `Qdiag`

diag-enable sc-parallel, Qdiag-enable:sc-parallel

Enables analysis of parallelization in source code (parallel lint diagnostics).

IDE Equivalent

Windows: **Diagnostics > Level of Source Code Parallelization Analysis**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-diag-enable sc-parallel[`*n*`]`

Windows:

`/Qdiag-enable:sc-parallel[`*n*`]`

Arguments

n	Is the level of analysis to perform. Possible values are:

1	Produces the diagnostics with severity level set to all critical errors.
2	Tells the compiler to generate a report with the medium level of detail. Produces the diagnostics with severity level set to all errors. This is the default if *n* is not specified.
3	Produces the diagnostics with severity level set to all errors and warnings.

Default

OFF	The compiler does not analyze parallelization in source code.

Description

This option enables analysis of parallelization in source code (parallel lint diagnostics). Currently, this analysis uses OpenMP directives, so this option has no effect unless option `/Qopenmp` (Windows) or option `-openmp` (Linux and Mac OS X) is set.

Parallel lint performs interprocedural source code analysis to identify mistakes when using parallel directives. It reports various problems that are difficult to find, including data dependency and potential deadlocks.

Source Checker diagnostics (enabled by `/Qdiag-enable:sc` on Windows* OS or `-diag-enable sc` on Linux* OS and Mac OS* X) are a superset of parallel lint diagnostics. Therefore, if Source Checker diagnostics are enabled, the parallel lint option is not taken into account.

Alternate Options

None

See Also

-
-
- `diag`, `Qdiag`

diag-error-limit, Qdiag-error-limit

Specifies the maximum number of errors allowed before compilation stops.

IDE Equivalent

Windows: **Compilation Diagnostics > Error Limit**

Linux: None

Mac OS X: **Compiler Diagnostics > Error Limit**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-error-limit`*n*

`-no-diag-error-limit`

Windows:

`/Qdiag-error-limit:`*n*

`/Qdiag-error-limit-`

Arguments

n	Is the maximum number of error-level or fatal-level compiler errors allowed.

Default

30	A maximum of 30 error-level and fatal-level messages are allowed.

Description

This option specifies the maximum number of errors allowed before compilation stops. It indicates the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line.

If you specify `-no-diag-error-limit` (Linux and Mac OS X) or `/Qdiag-error-limit-` (Windows) on the command line, there is no limit on the number of errors that are allowed.

If the maximum number of errors is reached, a warning message is issued and the next file (if any) on the command line is compiled.

Alternate Options

Linux and Mac OS X: `-error-limit` and `-noerror-limit`

Windows: `/error-limit` and `/noerror-limit`

diag-file, Qdiag-file

Causes the results of diagnostic analysis to be output to a file.

IDE Equivalent

Windows: **Diagnostics > Diagnostics File**

Linux: None

Mac OS X: **Diagnostics > Diagnostics File**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-file[=`*`file`*`]`

Windows:

`/Qdiag-file[:`*`file`*`]`

Arguments

`file`	Is the name of the file for output.

Default

OFF	Diagnostic messages are output to stderr.

Description

This option causes the results of diagnostic analysis to be output to a file. The file is placed in the current working directory.

If *file* is specified, the name of the file is *file.diag*. The file can include a file extension; for example, if *file.ext* is specified, the name of the file is *file.ext*.

If *file* is not specified, the name of the file is *name-of-the-first-source-file.diag*. This is also the name of the file if the name specified for file conflicts with a source file name provided in the command line.

NOTE. If you specify `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows) and you also specify `-diag-file-append` (Linux and Mac OS X) or `/Qdiag-file-append` (Windows), the last option specified on the command line takes precedence.

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be output to a file named `my_diagnostics.diag`:

```
-diag-file=my_diagnostics       ! Linux and Mac OS X systems
/Qdiag-file:my_diagnostics      ! Windows systems
```

See Also

-
-
- `diag`, `Qdiag`
- `diag-file-append`, `Qdiag-file-append`

diag-file-append, Qdiag-file-append

Causes the results of diagnostic analysis to be appended to a file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-file-append[=file]`

Windows:

`/Qdiag-file-append[:file]`

Arguments

file	Is the name of the file to be appended to. It can include a path.

Default

OFF	Diagnostic messages are output to `stderr`.

Description

This option causes the results of diagnostic analysis to be appended to a file. If you do not specify a path, the driver will look for *file* in the current working directory.

If *file* is not found, then a new file with that name is created in the current working directory. If the name specified for file conflicts with a source file name provided in the command line. the name of the file is *name-of-the-first-source-file.diag*.

NOTE. If you specify `-diag-file-append` (Linux and Mac OS X) or `/Qdiag-file-append` (Windows) and you also specify `-diag-file` (Linux and Mac OS X) or `/Qdiag-file` (Windows), the last option specified on the command line takes precedence.

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be appended to a file named my_diagnostics.txt:

```
-diag-file-append=my_diagnostics.txt       ! Linux and Mac OS X systems
/Qdiag-file-append:my_diagnostics.txt      ! Windows systems
```

See Also

-
-
- diag, Qdiag
- diag-file, Qdiag-file

diag-id-numbers, Qdiag-id-numbers

Determines whether the compiler displays diagnostic messages by using their ID number values.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-diag-id-numbers
-no-diag-id-numbers
```

Windows:

```
/Qdiag-id-numbers
/Qdiag-id-numbers-
```

Arguments

None

Default

`-diag-id-numbers` or `/Qdiag-id-numbers`	The compiler displays diagnostic messages by using their ID number values.

Description

This option determines whether the compiler displays diagnostic messages by using their ID number values. If you specify `-no-diag-id-numbers` (Linux and Mac OS X) or `/Qdiag-id-numbers-` (Windows), mnemonic names are output for driver diagnostics only.

Alternate Options

None

See Also

-
-
- `diag`, `Qdiag`

diag-once, Qdiag-once

Tells the compiler to issue one or more diagnostic messages only once.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-diag-once`*`id`*`[,`*`id`*`,...]`

Windows:

`/Qdiag-once:`*`id`*`[,`*`id`*`,...]`

Arguments

id	Is the ID number of the diagnostic message. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each *id*.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option tells the compiler to issue one or more diagnostic messages only once.

Alternate Options

None

dps, Qdps

See altparam.

dyncom, Qdyncom

Enables dynamic allocation of common blocks at run time.

IDE Equivalent

Windows: **Data > Dynamic Common Blocks**

Linux: None

Mac OS X: **Data > Dynamic Common Blocks**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-dyncom "common1,common2,..."`

Windows:

```
/Qdyncom "common1,common2,..."
```

Arguments

common1,*common2*,...	Are the names of the common blocks to be dynamically allocated. The list of names must be within quotes.

Default

OFF	Common blocks are not dynamically allocated at run time.

Description

This option enables dynamic allocation of the specified common blocks at run time. For example, to enable dynamic allocation of common blocks a, b, and c at run time, use this syntax:

```
/Qdyncom "a,b,c"    ! on Windows systems

-dyncom "a,b,c"     ! on Linux and Mac OS X systems
```

The following are some limitations that you should be aware of when using this option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
- Only named common blocks can be designated as dynamic COMMON.
- An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

Alternate Options

None

See Also

-
-

Building Applications: Allocating Common Blocks

Qextend-source

See extend-source.

fast-transcendentals, Qfast-transcendentals

Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fast-transcendentals`

`-no-fast-transcendentals`

Windows:

`/Qfast-transcendentals`

`/Qfast-transcendentals-`

Default

`-fast-transcendentals` or `/Qfast-transcendentals`	The default depends on the setting of `-fp-model` (Linux and Mac OS X) or `/fp` (Windows). The default is ON if default setting `-fp-model fast` or `/fp:fast` is in effect. However, if a value-safe option such as `-fp-model precise` or `/fp:precise` is specified, the default is OFF.

Description

This option enables the compiler to replace calls to transcendental functions with implementations that may be faster but less precise.

It tells the compiler to perform certain optimizations on transcendental functions, such as replacing individual calls to sine in a loop with a single call to a less precise vectorized sine library routine.

This option has an effect only when specified with one of the following options:

- Windows* OS: `/fp:except` or `/fp:precise`
- Linux* OS and Mac OS* X: `-fp-model except` or `-fp-model precise`

You cannot use this option with option `-fp-model strict` (Linux and Mac OS X) or `/fp:strict` (Windows).

Alternate Options

None

See Also

-
-
- `fp-model, fp`

fma, Qfma

Enables the combining or contraction of floating-point multiplications and add or subtract operations.

IDE Equivalent

Windows: **Floating Point > Contract Floating-Point Operations**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux:

```
-fma
-no-fma
```

Mac OS X:

None

Windows:

/Qfma

/Qfma-

Arguments

None

Default

-fma or/Qfma	Floating-point multiplications and add/subtract operations are combined. However, if you specify -fp-model strict (Linux) or /fp:strict (Windows), but do not explicitly specify -fma or /Qfma, the default is -no-fma or /Qfma-.

Description

This option enables the combining or contraction of floating-point multiplications and add or subtract operations into a single operation.

Alternate Options

Linux: -IPF-fma (this is a deprecated option)

Windows: /QIPF-fma (this is a deprecated option)

See Also

-
-
- fp-model, fp

Floating-point Operations: Floating-point Options Quick Reference

falign-functions, Qfnalign

Tells the compiler to align functions on an optimal byte boundary.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-falign-functions[=n]`

`-fno-align-functions`

Windows:

`/Qfnalign[:n]`

`/Qfnalign-`

Arguments

n	Is the byte boundary for function alignment. Possible values are 2 or 16.

Default

`-fno-align-functions` or `/Qfnalign-`	The compiler aligns functions on 2-byte boundaries. This is the same as specifying `-falign-functions=2` (Linux and Mac OS X) or `/Qfnalign:2` (Windows).

Description

This option tells the compiler to align functions on an optimal byte boundary. If you do not specify *n*, the compiler aligns the start of functions on 16-byte boundaries.

Alternate Options

None

fnsplit, Qfnsplit

Enables function splitting.

IDE Equivalent

None

Architectures

`/Qfnsplit[-]`: IA-32 architecture, Intel® 64 architecture

`-[no-]fnsplit`: IA-64 architecture

Syntax

Linux:

`-fnsplit`

`-no-fnsplit`

Mac OS X:

`None`

Windows:

`/Qfnsplit`

`/Qfnsplit-`

Arguments

None

Default

`-no-fnsplit` or `/Qfnsplit-`	Function splitting is not enabled unless `-prof-use` (Linux) or `/Qprof-use` (Windows) is also specified.

Description

This option enables function splitting if `-prof-use` (Linux) or `/Qprof-use` (Windows) is also specified. Otherwise, this option has no effect.

It is enabled automatically if you specify `-prof-use` or `/Qprof-use`. If you do not specify one of those options, the default is `-no-fnsplit` (Linux) or `/Qfnsplit-` (Windows), which disables function splitting but leaves function grouping enabled.

To disable function splitting when you use `-prof-use` or `/Qprof-use`, specify `-no-fnsplit` or `/Qfnsplit-`.

Alternate Options

None

See Also

-
-
- Profile-Guided Optimization (PGO) Quick Reference
- Profile an Application

fp-port, Qfp-port

Rounds floating-point results after floating-point operations.

IDE Equivalent

Windows: **Floating-Point > Round Floating-Point Results**

Linux: None

Mac OS X: **Floating-Point > Round Floating-Point Results**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-fp-port
-no-fp-port
```

Windows:

```
/Qfp-port
/Qfp-port-
```

Arguments

None

Default

`-no-fp-port` or `/Qfp-port-`	The default rounding behavior depends on the compiler's code generation decisions and the precision parameters of the operating system.

Description

This option rounds floating-point results after floating-point operations. Rounding to user-specified precision occurs at assignments and type conversions. This has some impact on speed.

The default is to keep results of floating-point operations in higher precision. This provides better performance but less consistent floating-point results.

Alternate Options

None

fp-relaxed, Qfp-relaxed

Enables use of faster but slightly less accurate code sequences for math functions.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-fp-relaxed`

`-no-fp-relaxed`

Mac OS X:

`None`

Windows:

`/Qfp-relaxed`

`/Qfp-relaxed-`

Arguments

None

Default

`-no-fp-relaxed` or `/Qfp-relaxed-`	Default code sequences are used for math functions.

Description

This option enables use of faster but slightly less accurate code sequences for math functions, such as divide and sqrt. When compared to strict IEEE* precision, this option slightly reduces the accuracy of floating-point calculations performed by these functions, usually limited to the least significant digit.

This option also enables the performance of more aggressive floating-point transformations, which may affect accuracy.

Alternate Options

Linux: `-IPF-fp-relaxed` (this is a deprecated option)

Windows: `/QIPF-fp-relaxed` (this is a deprecated option)

See Also

-
-
- `fp-model, fp`

fp-speculation, Qfp-speculation

Tells the compiler the mode in which to speculate on floating-point operations.

IDE Equivalent

Windows: **Floating Point > Floating-Point Speculation**

Linux: None

Mac OS X: **Floating Point > Floating-Point Speculation**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-fp-speculation=`*mode*

Windows:

`/Qfp-speculation:`*mode*

Arguments

mode	Is the mode for floating-point operations. Possible values are:	
	`fast`	Tells the compiler to speculate on floating-point operations.
	`safe`	Tells the compiler to disable speculation if there is a possibility that the speculation may cause a floating-point exception.
	`strict`	Tells the compiler to disable speculation on floating-point operations.
	`off`	This is the same as specifying strict.

Default

`-fp-speculation=fast` or `/Qfp-speculation:fast`	The compiler speculates on floating-point operations. This is also the behavior when optimizations are enabled. However, if you specify no optimizations (`-O0` on Linux; `/Od` on Windows), the default is `-fp-speculation=safe` (Linux) or `/Qfp-speculation:safe` (Windows).

Description

This option tells the compiler the mode in which to speculate on floating-point operations.

Alternate Options

None

•
•

Floating-point Operations: Floating-point Options Quick Reference

fp-stack-check, Qfp-stack-check

Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.

IDE Equivalent

Windows: **Floating-Point > Check Floating-point Stack**

Linux: None

Mac OS X: **Floating-Point > Check Floating-point Stack**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-fp-stack-check
```

Windows:

```
/Qfp-stack-check
```

Arguments

None

Default

OFF	There is no checking to ensure that the floating-point (FP) stack is in the expected state.

Description

This option tells the compiler to generate extra code after every function call to ensure that the floating-point (FP) stack is in the expected state.

By default, there is no checking. So when the FP stack overflows, a NaN value is put into FP calculations and the program's results differ. Unfortunately, the overflow point can be far away from the point of the actual bug. This option places code that causes an access violation exception immediately after an incorrect call occurs, thus making it easier to locate these issues.

Alternate Options

None

•
•

Floating-point Operations:

- Checking the Floating-point Stack State

fpp, Qfpp

Runs the Fortran preprocessor on source files before compilation.

IDE Equivalent

Windows: **Preprocessor > Preprocess Source File**

Linux: None

Mac OS X: Preprocessor > Preprocess Source File

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`fpp[`*`n`*`]`

`fpp[="`*`option`*`"]`

`-nofpp`

Windows:

`/fpp[n]`

`/fpp[:"option"]`

`/nofpp`

`/Qfpp[n]`

`/Qfpp[:"option"]`

Arguments

n	Deprecated. Tells the compiler whether to run the preprocessor or not. Possible values are:
	`0` Tells the compiler not to run the preprocessor.
	`1, 2, or 3` Tells the compiler to run the preprocessor.
option	Is a Fortran preprocessor (fpp) option; for example, "-macro=no", which disables macro expansion. The quotes are required. For a list of fpp options, see *Fortran Preprocessor Options*.

Default

`nofpp`	The Fortran preprocessor is not run on files before compilation.

Description

This option runs the Fortran preprocessor on source files before they are compiled.

If the option is specified with no argument, the compiler runs the preprocessor.

If `0` is specified for *n*, it is equivalent to `nofpp`.Note that argument *n* is deprecated.

We recommend you use option `Qoption,fpp,"option"` to pass fpp options to the Fortran preprocessor.

Alternate Options

Linux and Mac OS X: `-cpp`

Windows: `/Qcpp`

-
- Fortran Preprocessor Options
- Qoption

ftz, Qftz

Flushes denormal results to zero.

IDE Equivalent

Windows: (IA-32 and IA-64 architectures): **Floating Point > Flush Denormal Results to Zero**

(Intel® 64 architecture): None

Linux: None

Mac OS X: **Floating Point > Flush Denormal Results to Zero**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-ftz
```

```
-no-ftz
```

Windows:

```
/Qftz
```

```
/Qftz-
```

Arguments

None

Default

Systems using IA-64 architecture: `-no-ftz` or `/Qftz-` Systems using IA-32 architecture and Intel® 64 architecture: `-ftz` or `/Qftz`	On systems using IA-64 architecture, the compiler lets results gradually underflow. On systems using IA-32 architecture and Intel® 64 architecture, denormal results are flushed to zero.

Description

This option flushes denormal results to zero when the application is in the gradual underflow mode. It may improve performance if the denormal values are not critical to your application's behavior.

This option sets or resets the FTZ and the DAZ hardware flags. If FTZ is ON, denormal results from floating-point calculations will be set to the value zero. If FTZ is OFF, denormal results remain as is. If DAZ is ON, denormal values used as input to floating-point instructions will be treated as zero. If DAZ is OFF, denormal instruction inputs remain as is. Systems using IA-64 architecture have FTZ but not DAZ. Systems using Intel® 64 architecture have both FTZ and DAZ. FTZ and DAZ are not supported on all IA-32 architectures.

When `-ftz` (Linux and Mac OS X) or `/Qftz` (Windows) is used in combination with an SSE-enabling option on systems using IA-32 architecture (for example, `xN` or `QxN`), the compiler will insert code in the main routine to set FTZ and DAZ. When `-ftz` or `/Qftz` is used without such an option, the compiler will insert code to conditionally set FTZ/DAZ based on a run-time processor check. `-no-ftz` (Linux and Mac OS X) or `/Qftz-` (Windows) will prevent the compiler from inserting any code that might set FTZ or DAZ.

This option only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in FTZ/DAZ mode.

Options `-fpe0` and `-fpe1` (Linux and Mac OS X) set `-ftz`. Options `/fpe:0` and `/fpe:1` (Windows) set `/Qftz`.

On systems using IA-64 architecture, optimization option `O3` sets `-ftz` and `/Qftz`; optimization option `O2` sets `-no-ftz` (Linux) and `/Qftz-` (Windows). On systems using IA-32 architecture and Intel® 64 architecture, every optimization option `O` level, except `O0`, sets `-ftz` and `/Qftz`.

If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by using `-no-ftz` or `/Qftz-` in the command line while still benefiting from the `O3` optimizations.

NOTE. Options `-ftz` and `/Qftz` are performance options. Setting these options does not guarantee that all denormals in a program are flushed to zero. They only cause denormals generated at run time to be flushed to zero.

Alternate Options

None

-
- `x, Qx`

Floating-point Operations: Using the -fpe or /fpe Compiler Option

global-hoist, Qglobal-hoist

Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-global-hoist
-no-global-hoist
```

Windows:

```
/Qglobal-hoist
/Qglobal-hoist-
```

Arguments

None

Default

`-global-hoist` or `/Qglobal-hoist`	Certain optimizations are enabled that can move memory loads.

Description

This option enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source. In most cases, these optimizations are safe and can improve performance.

The `-no-global-hoist` (Linux and Mac OS X) or `/Qglobal-hoist-` (Windows) option is useful for some applications, such as those that use shared or dynamically mapped memory, which can fail if a load is moved too early in the execution stream (for example, before the memory is mapped).

Alternate Options

None

QIA64-fr32

Disables use of high floating-point registers.

IDE Equivalent

Windows: **Floating Point > Disable Use of High Floating-Point Registers**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux and Mac OS X:

`None`

Windows:

`/QIA64-fr32`

Arguments

None

Default

OFF	Use of high floating-point registers is enabled.

Description

This option disables use of high floating-point registers.

Alternate Options

None

Qlfist

See rcd, Qrcd.

Qimsl

Tells the compiler to link to the IMSL Fortran Numerical Library*(IMSL* library).*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Qimsl`

Arguments

None

Default

OFF	The compiler does not link to the IMSL* library.

Description

This option tells the compiler to link to the IMSL* Fortran Numerical Library* (IMSL* library). This option is applicable for users of editions of the Intel® Fortran Compiler product that include the IMSL* libraries.

Alternate Options

None

inline-debug-info, Qinline-debug-info

Produces enhanced source position information for inlined code. This is a deprecated option.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-inline-debug-info
```

Windows:

```
/Qinline-debug-info
```

Arguments

None

Default

OFF	No enhanced source position information is produced for inlined code.

Description

This option produces enhanced source position information for inlined code. This leads to greater accuracy when reporting the source location of any instruction. It also provides enhanced debug information useful for function call traceback.

To use this option for debugging, you must also specify a debug enabling option, such as `-g` (Linux) or `/debug` (Windows).

Alternate Options

Linux and Mac OS X: `-debug inline-debug-info`

Windows: None

Qinline-dllimport

Determines whether dllimport functions are inlined.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Qinline-dllimport`

`/Qinline-dllimport-`

Arguments

None

Default

`/Qinline-dllimport`	The dllimport functions are inlined.

Description

This option determines whether dllimport functions are inlined. To disable dllimport functions from being inlined, specify `/Qinline-dllimport-`.

Alternate Options

None

inline-factor, Qinline-factor

Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-factor=`*n*

`-no-inline-factor`

Windows:

`/Qinline-factor=`*n*

`/Qinline-factor-`

Arguments

n	Is a positive integer specifying the percentage value. The default value is 100 (a factor of 1).

Default

`-no-inline-factor` or `/Qinline-factor-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the percentage multiplier that should be applied to all inlining options that define upper limits:

- `-inline-max-size` and `/Qinline-max-size`
- `-inline-max-total-size` and `/Qinline-max-total-size`
- `-inline-max-per-routine` and `/Qinline-max-per-routine`
- `-inline-max-per-compile` and `/Qinline-max-per-compile`

This option takes the default value for each of the above options and multiplies it by *n* divided by 100. For example, if 200 is specified, all inlining options that define upper limits are multiplied by a factor of 2. This option is useful if you do not want to individually increase each option limit.

If you specify `-no-inline-factor` (Linux and Mac OS X) or `/Qinline-factor-` (Windows), the following occurs:

- Every function is considered to be a small or medium function; there are no large functions.
- There is no limit to the size a routine may grow when inline expansion is performed.
- There is no limit to the number of times some routine may be inlined into a particular routine.
- There is no limit to the number of times inlining can be applied to a compilation unit.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase default limits, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

inline-forceinline, Qinline-forceinline

Specifies that an inline routine should be inlined whenever the compiler can do so.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-inline-forceinline
```

Windows:

```
/Qinline-forceinline
```

Default

OFF	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies that a inline routine should be inlined whenever the compiler can do so. This causes the routines marked with an inline keyword or directive to be treated as if they were "forceinline".

NOTE. Because C++ member functions whose definitions are included in the class declaration are considered inline functions by default, using this option will also make these member functions "forceinline" functions.

The "forceinline" condition can also be specified by using the directive cDEC$ ATTRIBUTES FORCEINLINE.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS) or `/Qopt-report` (Windows).

CAUTION. When you use this option to change the meaning of inline to "forceinline", the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`
- Developer Directed Inline Expansion of User Functions

inline-max-per-compile, Qinline-max-per-compile

Specifies the maximum number of times inlining may be applied to an entire compilation unit.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-per-compile=`*n*

`-no-inline-max-per-compile`

Windows:

`/Qinline-max-per-compile=`*n*

`/Qinline-max-per-compile-`

Arguments

n	Is a positive integer that specifies the number of times inlining may be applied.

Default

`-no-inline-max-per-compile` or `/Qinline-max-per-compile-`	The compiler uses default heuristics for inline routine expansion.

Description

This option the maximum number of times inlining may be applied to an entire compilation unit. It limits the number of times that inlining can be applied.

For compilations using Interprocedural Optimizations (IPO), the entire compilation is a compilation unit. For other compilations, a compilation unit is a file.

If you specify `-no-inline-max-per-compile` (Linux and Mac OS X) or `/Qinline-max-per-compile-` (Windows), there is no limit to the number of times inlining may be applied to a compilation unit.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

- Developer Directed Inline Expansion of User Functions
- Compiler Directed Inline Expansion of User Functions

inline-max-per-routine, Qinline-max-per-routine

Specifies the maximum number of times the inliner may inline into a particular routine.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-per-routine=`*n*

`-no-inline-max-per-routine`

Windows:

`/Qinline-max-per-routine=`*n*

`/Qinline-max-per-routine-`

Arguments

n	Is a positive integer that specifies the maximum number of times the inliner may inline into a particular routine.

Default

`-no-inline-max-per-routine` or `/Qinline-max-per-routine-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the maximum number of times the inliner may inline into a particular routine. It limits the number of times that inlining can be applied to any routine.

If you specify `-no-inline-max-per-routine` (Linux and Mac OS X) or `/Qinline-max-per-routine-` (Windows), there is no limit to the number of times some routine may be inlined into a particular routine.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

-
- `inline-factor`, `Qinline-factor`
- `opt-report`, `Qopt-report`
- Developer Directed Inline Expansion of User Functions
- Compiler Directed Inline Expansion of User Functions

inline-max-size, Qinline-max-size

Specifies the lower limit for the size of what the inliner considers to be a large routine.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-size=`*n*

`-no-inline-max-size`

Windows:

`/Qinline-max-size=`*n*

`/Qinline-max-size-`

Arguments

n	Is a positive integer that specifies the minimum size of what the inliner considers to be a large routine.

Default

`-no-inline-max-size` or `/Qinline-max-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the lower limit for the size of what the inliner considers to be a large routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be medium and large-size routines.

The inliner prefers to inline small routines. It has a preference against inlining large routines. So, any large routine is highly unlikely to be inlined.

If you specify `-no-inline-max-size` (Linux and Mac OS X) or `/Qinline-max-size-` (Windows), there are no large routines. Every routine is either a small or medium routine.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

See Also

-
-

inline-max-total-size, Qinline-max-total-size

Specifies how much larger a routine can normally grow when inline expansion is performed.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-max-total-size=`*n*

`-no-inline-max-total-size`

Windows:

`/Qinline-max-total-size=`*n*

`/Qinline-max-total-size-`

Arguments

n	Is a positive integer that specifies the permitted increase in the routine's size when inline expansion is performed.

Default

`-no-inline-max-total-size` or `/Qinline-max-total-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies how much larger a routine can normally grow when inline expansion is performed. It limits the potential size of the routine. For example, if 2000 is specified for *n*, the size of any routine will normally not increase by more than 2000.

If you specify `-no-inline-max-total-size` (Linux and Mac OS X) or `/Qinline-max-total-size-` (Windows), there is no limit to the size a routine may grow when inline expansion is performed.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

inline-min-size, Qinline-min-size

Specifies the upper limit for the size of what the inliner considers to be a small routine.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-inline-min-size=`*n*

`-no-inline-min-size`

Windows:

`/Qinline-min-size=`*n*

`/Qinline-min-size-`

Arguments

n	Is a positive integer that specifies the maximum size of what the inliner considers to be a small routine.

Default

`-no-inline-min-size` or `/Qinline-min-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the upper limit for the size of what the inliner considers to be a small routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be small and medium-size routines.

The inliner has a preference to inline small routines. So, when a routine is smaller than or equal to the specified size, it is very likely to be inlined.

If you specify `-no-inline-min-size` (Linux and Mac OS X) or `/Qinline-min-size-` (Windows), there is no limit to the size of small routines. Every routine is a small routine; there are no medium or large routines.

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

To see compiler values for important inlining limits, specify compiler option `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

CAUTION. When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Alternate Options

None

- Developer Directed Inline Expansion of User Functions
- Compiler Directed Inline Expansion of User Functions

Qinstall

Specifies the root directory where the compiler installation was performed.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Qinstall`*`dir`*

Windows:

`None`

Arguments

`dir`	Is the root directory where the installation was performed.

Default

OFF	The default root directory for compiler installation is searched for the compiler.

Description

This option specifies the root directory where the compiler installation was performed. It is useful if you want to use a different compiler or if you did not use the ifortvars shell script to set your environment variables.

Alternate Options

None

minstruction, Qinstruction

Determines whether MOVBE instructions are generated for Intel processors.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-minstruction=[no]movbe`

Windows:

`/Qinstruction:[no]movbe`

Arguments

None

Default

`-minstruction=nomovbe` or `/Qinstruction:nomovbe` The compiler does not generate MOVBE instructions for Intel® Atom™ processors.

Description

This option determines whether MOVBE instructions are generated for Intel processors. To use this option, you must also specify `-xSSE3_ATOM` (Linux and Mac OS X) or `/QxSSE3_ATOM` (Windows).

If `-minstruction=movbe` or `/Qinstruction:movbe` is specified, the following occurs:

- MOVBE instructions are generated that are specific to the Intel® Atom™ processor.
- The options are ON by default when `-xSSE3_ATOM` or `/QxSSE3_ATOM` is specified.
- Generated executables can only be run on Intel® Atom™ processors or processors that support Intel® Streaming SIMD Extensions 3 (Intel® SSE3) and MOVBE.

If -minstruction=nomovbe or /Qinstruction:nomovbe is specified, the following occurs:

- The compiler optimizes code for the Intel® Atom™ processor, but it does not generate MOVBE instructions.
- Generated executables can be run on non-Intel® Atom™ processors that support Intel® SSE3.

Alternate Options

None

See Also

-
-
- x, Qx

finstrument-functions, Qinstrument-functions

Determines whether routine entry and exit points are instrumented.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-finstrument-functions
-fno-instrument-functions
```

Windows:

```
/Qinstrument-functions
/Qinstrument-functions-
```

Arguments

None

Default

`-fno-instrument-functions` or `/Qinstrument-functions-`	Routine entry and exit points are not instrumented.

Description

This option determines whether routine entry and exit points are instrumented. It may increase execution time.

The following profiling functions are called with the address of the current routine and the address of where the routine was called (its "call site"):

- This function is called upon routine entry:
  - On IA-32 architecture and Intel® 64 architecture:

    ```
    void __cyg_profile_func_enter (void *this_fn,
    void *call_site);
    ```

  - On IA-64 architecture:

    ```
    void __cyg_profile_func_enter (void **this_fn,
    void *call_site);
    ```

- This function is called upon routine exit:
  - On IA-32 architecture and Intel® 64 architecture:

    ```
    void __cyg_profile_func_exit (void *this_fn,
    void *call_site);
    ```

  - On IA-64 architecture:

    ```
    void __cyg_profile_func_exit (void **this_fn,
    void *call_site);
    ```

On IA-64 architecture, the additional de-reference of the function pointer argument is required to obtain the routine entry point contained in the first word of the routine descriptor for indirect routine calls. The descriptor is documented in the Intel® Itanium® Software Conventions and Runtime Architecture Guide, section 8.4.2. You can find this design guide at web site http://www.intel.com.

These functions can be used to gather more information, such as profiling information or timing information. Note that it is the user's responsibility to provide these profiling functions.

If you specify `-finstrument-functions` (Linux and Mac OS X) or `/Qinstrument-functions` (Windows), routine inlining is disabled. If you specify `-fno-instrument-functions` or `/Qinstrument-functions-`, inlining is not disabled.

This option is provided for compatibility with gcc.

Alternate Options

None

ip, Qip

Determines whether additional interprocedural optimizations for single-file compilation are enabled.

IDE Equivalent

Windows: **Optimization > Interprocedural Optimization**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ip`

`-no-ip`

Windows:

`/Qip`

`/Qip-`

Arguments

None

Default

OFF	Some limited interprocedural optimizations occur, including inline function expansion for calls to functions defined within the current source file. These optimizations are a subset of full intra-file interprocedural optimizations. Note that this setting is not the same as `-no-ip` (Linux and Mac OS X) or `/Qip-` (Windows).

Description

This option determines whether additional interprocedural optimizations for single-file compilation are enabled.

Options `-ip` (Linux and Mac OS X) and `/Qip` (Windows) enable additional interprocedural optimizations for single-file compilation.

Options `-no-ip` (Linux and Mac OS X) and `/Qip-` (Windows) may not disable inlining. To ensure that inlining of user-defined functions is disabled, specify `-inline-level=0`or `-fno-inline` (Linux and Mac OS X), or specify `/Ob0` (Windows).

Alternate Options

None

See Also

-
-
- `finline-functions`

ip-no-inlining, Qip-no-inlining

Disables full and partial inlining enabled by interprocedural optimization options.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ip-no-inlining`

Windows:

`/Qip-no-inlining`

Arguments

None

Default

OFF	Inlining enabled by interprocedural optimization options is performed.

Description

This option disables full and partial inlining enabled by the following interprocedural optimization options:

- On Linux and Mac OS X systems: `-ip` or `-ipo`
- On Windows systems: `/Qip`, `/Qipo`, or `/Ob2`

It has no effect on other interprocedural optimizations.

On Windows systems, this option also has no effect on user-directed inlining specified by option `/Ob1`.

Alternate Options

None

ip-no-pinlining, Qip-no-pinlining

Disables partial inlining enabled by interprocedural optimization options.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-ip-no-pinlining`

Windows:

`/Qip-no-pinlining`

Arguments

None

Default

OFF	Inlining enabled by interprocedural optimization options is performed.

Description

This option disables partial inlining enabled by the following interprocedural optimization options:

- On Linux and Mac OS X systems: `-ip` or `-ipo`
- On Windows systems: `/Qip` or `/Qipo`

It has no effect on other interprocedural optimizations.

Alternate Options

None

IPF-flt-eval-method0, QIPF-flt-eval-method0

Tells the compiler to evaluate the expressions involving floating-point operands in the precision indicated by the variable types declared in the program. This is a deprecated option.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-IPF-flt-eval-method0`

Mac OS X:

`None`

Windows:

`/QIPF-flt-eval-method0`

Arguments

None

Default

OFF	Expressions involving floating-point operands are evaluated by default rules.

Description

This option tells the compiler to evaluate the expressions involving floating-point operands in the precision indicated by the variable types declared in the program.

By default, intermediate floating-point expressions are maintained in higher precision.

The recommended method to control the semantics of floating-point calculations is to use option `-fp-model` (Linux) or `/fp` (Windows).

Instead of using `-IPF-flt-eval-method0` (Linux) or `/QIPF-flt-eval-method0` (Windows), you can use `-fp-model source` (Linux) or `/fp:source` (Windows).

Alternate Options

None

See Also

-
-

- fp-model, fp

IPF-fltacc, QIPF-fltacc

Disables optimizations that affect floating-point accuracy. This is a deprecated option.

IDE Equivalent

Windows: **Floating Point > Floating-Point Accuracy**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux:

`-IPF-fltacc`

`-no-IPF-fltacc`

Mac OS X:

`None`

Windows:

`/QIPF-fltacc`

`/QIPF-fltacc-`

Arguments

None

Default

`-no-IPF-fltacc` or `/QIPF-fltacc-`	Optimizations are enabled that affect floating-point accuracy.

Description

This option disables optimizations that affect floating-point accuracy.

If the default setting is used, the compiler may apply optimizations that reduce floating-point accuracy.

You can use this option to improve floating-point accuracy, but at the cost of disabling some optimizations.

The recommended method to control the semantics of floating-point calculations is to use option `-fp-model` (Linux) or `/fp` (Windows).

Instead of using `-IPF-fltacc` (Linux) or `/QIPF-fltacc` (Windows), you can use `-fp-model precise` (Linux) or `/fp:precise` (Windows).

Instead of using `-no-IPF-fltacc` (Linux) or `/QIPF-fltacc-` (Windows), you can use `-fp-model fast` (Linux) or `/fp:fast` (Windows).

Alternate Options

None

See Also

-
-
- `fp-model, fp`

IPF-fma, QIPF-fma

See fma, Qfma.

IPF-fp-relaxed, QIPF-fp-relaxed

See fp-relaxed, Qfp-relaxed.

ipo, Qipo

Enables interprocedural optimization between files.

IDE Equivalent

Windows: **Optimization > Interprocedural Optimization**

General > Whole Program Optimization

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo[n]`

Windows:

`/Qipo[n]`

Arguments

n	Is an optional integer that specifies the number of object files the compiler should create. The integer must be greater than or equal to 0.

Default

OFF	Multifile interprocedural optimization is not enabled.

Description

This option enables interprocedural optimization between files. This is also called multifile interprocedural optimization (multifile IPO) or Whole Program Optimization (WPO).

When you specify this option, the compiler performs inline function expansion for calls to functions defined in separate files.

You cannot specify the names for the files that are created.

If *n* is 0, the compiler decides whether to create one or more object files based on an estimate of the size of the application. It generates one object file for small applications, and two or more object files for large applications.

If *n* is greater than 0, the compiler generates *n* object files, unless *n* exceeds the number of source files (*m*), in which case the compiler generates only *m* object files.

If you do not specify *n*, the default is 0.

Alternate Options

None

•
•

Optimizing Applications:

Interprocedural Optimization (IPO) Quick Reference

Interprocedural Optimization (IPO) Overview

Using IPO

ipo-c, Qipo-c

Tells the compiler to optimize across multiple files and generate a single object file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo-c`

Windows:

`/Qipo-c`

Arguments

None

Default

OFF	The compiler does not generate a multifile object file.

Description

This option tells the compiler to optimize across multiple files and generate a single object file (named ipo_out.o on Linux and Mac OS X systems; ipo_out.obj on Windows systems).

It performs the same optimizations as `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows), but compilation stops before the final link stage, leaving an optimized object file that can be used in further link steps.

Alternate Options

None

See Also

-
-
- `ipo`, `Qipo`

ipo-jobs, Qipo-jobs

Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo-jobs`*n*

Windows:

`/Qipo-jobs:`*n*

Arguments

n	Is the number of commands (jobs) to run simultaneously. The number must be greater than or equal to 1.

Default

`-ipo-jobs1` or `/Qipo-jobs:1`	One command (job) is executed in an interprocedural optimization parallel build.

Description

This option specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO). It should only be used if the link-time compilation is generating more than one object. In this case, each object is generated by a separate compilation, which can be done in parallel.

This option can be affected by the following compiler options:

- `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows) when applications are large enough that the compiler decides to generate multiple object files.
- `-ipo`*n* (Linux and Mac OS X) or `/Qipo`*n* (Windows) when *n* is greater than 1.
- `-ipo-separate` (Linux) or `/Qipo-separate` (Windows)

CAUTION. Be careful when using this option. On a multi-processor system with lots of memory, it can speed application build time. However, if *n* is greater than the number of processors, or if there is not enough memory to avoid thrashing, this option can increase application build time.

Alternate Options

None

See Also

-
-
- `ipo`, `Qipo`
- `ipo-separate`, `Qipo-separate`

ipo-S, Qipo-S

Tells the compiler to optimize across multiple files and generate a single assembly file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ipo-S`

Windows:

`/Qipo-S`

Arguments

None

Default

OFF	The compiler does not generate a multifile assembly file.

Description

This option tells the compiler to optimize across multiple files and generate a single assembly file (named ipo_out.s on Linux and Mac OS X systems; ipo_out.asm on Windows systems).

It performs the same optimizations as `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows), but compilation stops before the final link stage, leaving an optimized assembly file that can be used in further link steps.

Alternate Options

None

See Also

•

-
- ipo, Qipo

ipo-separate, Qipo-separate

Tells the compiler to generate one object file for every source file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-ipo-separate`

Mac OS X:

`None`

Windows:

`/Qipo-separate`

Arguments

None

Default

OFF	The compiler decides whether to create one or more object files.

Description

This option tells the compiler to generate one object file for every source file. It overrides any `-ipo` (Linux) or `/Qipo` (Windows) specification.

Alternate Options

None

See Also

-
-
- ipo, Qipo

ivdep-parallel, Qivdep-parallel

Tells the compiler that there is no loop-carried memory dependency in the loop following an IVDEP directive.

IDE Equivalent

Windows: **Optimization > IVDEP Directive Memory Dependency**

Linux: None

Mac OS X: None

Architectures

IA-64 architecture

Syntax

Linux:

`-ivdep-parallel`

Mac OS X:

`None`

Windows:

`/Qivdep-parallel`

Arguments

None

Default

OFF	There may be loop-carried memory dependency in a loop that follows an IVDEP directive.

Description

This option tells the compiler that there is no loop-carried memory dependency in the loop following an IVDEP There may be loop-carried memory dependency in a loop that follows an IVDEP directive.
This has the same effect as specifying the IVDEP:LOOP directive.

Alternate Options

None

See Also

•
•

Optimizing Applications: Absence of Loop-carried Memory Dependency with IVDEP Directive

fkeep-static-consts, Qkeep-static-consts

Tells the compiler to preserve allocation of variables that are not referenced in the source.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-fkeep-static-consts
-fno-keep-static-consts
```

Windows:

```
/Qkeep-static-consts
/Qkeep-static-consts-
```

Arguments

None

Default

`-fno-keep-static-consts` or `/Qkeep-static-consts-`	If a variable is never referenced in a routine, the variable is discarded unless optimizations are disabled by option `-O0` (Linux and Mac OS X) or `/Od` (Windows).

Description

This option tells the compiler to preserve allocation of variables that are not referenced in the source.

The negated form can be useful when optimizations are enabled to reduce the memory usage of static data.

Alternate Options

None

Qlocation

Specifies the directory for supporting tools.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Qlocation,`*`string`*`,`*`dir`*

Windows:

`/Qlocation,`*`string`*`,`*`dir`*

Arguments

`string`	Is the name of the tool.
`dir`	Is the directory (path) where the tool is located.

Default

OFF	The compiler looks for tools in a default area.

Description

This option specifies the directory for supporting tools.

string can be any of the following:

- f - Indicates the Intel Fortran compiler.
- fpp (or cpp) - Indicates the Intel Fortran preprocessor.
- asm - Indicates the assembler.
- link - Indicates the linker.
- prof - Indicates the profiler.
- On Windows systems, the following is also available:
  - masm - Indicates the Microsoft assembler.
- On Linux and Mac OS X systems, the following are also available:
  - as - Indicates the assembler.
  - gas - Indicates the GNU assembler.
  - ld - Indicates the loader.
  - gld - Indicates the GNU loader.
  - lib - Indicates an additional library.
  - crt - Indicates the crt%.o files linked into executables to contain the place to start execution.

Alternate Options

None

Example

The following command provides the path for the fpp tool:

```
ifort -Qlocation,fpp,/usr/preproc myprog.f
```

See Also

-
- `Qoption`

lowercase, Qlowercase

See names.

map-opts, Qmap-opts

Maps one or more compiler options to their equivalent on a different operating system.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-map-opts`

Mac OS X:

`None`

Windows:

`/Qmap-opts`

Arguments

None

Default

OFF	No platform mappings are performed.

Description

This option maps one or more compiler options to their equivalent on a different operating system. The result is output to `stdout`.

On Windows systems, the options you provide are presumed to be Windows options, so the options that are output to `stdout` will be Linux equivalents.
On Linux systems, the options you provide are presumed to be Linux options, so the options that are output to `stdout` will be Windows equivalents.

The tool can be invoked from the compiler command line or it can be used directly.

No compilation is performed when the option mapping tool is used.

This option is useful if you have both compilers and want to convert scripts or makefiles.

NOTE. Compiler options are mapped to their equivalent on the architecture you are using.
For example, if you are using a processor with IA-32 architecture, you will only see equivalent options that are available on processors with IA-32 architecture.

Alternate Options

None

Example

The following command line invokes the option mapping tool, which maps the Linux options to Windows-based options, and then outputs the results to `stdout`:

```
ifort -map-opts -xP -O2
```

The following command line invokes the option mapping tool, which maps the Windows options to Linux-based options, and then outputs the results to `stdout`:

```
ifort /Qmap-opts /QxP /O2
```

Building Applications: Using the Option Mapping Tool

mkl, Qmkl

Tells the compiler to link to certain parts of the Intel® Math Kernel Library (Intel® MKL).

IDE Equivalent

Windows: **Libraries > Use Intel(R) Math Kernel Library**

Linux: None

Mac OS X: **Libraries > Use Inte(R)l Math Kernel Library**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-mkl[=`*`lib`*`]`

Windows:

`/Qmkl[:`*`lib`*`]`

Arguments

`lib`

Indicates the part of the library that the compiler should link to. Possible values are:

`parallel`
Tells the compiler to link using the threaded part of the Intel® MKL. This is the default if the option is specified with no *`lib`*.

`sequential`
Tells the compiler to link using the non-threaded part of the Intel® MKL.

`cluster`
Tells the compiler to link using the cluster part and the sequential part of the Intel® MKL.

Default

OFF
The compiler does not link to the Intel® MKL.

Description

This option tells the compiler to link to certain parts of the Intel® Math Kernel Library (Intel® MKL).

Alternate Options

None

no-bss-init, Qnobss-init

Tells the compiler to place in the DATA section any variables explicitly initialized with zeros.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-no-bss-init
```

Windows:

```
/Qnobss-init
```

Arguments

None

Default

OFF	Variables explicitly initialized with zeros are placed in the BSS section.

Description

This option tells the compiler to place in the DATA section any variables explicitly initialized with zeros.

Alternate Options

Linux and Mac OS X: `-nobss-init` (this is a deprecated option)

Windows: None

onetrip, Qonetrip

Tells the compiler to follow the FORTRAN 66 Standard and execute DO loops at least once.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-onetrip`

Windows:

`/Qonetrip`

Arguments

None

Default

OFF	The compiler applies the current Fortran Standard semantics, which allows zero-trip DO loops.

Description

This option tells the compiler to follow the FORTRAN 66 Standard and execute DO loops at least once.

Alternate Options

Linux and Mac OS X: -1

Windows: /1

openmp, Qopenmp

Enables the parallelizer to generate multi-threaded code based on the OpenMP directives.*

IDE Equivalent

Windows: **Language > Process OpenMP Directives**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp`

Windows:

`/Qopenmp`

Arguments

None

Default

OFF	No OpenMP multi-threaded code is generated by the compiler.

Description

This option enables the parallelizer to generate multi-threaded code based on the OpenMP* directives. The code can be executed in parallel on both uniprocessor and multiprocessor systems.

If you use this option, multithreaded libraries are used, but option `fpp` is not automatically invoked.

This option sets option `automatic`.

This option works with any optimization level. Specifying no optimization (`-O0` on Linux or `/Od` on Windows) helps to debug OpenMP applications.

NOTE. On Mac OS X systems, when you enable OpenMP*, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode or an error will be displayed.

Alternate Options

None

See Also

-
-
- `openmp-stubs`, `Qopenmp-stubs`

openmp-lib, Qopenmp-lib

Lets you specify an OpenMP run-time library to use for linking.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-openmp-lib` *`type`*

Mac OS X:

`None`

Windows:

`/Qopenmp-lib:`*`type`*

Arguments

`type`	Specifies the type of library to use; it implies compatibility levels. Possible values are:

`legacy`	Tells the compiler to use the legacy OpenMP* run-time library (libguide). This setting does not provide compatibility with object files created using other compilers. This is a deprecated option.
`compat`	Tells the compiler to use the compatibility OpenMP* run-time library (libiomp). This setting provides compatibility with object files created using Microsoft* and GNU* compilers.

Default

`-openmp-lib compat` or `/Qopenmp-lib:compat`	The compiler uses the compatibility OpenMP* run-time library (libiomp).

Description

This option lets you specify an OpenMP* run-time library to use for linking.

The legacy OpenMP run-time library is not compatible with object files created using OpenMP run-time libraries supported in other compilers.

The compatibility OpenMP run-time library is compatible with object files created using the Microsoft* OpenMP run-time library (vcomp) and GNU OpenMP run-time library (libgomp).

To use the compatibility OpenMP run-time library, compile and link your application using the `-openmp-lib compat` (Linux) or `/Qopenmp-lib:compat` (Windows) option. To use this option, you must also specify one of the following compiler options:

- Linux OS: `-openmp`, `-openmp-profile`, or `-openmp-stubs`
- Windows OS: `/Qopenmp`, `/Qopenmp-profile`, or `/Qopenmp-stubs`

On Windows* systems, the compatibility OpenMP* run-time library lets you combine OpenMP* object files compiled with the Microsoft* C/C++ compiler with OpenMP* object files compiled with the Intel C/C++ or Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

On Linux* systems, the compatibility Intel OpenMP* run-time library lets you combine OpenMP* object files compiled with the GNU* gcc or gfortran compilers with similar OpenMP* object files compiled with the Intel C/C++ or Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

You cannot link object files generated by the Intel® Fortran compiler to object files compiled by the GNU Fortran compiler, regardless of the presence or absence of the `-openmp` (Linux) or `/Qopenmp` (Windows) compiler option. This is because the Fortran run-time libraries are incompatible.

NOTE. The compatibility OpenMP run-time library is not compatible with object files created using versions of the Intel compiler earlier than 10.0.

Alternate Options

None

See Also

-
-
- `openmp`, `Qopenmp`
- `openmp-stubs`, `Qopenmp-stubs`
- `openmp-profile`, `Qopenmp-profile`

openmp-link, Qopenmp-link

Controls whether the compiler links to static or dynamic OpenMP run-time libraries.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp-link` *`library`*

Windows:

`/Qopenmp-link:`*`library`*

Arguments

library	Specifies the OpenMP library to use. Possible values are:	
	`static`	Tells the compiler to link to static OpenMP run-time libraries.
	`dynamic`	Tells the compiler to link to dynamic OpenMP run-time libraries.

Default

`-openmp-link dynamic` or `/Qopenmp-link:dynamic`	The compiler links to dynamic OpenMP run-time libraries. However, if option `static` is specified, the compiler links to static OpenMP run-time libraries.

Description

This option controls whether the compiler links to static or dynamic OpenMP run-time libraries.

To link to the static OpenMP run-time library (RTL) and create a purely static executable, you must specify `-openmp-link static` (Linux and Mac OS X) or `/Qopenmp-link:static` (Windows). However, we strongly recommend you use the default setting, `-openmp-link dynamic` (Linux and Mac OS X) or `/Qopenmp-link:dynamic` (Windows).

NOTE. Compiler options `-static-intel` and `-shared-intel` (Linux and Mac OS X) have no effect on which OpenMP run-time library is linked.

Alternate Options

None

openmp-profile, Qopenmp-profile

Enables analysis of OpenMP applications if Intel® Thread Profiler is installed.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-openmp-profile`

Mac OS X:

`None`

Windows:

`/Qopenmp-profile`

Arguments

None

Default

OFF	OpenMP applications are not analyzed.

Description

This option enables analysis of OpenMP* applications. To use this option, you must have previously installed Intel® Thread Profiler, which is one of the Intel® Threading Analysis Tools.

This option can adversely affect performance because of the additional profiling and error checking invoked to enable compatibility with the threading tools. Do not use this option unless you plan to use the Intel® Thread Profiler.

For more information about Intel® Thread Profiler, open the page associated with threading tools at Intel® Software Development Products.

Alternate Options

None

openmp-report, Qopenmp-report

Controls the OpenMP parallelizer's level of diagnostic messages.*

IDE Equivalent

Windows: **Compilation Diagnostics > OpenMP Diagnostic Level**

Linux: None

Mac OS X: **Compiler Diagnostics > OpenMP Report**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp-report[n]`

Windows:

`/Qopenmp-report[n]`

Arguments

n	Is the level of diagnostic messages to display. Possible values are:	
	`0`	No diagnostic messages are displayed.
	`1`	Diagnostic messages are displayed indicating loops, regions, and sections successfully parallelized.
	`2`	The same diagnostic messages are displayed as specified by openmp_report1 plus diagnostic messages indicating successful handling of MASTER constructs, SINGLE constructs, CRITICAL constructs, ORDERED constructs, ATOMIC directives, and so forth.

Default

`-openmp-report1` or `/Qopenmp-report1`	If you do not specify *n*, the compiler displays diagnostic messages indicating loops, regions, and sections successfully parallelized. If you do not specify the option on the command line, the default is to display no messages.

Description

This option controls the OpenMP* parallelizer's level of diagnostic messages. To use this option, you must also specify `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows).

If this option is specified on the command line, the report is sent to `stdout`.

On Windows systems, if this option is specified from within the IDE, the report is included in the build log if the Generate Build Logs option is selected.

Alternate Options

None

See Also

-
-
- `openmp`, `Qopenmp`

Optimizing Applications:

Using Parallelism

OpenMP* Report

openmp-stubs, Qopenmp-stubs

Enables compilation of OpenMP programs in sequential mode.

IDE Equivalent

Windows: **Language > Process OpenMP Directives**

Linux: None

Mac OS X: **Language > Process OpenMP Directives**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-openmp-stubs`

Windows:

`/Qopenmp-stubs`

Arguments

None

Default

OFF	The library of OpenMP function stubs is not linked.

Description

This option enables compilation of OpenMP programs in sequential mode. The OpenMP directives are ignored and a stub OpenMP library is linked.

Alternate Options

None

See Also

-
-
- `openmp`, `Qopenmp`

openmp-threadprivate, Qopenmp-threadprivate

Lets you specify an OpenMP threadprivate implementation.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-openmp-threadprivate` *type*

Mac OS X:

`None`

Windows:

`/Qopenmp-threadprivate:`*type*

Arguments

type	Specifies the type of threadprivate implementation. Possible values are:	
	`legacy`	Tells the compiler to use the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler. This setting does not provide compatibility with the implementation used by other compilers.
	`compat`	Tells the compiler to use the compatibility OpenMP* threadprivate implementation based on applying the thread-local attribute to each threadprivate variable. This setting provides compatibility with the implementation provided by the Microsoft* and GNU* compilers.

Default

`-openmp-threadprivate legacy` or `/Qopenmp-threadprivate:legacy`	The compiler uses the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler.

Description

This option lets you specify an OpenMP* threadprivate implementation.

The legacy OpenMP run-time library is not compatible with object files created using OpenMP run-time libraries supported in other compilers.

To use this option, you must also specify one of the following compiler options:

- Linux OS: `-openmp`, `-openmp-profile`, or `-openmp-stubs`
- Windows OS: `/Qopenmp`, `/Qopenmp-profile`, or `/Qopenmp-stubs`

The value specified for this option is independent of the value used for option `-openmp-lib` (Linux) or `/Qopenmp-lib` (Windows).

Alternate Options

None

opt-block-factor, Qopt-block-factor

Lets you specify a loop blocking factor.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-block-factor=`*n*

Windows:

`/Qopt-block-factor:`*n*

Arguments

n	Is the blocking factor. It must be an integer. The compiler may ignore the blocking factor if the value is 0 or 1.

Default

OFF	The compiler uses default heuristics for loop blocking.

Description

This option lets you specify a loop blocking factor.

Alternate Options

None

opt-jump-tables, Qopt-jump-tables

Enables or disables generation of jump tables for switch statements.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-jump-tables=`*`keyword`*

`-no-opt-jump-tables`

Windows:

`/Qopt-jump-tables:`*`keyword`*

`/Qopt-jump-tables-`

Arguments

`keyword`	Is the instruction for generating jump tables. Possible values are:	
	`never`	Tells the compiler to never generate jump tables. All switch statements are implemented as chains of if-then-elses.

	This is the same as specifying `-no-opt-jump-tables` (Linux and Mac OS) or `/Qopt-jump-tables-` (Windows).
`default`	The compiler uses default heuristics to determine when to generate jump tables.
`large`	Tells the compiler to generate jump tables up to a certain pre-defined size (64K entries).
`n`	Must be an integer. Tells the compiler to generate jump tables up to *n* entries in size.

Default

`-opt-jump-tables=default` or `/Qopt-jump-tables:default`	The compiler uses default heuristics to determine when to generate jump tables for switch statements.

Description

This option enables or disables generation of jump tables for switch statements. When the option is enabled, it may improve performance for programs with large switch statements.

Alternate Options

None

opt-loadpair, Qopt-loadpair

Enables or disables loadpair optimization.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-loadpair`

`-no-opt-loadpair`

Mac OS X:

`None`

Windows:

`/Qopt-loadpair`

`/Qopt-loadpair-`

Arguments

None

Default

`-no-opt-loadpair` or `/Qopt-loadpair-`	Loadpair optimization is disabled unless option `O3` is specified.

Description

This option enables or disables loadpair optimization.

When `-O3` is specified on IA-64 architecture, loadpair optimization is enabled by default. To disable loadpair generation, specify `-no-opt-loadpair` (Linux) or `/Qopt-loadpair-` (Windows).

Alternate Options

None

opt-mem-bandwidth, Qopt-mem-bandwidth

Enables performance tuning and heuristics that control memory bandwidth use among processors.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-mem-bandwidth`*n*

Mac OS X:

`None`

Windows:

`/Qopt-mem-bandwidth`*n*

Arguments

n Is the level of optimizing for memory bandwidth usage. Possible values are:

`0`	Enables a set of performance tuning and heuristics in compiler optimizations that is optimal for serial code.
`1`	Enables a set of performance tuning and heuristics in compiler optimizations for multithreaded code generated by the compiler.
`2`	Enables a set of performance tuning and heuristics in compiler optimizations for parallel code such as Windows Threads, pthreads, and MPI code, besides multithreaded code generated by the compiler.

Default

`-opt-mem-bandwidth0` or `/Qopt-mem-bandwidth0` For serial (non-parallel) compilation, a set of performance tuning and heuristics in compiler optimizations is enabled that is optimal for serial code.

`-opt-mem-bandwidth1` or `/Qopt-mem-bandwidth1`	If you specify compiler option `-parallel` (Linux) or `/Qparallel` (Windows), or `-openmp` (Linux) or `/Qopenmp` (Windows), a set of performance tuning and heuristics in compiler optimizations for multithreaded code generated by the compiler is enabled.

Description

This option enables performance tuning and heuristics that control memory bandwidth use among processors. It allows the compiler to be less aggressive with optimizations that might consume more bandwidth, so that the bandwidth can be well-shared among multiple processors for a parallel program.

For values of *n* greater than 0, the option tells the compiler to enable a set of performance tuning and heuristics in compiler optimizations such as prefetching, privatization, aggressive code motion, and so forth, for reducing memory bandwidth pressure and balancing memory bandwidth traffic among threads.

This option can improve performance for threaded or parallel applications on multiprocessors or multicore processors, especially when the applications are bounded by memory bandwidth.

Alternate Options

None

See Also

-
-
- `parallel`, `Qparallel`
- `openmp`, `Qopenmp`

opt-mod-versioning, Qopt-mod-versioning

Enables or disables versioning of modulo operations for certain types of operands.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-mod-versioning`

`-no-opt-mod-versioning`

Mac OS X:

`None`

Windows:

`/Qopt-mod-versioning`

`/Qopt-mod-versioning-`

Arguments

None

Default

`-no-opt-mod-versioning` Versioning of modulo operations is disabled.
or `/Qopt-mod-versioning-`

Description

This option enables or disables versioning of modulo operations for certain types of operands. It is used for optimization tuning.

Versioning of modulo operations may improve performance for x mod y when modulus y is a power of 2.

Alternate Options

None

opt-multi-version-aggressive, Qopt-multi-version-aggressive

Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-opt-multi-version-aggressive`

`-no-opt-multi-version-aggressive`

Windows:

`/Qopt-multi-version-aggressive`

`/Qopt-multi-version-aggressive-`

Arguments

None

Default

`-no-opt-multi-version-aggressive` or `/Qopt-multi-version-aggressive-`	The compiler uses default heuristics when checking for pointer aliasing and scalar replacement.

Description

This option tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement. This option may improve performance.

Alternate Options

None

opt-prefetch, Qopt-prefetch

Enables or disables prefetch insertion optimization.

IDE Equivalent

Windows: **Optimization > Prefetch Insertion**

Linux: None

Mac OS X: **Optimization > Enable Prefetch Insertion**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-prefetch[=n]`

`-no-opt-prefetch`

Windows:

`/Qopt-prefetch[:n]`

`/Qopt-prefetch-`

Arguments

n	Is the level of detail in the report. Possible values are:	
	`0`	Disables software prefetching. This is the same as specifying `-no-opt-prefetch` (Linux and Mac OS X) or `/Qopt-prefetch-` (Windows).
	`1` to `4`	Enables different levels of software prefetching. If you do not specify a value for *n*, the default is `2` on IA-32 and Intel® 64 architecture; the default is `3` on IA-64 architecture. Use lower values to reduce the amount of prefetching.

Default

IA-64 architecture: `-opt-prefetch` or `/Qopt-prefetch`	On IA-64 architecture, prefetch insertion optimization is enabled.
IA-32 architecture and Intel® 64 architecture: `-no-opt-prefetch` or `/Qopt-prefetch-`	On IA-32 architecture and Intel® 64 architecture, prefetch insertion optimization is disabled.

Description

This option enables or disables prefetch insertion optimization. The goal of prefetching is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache.

On IA-64 architecture, this option is enabled by default if you specify option `O1` or higher. To disable prefetching at these optimization levels, specify `-no-opt-prefetch` (Linux and Mac OS X) or `/Qopt-prefetch-` (Windows).

On IA-32 architecture and Intel® 64 architecture, this option enables prefetching when higher optimization levels are specified.

Alternate Options

Linux and Mac OS X: `-prefetch` (this is a deprecated option)

Windows: `/Qprefetch` (this is a deprecated option)

opt-prefetch-initial-values, Qopt-prefetch-initial-values

Enables or disables prefetches that are issued before a loop is entered.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

```
-opt-prefetch-initial-values
-no-opt-prefetch-initial-values
```

Mac OS X:

```
None
```

Windows:

```
/Qopt-prefetch-initial-values
/Qopt-prefetch-initial-values-
```

Arguments

None

Default

`-opt-prefetch-initial-values` or `/Qopt-prefetch-initial-values` Prefetches are issued before a loop is entered.

Description

This option enables or disables prefetches that are issued before a loop is entered. These prefetches target the initial iterations of the loop.

When `-O1` or higher is specified on IA-64 architecture, prefetches are issued before a loop is entered. To disable these prefetches, specify `-no-opt-prefetch-initial-values` (Linux) or `/Qopt-prefetch-initial-values-` (Windows).

Alternate Options

None

opt-prefetch-issue-excl-hint, Qopt-prefetch-issue-excl-hint

Determines whether the compiler issues prefetches for stores with exclusive hint.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-prefetch-issue-excl-hint`

`-no-opt-prefetch-issue-excl-hint`

Mac OS X:

None

Windows:

/Qopt-prefetch-issue-excl-hint

/Qopt-prefetch-issue-excl-hint-

Arguments

None

Default

-no-opt-prefetch-issue-excl-hint or /Qopt-prefetch-issue-excl-hint-	The compiler does not issue prefetches for stores with exclusive hint.

Description

This option determines whether the compiler issues prefetches for stores with exclusive hint. If option -opt-prefetch-issue-excl-hint (Linux) or /Qopt-prefetch-issue-excl-hint (Windows) is specified, the prefetches will be issued if the compiler determines it is beneficial to do so.

When prefetches are issued for stores with exclusive-hint, the cache-line is in "exclusive-mode". This saves on cache-coherence traffic when other processors try to access the same cache-line. This feature can improve performance tuning.

Alternate Options

None

opt-prefetch-next-iteration, Qopt-prefetch-next-iteration

Enables or disables prefetches for a memory access in the next iteration of a loop.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux:

`-opt-prefetch-next-iteration`

`-no-opt-prefetch-next-iteration`

Mac OS X:

`None`

Windows:

`/Qopt-prefetch-next-iteration`

`/Qopt-prefetch-next-iteration-`

Arguments

None

Default

`-opt-prefetch-next-iteration` or `/Qopt-prefetch-next-iteration`	Prefetches are issued for a memory access in the next iteration of a loop.

Description

This option enables or disables prefetches for a memory access in the next iteration of a loop. It is typically used in a pointer-chasing loop.

When `-O1` or higher is specified on IA-64 architecture, prefetches are issued for a memory access in the next iteration of a loop. To disable these prefetches, specify `-no-opt-prefetch-next-iteration` (Linux) or `/Qopt-prefetch-next-iteration-` (Windows).

Alternate Options

None

opt-ra-region-strategy, Qopt-ra-region-strategy

Selects the method that the register allocator uses to partition each routine into regions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-opt-ra-region-strategy[=`*keyword*`]`

Windows:

`/Qopt-ra-region-strategy[:`*keyword*`]`

Arguments

keyword	Is the method used for partitioning. Possible values are:	
	`routine`	Creates a single region for each routine.
	`block`	Partitions each routine into one region per basic block.
	`trace`	Partitions each routine into one region per trace.
	`region`	Partitions each routine into one region per loop.
	`default`	The compiler determines which method is used for partitioning.

Default

`-opt-ra-region-strategy=default` or `/Qopt-ra-region-strategy:default`	The compiler determines which method is used for partitioning. This is also the default if `keyword` is not specified.

Description

This option selects the method that the register allocator uses to partition each routine into regions.

When setting `default` is in effect, the compiler attempts to optimize the tradeoff between compile-time performance and generated code performance.

This option is only relevant when optimizations are enabled (`O1` or higher).

Alternate Options

None

See Also

-
-
- `O`

opt-report, Qopt-report

Tells the compiler to generate an optimization report to stderr.

IDE Equivalent

Windows: Diagnostics > Optimization Diagnostics Level

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report [n]`

Windows:

`/Qopt-report[:n]`

Arguments

n	Is the level of detail in the report. On Linux OS and Mac OS X systems, a space must appear before the *n*. Possible values are:
	`0` Tells the compiler to generate no optimization report.
	`1` Tells the compiler to generate a report with the minimum level of detail.
	`2` Tells the compiler to generate a report with the medium level of detail.
	`3` Tells the compiler to generate a report with the maximum level of detail.

Default

`-opt-report 2` or `/Qopt-report:2`	If you do not specify *n*, the compiler generates a report with medium detail. If you do not specify the option on the command line, the compiler does not generate an optimization report.

Description

This option tells the compiler to generate an optimization report to `stderr`.

Alternate Options

None

See Also

-
-
- `opt-report-file`, `Qopt-report-file`

Optimizing Applications: Optimizer Report Generation

opt-report-file, Qopt-report-file

Specifies the name for an optimization report.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-file=`*`file`*

Windows:

`/Qopt-report-file:`*`file`*

Arguments

`file`	Is the name for the optimization report.

Default

OFF	No optimization report is generated.

Description

This option specifies the name for an optimization report. If you use this option, you do not have to specify `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`

Optimizing Applications: Optimizer Report Generation

opt-report-help, Qopt-report-help

Displays the optimizer phases available for report generation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-help`

Windows:

`/Qopt-report-help`

Arguments

None

Default

OFF	No optimization reports are generated.

Description

This option displays the optimizer phases available for report generation using `-opt-report-phase` (Linux and Mac OS X) or `/Qopt-report-phase` (Windows). No compilation is performed.

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`
- `opt-report-phase`, `Qopt-report-phase`

opt-report-phase, Qopt-report-phase

Specifies an optimizer phase to use when optimization reports are generated.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-phase=`*`phase`*

Windows:

`/Qopt-report-phase:`*`phase`*

Arguments

`phase` Is the phase to generate reports for. Some of the possible values are:

`ipo`	The Interprocedural Optimizer phase
`hlo`	The High Level Optimizer phase
`hpo`	The High Performance Optimizer phase
`ilo`	The Intermediate Language Scalar Optimizer phase
`ecg`	The Code Generator phase (Windows and Linux systems using IA-64 architecture only)
`ecg_swp`	The software pipelining component of the Code Generator phase (Windows and Linux systems using IA-64 architecture only)
`pgo`	The Profile Guided Optimization phase
`all`	All optimizer phases

Default

OFF	No optimization reports are generated.

Description

This option specifies an optimizer phase to use when optimization reports are generated. To use this option, you must also specify `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows).

This option can be used multiple times on the same command line to generate reports for multiple optimizer phases.

When one of the logical names for optimizer phases is specified for phase, all reports from that optimizer phase are generated.

To find all phase possibilities, use option `-opt-report-help` (Linux and Mac OS X) or `/Qopt-report-help` (Windows).

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`

opt-report-routine, Qopt-report-routine

Tells the compiler to generate reports on the routines containing specified text.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-opt-report-routine=`*`string`*

Windows:

`/Qopt-report-routine:`*`string`*

Arguments

`string`	Is the text (string) to look for.

Default

OFF	No optimization reports are generated.

Description

This option tells the compiler to generate reports on the routines containing specified text as part of their name.

Alternate Options

None

See Also

-
-
- `opt-report`, `Qopt-report`

opt-streaming-stores, Qopt-streaming-stores

Enables generation of streaming stores for optimization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-opt-streaming-stores` *keyword*

Windows:

`/Qopt-streaming-stores:`*keyword*

Arguments

keyword	Specifies whether streaming stores are generated. Possible values are:	
	`always`	Enables generation of streaming stores for optimization. The compiler optimizes under the assumption that the application is memory bound.
	`never`	Disables generation of streaming stores for optimization. Normal stores are performed.
	`auto`	Lets the compiler decide which instructions to use.

Default

`-opt-streaming-stores auto` or `/Qopt-streaming-stores:auto`	The compiler decides whether to use streaming stores or normal stores.

Description

This option enables generation of streaming stores for optimization. This method stores data with instructions that use a non-temporal buffer, which minimizes memory hierarchy pollution.

For this option to be effective, the compiler must be able to generate SSE2 (or higher) instructions. For more information, see compiler option `x` or `ax`.

This option may be useful for applications that can benefit from streaming stores.

Alternate Options

None

Optimizing Applications: Vectorization Support

opt-subscript-in-range, Qopt-subscript-in-range

Determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-opt-subscript-in-range
```

```
-no-opt-subscript-in-range
```

Windows:

```
/Qopt-subscript-in-range
```

```
/Qopt-subscript-in-range-
```

Arguments

None

Default

`-no-opt-subscript-in-range` or `/Qopt-subscript-in-range-`	The compiler assumes overflows in the intermediate computation of subscript expressions in loops.

Description

This option determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.

If you specify `-opt-subscript-in-range` (Linux and Mac OS X) or `/Qopt-subscript-in-range` (Windows), the compiler ignores any data type conversions used and it assumes no overflows in the intermediate computation of subscript expressions. This feature can enable more loop transformations.

Alternate Options

None

Example

The following shows an example where these options can be useful. m is declared as type integer(kind=8) (64-bits) and all other variables inside the subscript are declared as type integer(kind=4) (32-bits):

```
A[ i  + j  + ( n  + k) * m ]
```

Qoption

Passes options to a specified tool.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Qoption,`*`string`*`,`*`options`*

Windows:

`/Qoption,string,options`

Arguments

string	Is the name of the tool.
options	Are one or more comma-separated, valid options for the designated tool.

Default

OFF	No options are passed to tools.

Description

This option passes options to a specified tool.

If an argument contains a space or tab character, you must enclose the entire argument in quotation marks (" "). You must separate multiple arguments with commas.

string can be any of the following:

- fpp (or cpp) - Indicates the Intel Fortran preprocessor.
- asm - Indicates the assembler.
- link - Indicates the linker.
- prof - Indicates the profiler.
- On Windows systems, the following is also available:
  - masm - Indicates the Microsoft assembler.
- On Linux and Mac OS X systems, the following are also available:
  - as - Indicates the assembler.
  - gas - Indicates the GNU assembler.
  - ld - Indicates the loader.
  - gld - Indicates the GNU loader.
  - lib - Indicates an additional library.
  - crt - Indicates the crt%.o files linked into executables to contain the place to start execution.

Alternate Options

None

Example

On Linux and Mac OS X systems:

The following example directs the linker to link with an alternative library:

```
ifort -Qoption,link,-L.,-Lmylib prog1.f
```

The following example passes a compiler option to the assembler to generate a listing file:

```
ifort -Qoption,as,"-as=myprogram.lst" -use-asm myprogram.f90
```

On Windows systems:

The following example directs the linker to create a memory map when the compiler produces the executable file from the source being compiled:

```
ifort /Qoption,link,/map:prog1.map prog1.f
```

The following example passes a compiler option to the assembler:

```
ifort /Quse_asm /Qoption,masm,"/WX" myprogram.f90
```

qp

See p.

pad, Qpad

Enables the changing of the variable and array memory layout.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-pad`

`-nopad`

Windows:

`/Qpad`

`/Qpad-`

Arguments

None

Default

`-nopad` or `/Qpad-` Variable and array memory layout is performed by default methods.

Description

This option enables the changing of the variable and array memory layout.

This option is effectively not different from the `align` option when applied to structures and derived types. However, the scope of `pad` is greater because it applies also to common blocks, derived types, sequence types, and structures.

Alternate Options

None

See Also

-
-
- `align`

pad-source, Qpad-source

Specifies padding for fixed-form source records.

IDE Equivalent

Windows: **Language > Pad Fixed Form Source Lines**

Linux: None

Mac OS X: **Language > Pad Fixed Form Source Lines**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-pad-source`

`-nopad-source`

Windows:

`/pad-source`

`/nopad-source`

`/Qpad-source`

`/Qpad-source-`

Arguments

None

Default

`-nopad-source` or `/Qpad-source-` Fixed-form source records are not padded.

Description

This option specifies padding for fixed-form source records. It tells the compiler that fixed-form source lines shorter than the statement field width are to be padded with spaces to the end of the statement field. This affects the interpretation of character and Hollerith literals that are continued across source records.

The default value setting causes a warning message to be displayed if a character or Hollerith literal that ends before the statement field ends is continued onto the next source record. To suppress this warning message, specify option `-warn nousage` (Linux and Mac OS X) or `/warn:nousage` (Windows).

Specifying `pad-source` or `/Qpad-source` can prevent warning messages associated with option `-warn usage` (Linux and Mac OS X) or `/warn:usage` (Windows).

Alternate Options

None

See Also

-
-
- `warn`

Qpar-adjust-stack

Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Qpar-adjust-stack:`*n*

Arguments

n	Is the stack size (in bytes) for the fiber-based main thread. It must be a number equal to or greater than zero.

Default

`/Qpar-adjust-stack:0`	No adjustment is made to the main thread stack size.

Description

This option tells the compiler to generate code to adjust the stack size for a fiber-based main thread. This can reduce the stack size of threads.

For this option to be effective, you must also specify option `/Qparallel`.

Alternate Options

None

See Also

-
- `parallel`, `Qparallel`

par-affinity, Qpar-affinity

Specifies thread affinity.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-par-affinity=[`*`modifier`*`,...]`*`type`*`[,`*`permute`*`][,`*`offset`*`]`

Mac OS X:

`None`

Windows:

`/Qpar-affinity:[`*`modifier`*`,...]`*`type`*`[,`*`permute`*`][,`*`offset`*`]`

Arguments

`modifier`	Is one of the following values: `granularity={fine|thread|core}`, `[no]respect`, `[no]verbose`, `[no]warnings`, `proclist=proc_list`. The

	default is `granularity=core, respect, and noverbose`. For information on value `proclist`, see Thread Affinity Interface in *Optimizing Applications*.
type	Indicates the thread affinity. This argument is required and must be one of the following values: `compact`, `disabled`, `explicit`, `none`, `scatter`, `logical`, `physical`. The default is `none`. Values `logical` and `physical` are deprecated. Use `compact` and `scatter`, respectively, with no *permute* value.
permute	Is a positive integer. You cannot use this argument with *type* setting `explicit`, `none`, or `disabled`. The default is 0.
offset	Is a positive integer. You cannot use this argument with *type* setting `explicit`, `none`, or `disabled`. The default is 0.

Default

OFF	The thread affinity is determined by the run-time environment.

Description

This option specifies thread affinity, which binds threads to physical processing units. It has the same effect as environment variable KMP_AFFINITY.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- Linux* OS: You have specified option `-parallel` or `-openmp` (or both).

  Windows* OS: You have specified option `/Qparallel` or `/Qopenmp` (or both).
- You are compiling the main program.

Alternate Options

None

See Also

-
-

- Thread Affinity Interface

par-num-threads, Qpar-num-threads

Specifies the number of threads to use in a parallel region.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-num-threads=`*n*

Windows:

`/Qpar-num-threads:`*n*

Arguments

n	Is the number of threads to use. It must be a positive integer.

Default

OFF	The number of threads to use is determined by the run-time environment.

Description

This option specifies the number of threads to use in a parallel region. It has the same effect as environment variable OMP_NUM_THREADS.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- Linux* OS and Mac OS* X: You have specified option `-parallel` or `-openmp` (or both).

  Windows* OS: You have specified option `/Qparallel` or `/Qopenmp` (or both).

- You are compiling the main program.

Alternate Options

None

par-report, Qpar-report

Controls the diagnostic information reported by the auto-parallelizer.

IDE Equivalent

Windows: **Compilation Diagnostics > Auto-Parallelizer Diagnostic Level**

Linux: None

Mac OS X: **Diagnostics > Auto-Parallelizer Report**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-report[n]`

Windows:

`/Qpar-report[n]`

Arguments

n	Is a value denoting which diagnostic messages to report. Possible values are:
`0`	Tells the auto-parallelizer to report no diagnostic information.
`1`	Tells the auto-parallelizer to report diagnostic messages for loops successfully auto-parallelized. The compiler also issues a "LOOP AUTO-PARALLELIZED" message for parallel loops.

2	Tells the auto-parallelizer to report diagnostic messages for loops successfully and unsuccessfully auto-parallelized.
3	Tells the auto-parallelizer to report the same diagnostic messages specified by 2 plus additional information about any proven or assumed dependencies inhibiting auto-parallelization (reasons for not parallelizing).

Default

`-par-report1` or `/Qpar-report1`	If you do not specify *n*, the compiler displays diagnostic messages for loops successfully auto-parallelized. If you do not specify the option on the command line, the default is to display no messages.

Description

This option controls the diagnostic information reported by the auto-parallelizer (parallel optimizer). To use this option, you must also specify `-parallel` (Linux and Mac OS X) or `/Qparallel` (Windows).

If this option is specified on the command line, the report is sent to `stdout`.

On Windows systems, if this option is specified from within the IDE, the report is included in the build log if the Generate Build Logs option is selected.

Alternate Options

None

par-runtime-control, Qpar-runtime-control

Generates code to perform run-time checks for loops that have symbolic loop bounds.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-runtime-control`

`-no-par-runtime-control`

Windows:

`/Qpar-runtime-control`

`/Qpar-runtime-control-`

Arguments

None

Default

`-no-par-runtime-control` The compiler uses default heuristics when checking loops.
or `/Qpar-runtime-control-`

Description

This option generates code to perform run-time checks for loops that have symbolic loop bounds.

If the granularity of a loop is greater than the parallelization threshold, the loop will be executed in parallel.

If you do not specify this option, the compiler may not parallelize loops with symbolic loop bounds if the compile-time granularity estimation of a loop can not ensure it is beneficial to parallelize the loop.

Alternate Options

None

par-schedule, Qpar-schedule

Lets you specify a scheduling algorithm or a tuning method for loop iterations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-schedule-`*`keyword`*`[=`*`n`*`]`

Windows:

`/Qpar-schedule-`*`keyword`*`[[:]`*`n`*`]`

Arguments

keyword	Specifies the scheduling algorithm or tuning method. Possible values are:	
	`auto`	Lets the compiler or run-time system determine the scheduling algorithm.
	`static`	Divides iterations into contiguous pieces.
	`static-balanced`	Divides iterations into even-sized chunks.
	`static-steal`	Divides iterations into even-sized chunks, but allows threads to steal parts of chunks from neighboring threads.
	`dynamic`	Gets a set of iterations dynamically.
	`guided`	Specifies a minimum number of iterations.
	`guided-analytical`	Divides iterations by using exponential distribution or dynamic distribution.
	`runtime`	Defers the scheduling decision until run time.
n	Is the size of the chunk or the number of iterations for each chunk. This setting can only be specified for static, dynamic, and guided. For more information, see the descriptions of each keyword below.	

Default

static-balanced	Iterations are divided into even-sized chunks and the chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.

Description

This option lets you specify a scheduling algorithm or a tuning method for loop iterations. It specifies how iterations are to be divided among the threads of the team.

This option affects performance tuning and can provide better performance during auto-parallelization.

Option	Description
`-par-schedule-auto` or `/Qpar-schedule-auto`	Lets the compiler or run-time system determine the scheduling algorithm. Any possible mapping may occur for iterations to threads in the team.
`-par-schedule-static` or `/Qpar-schedule-static`	Divides iterations into contiguous pieces (chunks) of size *n*. The chunks are assigned to threads in the team in a round-robin fashion in the order of the thread number. Note that the last chunk to be assigned may have a smaller number of iterations. If no *n* is specified, the iteration space is divided into chunks that are approximately equal in size, and each thread is assigned at most one chunk.
`-par-schedule-static-balanced` or `/Qpar-schedule-static-balanced`	Divides iterations into even-sized chunks. The chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.
`-par-schedule-static-steal` or `/Qpar-schedule-static-steal`	Divides iterations into even-sized chunks, but when a thread completes its chunk, it can steal parts of chunks assigned to neighboring threads.

Option	Description
	Each thread keeps track of L and U, which represent the lower and upper bounds of its chunks respectively. Iterations are executed starting from the lower bound, and simultaneously, L is updated to represent the new lower bound.
`-par-schedule-dynamic` or `/Qpar-schedule-dynamic`	Can be used to get a set of iterations dynamically. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations. Each chunk contains *n* iterations, except for the last chunk to be assigned, which may have fewer iterations. If no *n* is specified, the default is 1.
`-par-schedule-guided` or `/Qpar-schedule-guided`	Can be used to specify a minimum number of iterations. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. For a chunk of size 1, the size of each chunk is proportional to the number of unassigned iterations divided by the number of threads, decreasing to 1. For an *n* with value *k* (greater than 1), the size of each chunk is determined in the same way with the restriction that the chunks do not contain fewer than *k* iterations (except for the last chunk to be assigned, which may have fewer than *k* iterations). If no *n* is specified, the default is 1.

Option	Description
`-par-schedule-guided-analytical` or `/Qpar-schedule-guided-analytical`	Divides iterations by using exponential distribution or dynamic distribution. The method depends on run-time implementation. Loop bounds are calculated with faster synchronization and chunks are dynamically dispatched at run time by threads in the team.
`-par-schedule-runtime` or `/Qpar-schedule-runtime`	Defers the scheduling decision until run time. The scheduling algorithm and chunk size are then taken from the setting of environment variable OMP_SCHEDULE.

Alternate Options

None

par-threshold, Qpar-threshold

Sets a threshold for the auto-parallelization of loops.

IDE Equivalent

Windows: **Optimization > Threshold For Auto-Parallelization**

Linux: None

Mac OS X: **Optimization > Threshold For Auto-Parallelization**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-par-threshold[`*n*`]`

Windows:

`/Qpar-threshold[[:]`*n*`]`

Arguments

n	Is an integer whose value is the threshold for the auto-parallelization of loops. Possible values are 0 through 100. If *n* is 0, loops get auto-parallelized always, regardless of computation work volume. If *n* is 100, loops get auto-parallelized when performance gains are predicted based on the compiler analysis data. Loops get auto-parallelized only if profitable parallel execution is almost certain. The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, *n*=50 directs the compiler to parallelize only if there is a 50% probability of the code speeding up if executed in parallel.

Default

`-par-threshold100` or `/Qpar-threshold100`	Loops get auto-parallelized only if profitable parallel execution is almost certain. This is also the default if you do not specify *n*.

Description

This option sets a threshold for the auto-parallelization of loops based on the probability of profitable execution of the loop in parallel. To use this option, you must also specify `-parallel` (Linux and Mac OS X) or `/Qparallel` (Windows).

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

Alternate Options

None

parallel, Qparallel

Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

IDE Equivalent

Windows: **Optimization > Parallelization**

Linux: None

Mac OS X: **Optimization > Parallelization**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-parallel`

Windows:

`/Qparallel`

Arguments

None

Default

OFF	Multithreaded code is not generated for loops that can be safely executed in parallel.

Description

This option tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

To use this option, you must also specify option `O2` or `O3`.

NOTE. On Mac OS X systems, when you enable automatic parallelization, you must also set the `DYLD_LIBRARY_PATH` environment variable within Xcode or an error will be displayed.

Alternate Options

None

- `O`

pc, Qpc

Enables control of floating-point significand precision.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-pc`*n*

Windows:

`/Qpc`*n*

Arguments

n	Is the floating-point significand precision. Possible values are:
	`32` Rounds the significand to 24 bits (single precision).
	`64` Rounds the significand to 53 bits (double precision).
	`80` Rounds the significand to 64 bits (extended precision).

Default

`-pc80` or `/Qpc64`	On Linux* and Mac OS* X systems, the floating-point significand is rounded to 64 bits. On Windows* systems, the floating-point significand is rounded to 53 bits.

Description

This option enables control of floating-point significand precision.

Some floating-point algorithms are sensitive to the accuracy of the significand, or fractional part of the floating-point value. For example, iterative operations like division and finding the square root can run faster if you lower the precision with the this option.

Note that a change of the default precision control or rounding mode, for example, by using the `-pc32` (Linux and Mac OS X) or `/Qpc32` (Windows) option or by user intervention, may affect the results returned by some of the mathematical functions.

Alternate Options

None

Floating-point Operations: Floating-point Options Quick Reference

mp1, Qprec

Improves floating-point precision and consistency.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-mp1`

Windows:

`/Qprec`

Arguments

None

Default

OFF	The compiler provides good accuracy and run-time performance at the expense of less consistent floating-point results.

Description

This option improves floating-point consistency. It ensures the out-of-range check of operands of transcendental functions and improves the accuracy of floating-point compares.

This option prevents the compiler from performing optimizations that change NaN comparison semantics and causes all values to be truncated to declared precision before they are used in comparisons. It also causes the compiler to use library routines that give better precision results compared to the X87 transcendental instructions.

This option disables fewer optimizations and has less impact on performance than option `flt-consistency` or `mp`.

Alternate Options

None

See Also

-
-
- fltconsistency
- mp

prec-div, Qprec-div

Improves precision of floating-point divides.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

-prec-div

-no-prec-div

Windows:

/Qprec-div

/Qprec-div-

Arguments

None

Default

-prec-div or/Qprec-div	The compiler uses this method for floating-point divides.

Description

This option improves precision of floating-point divides. It has a slight impact on speed.

With some optimizations, such as `-xSSE2` (Linux) or `/QxSSE2` (Windows), the compiler may change floating-point division computations into multiplication by the reciprocal of the denominator. For example, A/B is computed as A * (1/B) to improve the speed of the computation.

However, sometimes the value produced by this transformation is not as accurate as full IEEE division. When it is important to have fully precise IEEE division, use this option to disable the floating-point division-to-multiplication optimization. The result is more accurate, with some loss of performance.

If you specify `-no-prec-div` (Linux and Mac OS X) or `/Qprec-div-` (Windows), it enables optimizations that give slightly less precise results than full IEEE division.

Alternate Options

None

-

Floating-point Operations: Floating-point Options Quick Reference

prec-sqrt, Qprec-sqrt

Improves precision of square root implementations.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-prec-sqrt
```

```
-no-prec-sqrt
```

Windows:

```
/Qprec-sqrt
```

/Qprec-sqrt-

Arguments

None

Default

-no-prec-sqrt or /Qprec-sqrt-	The compiler uses a faster but less precise implementation of square root. However, the default is -prec-sqrt or /Qprec-sqrt if any of the following options are specified: /Od, /Op, or /Qprec on Windows systems; -O0, -mp (or -fltconsistency), or -mp1 on Linux and Mac OS X systems.

Description

This option improves precision of square root implementations. It has a slight impact on speed.

This option inhibits any optimizations that can adversely affect the precision of a square root computation. The result is fully precise square root implementations, with some loss of performance.

Alternate Options

None

prof-data-order, Qprof-data-order

Enables or disables data ordering if profiling information is enabled.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

-prof-data-order

`-no-prof-data-order`

Mac OS X:

`None`

Windows:

`/Qprof-data-order`

`/Qprof-data-order-`

Arguments

None

Default

`-no-prof-data-order` or `/Qprof-data-order-`	Data ordering is disabled.

Description

This option enables or disables data ordering if profiling information is enabled. It controls the use of profiling information to order static program data items.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify `-prof-gen=globdata` (Linux) or `/Qprof-gen:globdata` (Windows).
- For feedback compilation, you must specify `-prof-use` (Linux) or `/Qprof-use` (Windows). You must not use multi-file optimization by specifying options such as option `-ipo` (Linux) or `/Qipo` (Windows), or option `-ipo-c` (Linux) or `/Qipo-c` (Windows).

Alternate Options

None

prof-dir, Qprof-dir

Specifies a directory for profiling information output files.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-dir` *dir*

Windows:

`/Qprof-dir` *dir*

Arguments

dir	Is the name of the directory.

Default

OFF	Profiling output files are placed in the directory where the program is compiled.

Description

This option specifies a directory for profiling information output files (*.dyn and *.dpi). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Alternate Options

prof-file, Qprof-file

Specifies an alternate file name for the profiling summary files.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-file` *`file`*

Windows:

`/Qprof-file` *`file`*

Arguments

`file`	Is the name of the profiling summary file.

Default

OFF	The profiling summary files have the file name pgopti.*

Description

This option specifies an alternate file name for the profiling summary files. The *`file`* is used as the base name for files created by different profiling passes.

If you add this option to profmerge, the .dpi file will be named *`file`*.dpi instead of pgopti.dpi.

If you specify `-prof-genx` (Linux and Mac OS X) or `/Qprof-genx` (Windows) with this option, the .spi and .spl files will be named *`file`*.spi and *`file`*.spl instead of pgopti.spi and pgopti.spl.

If you specify `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) with this option, the .dpi file will be named *`file`*.dpi instead of pgopti.dpi.

Alternate Options

None

Optimizing Applications:

Profile-guided Optimizations Overview

Coding Guidelines for Intel(R) Architectures

Profile an Application

prof-func-order, Qprof-func-order

Enables or disables function ordering if profiling information is enabled.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-prof-func-order`

`-no-prof-func-order`

Mac OS X:

`None`

Windows:

`/Qprof-func-order`

`/Qprof-func-order-`

Arguments

None

Default

`-no-prof-func-order` or `/Qprof-func-order-`	Function ordering is disabled.

Description

This option enables or disables function ordering if profiling information is enabled.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify `-prof-gen=srcpos` (Linux) or `/Qprof-gen:srcpos` (Windows).
- For feedback compilation, you must specify `-prof-use` (Linux) or `/Qprof-use` (Windows). You must not use multi-file optimization by specifying options such as option `-ipo` (Linux) or `/Qipo` (Windows), or option `-ipo-c` (Linux) or `/Qipo-c` (Windows).

If you enable profiling information by specifying option `-prof-use` (Linux) or `/Qprof-use` (Windows), `-prof-func-groups` (Linux) and `/Qprof-func-groups` (Windows) are set and function grouping is enabled. However, if you explicitly enable `-prof-func-order` (Linux) or `/Qprof-func-order` (Windows), function ordering is performed instead of function grouping.

On Linux* systems, this option is only available for Linux linker 2.15.94.0.1, or later.

To set the hotness threshold for function grouping and function ordering, use option `-prof-hotness-threshold` (Linux) or `/Qprof-hotness-threshold` (Windows).

Alternate Options

None

The following example shows how to use this option on a Windows system:

```
ifort /Qprof-gen:globdata file1.f90 file2.f90 /exe:instrumented.exe
    ./instrumented.exe
ifort /Qprof-use /Qprof-func-order file1.f90 file2.f90 /exe:feedback.exe
```

The following example shows how to use this option on a Linux system:

```
ifort -prof-gen:globdata file1.f90 file2.f90 -o instrumented
    ./instrumented.exe
ifort -prof-use -prof-func-order file1.f90 file2.f90 -o feedback
```

prof-gen, Qprof-gen

Produces an instrumented object file that can be used in profile-guided optimization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-gen[=keyword]`

`-no-prof-gen`

Windows:

`/Qprof-gen[:keyword]`

`/Qprof-gen-`

Arguments

keyword	Specifies details for the instrumented file. Possible values are:	
	`default`	Produces an instrumented object file. This is the same as specifying `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*) with no keyword.
	`srcpos`	Produces an instrumented object file that includes extra source position information. This option is the same as option `-prof-genx` (Linux* and Mac OS* X) or `/Qprof-genx` (Windows*), which are deprecated.
	`globdata`	Produces an instrumented object file that includes information for global data layout.

Default

`-no-prof-gen` or `/Qprof-` Profile generation is disabled.
`gen-`

Description

This option produces an instrumented object file that can be used in profile-guided optimization. It gets the execution count of each basic block.

If you specify keyword `srcpos` or `globdata`, a static profile information file (.spi) is created. These settings may increase the time needed to do a parallel build using -prof-gen, because of contention writing the .spi file.

These options are used in phase 1 of the Profile Guided Optimizer (PGO) to instruct the compiler to produce instrumented code in your object files in preparation for instrumented execution.

Alternate Options

None

See Also

•
•

Optimizing Applications:

Basic PGO Options

Example of Profile-Guided Optimization

prof-genx, Qprof-genx

This is a deprecated option. See prof-gen keyword `srcpos`*.*

prof-hotness-threshold, Qprof-hotness-threshold

Lets you set the hotness threshold for function grouping and function ordering.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-prof-hotness-threshold=`*n*

Mac OS X:

`None`

Windows:

`/Qprof-hotness-threshold:`*n*

Arguments

n	Is the hotness threshold. *n* is a percentage having a value between 0 and 100 inclusive. If you specify 0, there will be no hotness threshold setting in effect for function grouping and function ordering.

Default

OFF	The compiler's default hotness threshold setting of 10 percent is in effect for function grouping and function ordering.

Description

This option lets you set the hotness threshold for function grouping and function ordering.

The "hotness threshold" is the percentage of functions in the application that should be placed in the application's hot region. The hot region is the most frequently executed part of the application. By grouping these functions together into one hot region, they have a greater probability of remaining resident in the instruction cache. This can enhance the application's performance.

For this option to take effect, you must specify option `-prof-use` (Linux) or `/Qprof-use` (Windows) and one of the following:

- On Linux systems: `-prof-func-groups` or `-prof-func-order`
- On Windows systems: `/Qprof-func-order`

Alternate Options

None

See Also

-
-
- prof-use, Qprof-use
- prof-func-groups
- prof-func-order, Qprof-func-order

prof-src-dir, Qprof-src-dir

Determines whether directory information of the source file under compilation is considered when looking up profile data records.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-src-dir`

`-no-prof-src-dir`

Windows:

`/Qprof-src-dir`

`/Qprof-src-dir-`

Arguments

None

Default

`-prof-src-dir` or `/Qprof-src-dir`	Directory information is used when looking up profile data records in the .dpi file.

Description

This option determines whether directory information of the source file under compilation is considered when looking up profile data records in the .dpi file. To use this option, you must also specify option `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows).

If the option is enabled, directory information is considered when looking up the profile data records within the .dpi file. You can specify directory information by using one of the following options:

- Linux and Mac OS X: `-prof-src-root` or `-prof-src-root-cwd`
- Windows: `/Qprof-src-root` or `/Qprof-src-root-cwd`

If the option is disabled, directory information is ignored and only the name of the file is used to find the profile data record.

Note that options `-prof-src-dir` (Linux and Mac OS X) and `/Qprof-src-dir` (Windows) control how the names of the user's source files get represented within the .dyn or .dpi files. Options `-prof-dir` (Linux and Mac OS X) and `/Qprof-dir` (Windows) specify the location of the .dyn or the .dpi files.

Alternate Options

None

See Also

-
-
- `prof-use, Qprof-use`
- `prof-src-root, Qprof-src-root`
- `prof-src-root-cwd, Qprof-src-root-cwd`

prof-src-root, Qprof-src-root

Lets you use relative directory paths when looking up profile data and specifies a directory as the base.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-src-root=`*`dir`*

Windows:

`/Qprof-src-root:`*`dir`*

Arguments

`dir`	Is the base for the relative paths.

Default

OFF	The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It lets you specify a directory as the base. The paths are relative to a base directory specified during the `-prof-gen` (Linux and Mac OS X) or `/Qprof-gen` (Windows) compilation phase.

This option is available during the following phases of compilation:

- Linux and Mac OS X: `-prof-gen` and `-prof-use` phases
- Windows: `/Qprof-gen` and `/Qprof-use` phases

When this option is specified during the `-prof-gen` or `/Qprof-gen` phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the `-prof-use` or `/Qprof-use` phase, it specifies a root directory that replaces the root directory specified at the `-prof-gen` or `/Qprof-gen` phase for forming the lookup keys.

To be effective, this option or option `-prof-src-root-cwd` (Linux and Mac OS X) or `/Qprof-src-root-cwd` (Windows) must be specified during the `-prof-gen` or `/Qprof-gen` phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

Alternate Options

None

Consider the initial `-prof-gen` compilation of the source file c:\user1\feature_foo\myproject\common\glob.f90:

```
ifort -prof-gen -prof-src-root=c:\user1\feature_foo\myproject -c common\glob.f90
```

For the `-prof-use` phase, the file glob.f90 could be moved into the directory c:\user2\feature_bar\myproject\common\glob.f90 and profile information would be found from the .dpi when using the following:

```
ifort -prof-use -prof-src-root=c:\user2\feature_bar\myproject -c common\glob.f90
```

If you do not use option `-prof-src-root` during the `-prof-gen` phase, by default, the `-prof-use` compilation can only find the profile data if the file is compiled in the c:\user1\feature_foo\my_project\common directory.

See Also

-
-
- prof-gen, Qprof-gen
- prof-use, Qprof-use
- prof-src-dir, Qprof-src-dir
- prof-src-root-cwd, Qprof-src-root-cwd

prof-src-root-cwd, Qprof-src-root-cwd

Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-prof-src-root-cwd
```

Windows:

```
/Qprof-src-root-cwd
```

Arguments

None

Default

OFF	The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It specifies the current working directory as the base. To use this option, you must also specify option `-prof-use` (Linux and Mac OS) or `/Qprof-use` (Windows).

This option is available during the following phases of compilation:

- Linux and Mac OS X: `-prof-gen` and `-prof-use` phases
- Windows: `/Qprof-gen` and `/Qprof-use` phases

When this option is specified during the `-prof-gen` or `/Qprof-gen` phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the `-prof-use` or `/Qprof-use` phase, it specifies a root directory that replaces the root directory specified at the `-prof-gen` or `/Qprof-gen` phase for forming the lookup keys.

To be effective, this option or option `-prof-src-root` (Linux and Mac OS X) or `/Qprof-src-root` (Windows) must be specified during the `-prof-gen` or `/Qprof-gen` phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

Alternate Options

None

See Also

-
-
- `prof-gen, Qprof-gen`
- `prof-use, Qprof-use`
- `prof-src-dir, Qprof-src-dir`
- `prof-src-root, Qprof-src-root`

prof-use, Qprof-use

Enables the use of profiling information during optimization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-prof-use[=arg]`

`-no-prof-use`

Windows:

`/Qprof-use[:arg]`

`/Qprof-use-`

Arguments

arg Specifies additional instructions. Possible values are:

`weighted` Tells the profmerge utility to apply a weighting to the .dyn file values when creating the .dpi file to normalize the data counts when the training runs have differentexecution durations. This argument only has an effect when the compiler invokes the profmerge utility to create the .dpi file. This argument does not have an effect if the .dpi file was previously created without weighting.

`[no]merge` Enables or disables automatic invocation of the profmerge utility. The default is `merge`. Note that you cannot specify both `weighted` and `nomerge`. If you try to specify both values, a warning will be displayed and `nomerge` takes precedence.

`default` Enables the use of profiling information during optimization. The profmerge utility is invoked by default. This value is the same as specifying `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) with no argument.

Default

`-no-prof-use` or `/Qprof-use-` Profiling information is not used during optimization.

Description

This option enables the use of profiling information (including function splitting and function grouping) during optimization. It enables option `-fnsplit` (Linux) or `/Qfnsplit` (Windows).

This option instructs the compiler to produce a profile-optimized executable and it merges available profiling output files into a pgopti.dpi file.

Note that there is no way to turn off function grouping if you enable it using this option.

To set the hotness threshold for function grouping and function ordering, use option `-prof-hotness-threshold` (Linux) or `/Qprof-hotness-threshold` (Windows).

Alternate Options

None

See Also

-
-
- `prof-hotness-threshold, Qprof-hotness-threshold`

Optimizing Applications:

Basic PGO Options

Example of Profile-Guided Optimization

rcd, Qrcd

Enables fast float-to-integer conversions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-rcd`

Windows:

`/Qrcd`

Arguments

None

Default

OFF	Floating-point values are truncated when a conversion to an integer is involved. On Windows, this is the same as specifying `/QIfist-`.

Description

This option enables fast float-to-integer conversions. It can improve the performance of code that requires floating-point-to-integer conversions.

The system default floating-point rounding mode is round-to-nearest. However, the Fortran language requires floating-point values to be truncated when a conversion to an integer is involved. To do this, the compiler must change the rounding mode to truncation before each floating-point-to-integer conversion and change it back afterwards.

This option disables the change to truncation of the rounding mode for all floating-point calculations, including floating point-to-integer conversions. This option can improve performance, but floating-point conversions to integer will not conform to Fortran semantics.

Alternate Options

Linux and Mac OS X: None

Windows: `/QIfist`

rct, Qrct

Sets the internal FPU rounding control to Truncate.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-rct`

Windows:

`/Qrct`

Arguments

None

Default

OFF	The compiler uses the default setting for the FPU rounding control.

Description

This option sets the internal FPU rounding control to Truncate.

Alternate Options

Linux and Mac OS X: None

Windows: `/rounding-mode:chopped`

safe-cray-ptr, Qsafe-cray-ptr

Tells the compiler that Cray pointers do not alias other variables.*

IDE Equivalent

Windows: **Data > Assume Cray Pointers Do Not Share Memory Locations**

Linux: None

Mac OS X: **Data > Assume Cray Pointers Do Not Share Memory Locations**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-safe-cray-ptr`

Windows:

`/Qsafe-cray-ptr`

Arguments

None

Default

OFF	The compiler assumes that Cray pointers alias other variables.

Description

This option tells the compiler that Cray pointers do not alias (that is, do not specify sharing memory with) other variables.

Alternate Options

None

Example

Consider the following:

```
pointer (pb, b)
pb = getstorage()
do i = 1, n
b(i) = a(i) + 1
enddo
```

By default, the compiler assumes that b and a are aliased. To prevent such an assumption, specify the `-safe-cray-ptr` (Linux and Mac OS X) or `/Qsafe-cray-ptr` (Windows) option, and the compiler will treat b(i) and a(i) as independent of each other.

However, if the variables are intended to be aliased with Cray pointers, using the option produces incorrect results. In the following example, you should not use the option:

```
pointer (pb, b)
pb = loc(a(2))
do i=1, n
b(i) = a(i) +1
enddo
```

save, Qsave

Causes variables to be placed in static memory.

IDE Equivalent

Windows: **Data > Local Variable Storage**

Linux: None

Mac OS X: **Data > Local Variable Storage**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-save
```

Windows:

```
/Qsave
```

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`	Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that if option `recursive`, `-openmp` (Linux and Mac OS X), or `/Qopenmp` (Windows) is specified, the default is `-automatic` (Linux) or `/Qauto` (Windows).

Description

This option saves all variables in static allocation except local variables within a recursive routine and variables declared as AUTOMATIC.

If you want all local, non-SAVEd variables to be allocated to the run-time stack, specify option `automatic`.

Alternate Options

Linux and Mac OS X: `-noautomatic`, `-noauto`

Windows: `/noautomatic`, `/noauto`, `/4Na`

See Also

-
-
- `automatic`
- `auto_scalar`

save-temps, Qsave-temps

Tells the compiler to save intermediate files created during compilation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-save-temps`

`-no-save-temps`

Windows:

`/Qsave-temps`

`/Qsave-temps-`

Arguments

None

Default

Linux and Mac OS X: `-no-save-temps` Windows: .obj files are saved	On Linux and Mac OS X systems, the compiler deletes intermediate files after compilation is completed. On Windows systems, the compiler saves only intermediate object files after compilation is completed.

Description

This option tells the compiler to save intermediate files created during compilation. The names of the files saved are based on the name of the source file; the files are saved in the current working directory.

If `-save-temps` or `/Qsave-temps` is specified, the following occurs:

- The object .o file (Linux and Mac OS X) or .obj file (Windows) is saved.
- The assembler .s file (Linux and Mac OS X) or .asm file (Windows) is saved if you specified -use-asm (Linux or Mac OS X) or /Quse-asm (Windows).
- The .i or .i90 file is saved if the fpp preprocessor is invoked.

If `-no-save-temps` is specified on Linux or Mac OS X systems, the following occurs:

- The .o file is put into `/tmp` and deleted after calling `ld`.
- The preprocessed file is not saved after it has been used by the compiler.

If `/Qsave-temps-` is specified on Windows systems, the following occurs:

- The .obj file is not saved after the linker step.
- The preprocessed file is not saved after it has been used by the compiler.

NOTE. This option only saves intermediate files that are normally created during compilation.

Alternate Options

None

Example

If you compile program `my_foo.F` on a Linux or Mac OS X system and you specify option `-save-temps` and option `-use-asm`, the compilation will produce `files my_foo.o`, `my_foo.s`, and `my_foo.i`.

If you compile program `my_foo.fpp` on a Windows system and you specif option `/Qsave-temps` and option `/Quse-asm`, the compilation will produce `files my_foo.obj`, `my_foo.asm`, and `my_foo.i`.

scalar-rep, Qscalar-rep

Enables scalar replacement performed during loop transformation.

IDE Equivalent

None

Architectures

IA-32 architecture

Syntax

Linux and Mac OS X:

`-scalar-rep`

`-no-scalar-rep`

Windows:

`/Qscalar-rep`

/Qscalar-rep-

Arguments

None

Default

-no-scalar-rep or/Qscalar-rep-	Scalar replacement is not performed during loop transformation.

Description

This option enables scalar replacement performed during loop transformation. To use this option, you must also specify O3.

Alternate Options

None

See Also

-
-
- O

Qsfalign

Specifies stack alignment for functions.

IDE Equivalent

None

Architectures

IA-32 architecture

Syntax

Linux and Mac OS X:

None

Windows:

/Qsfalign[*n*]

Arguments

n	Is the byte size of aligned variables. Possible values are:
8	Specifies that alignment should occur for functions with 8-byte aligned variables. At this setting the compiler aligns the stack to 16 bytes if there is any 16-byte or 8-byte data on the stack. For 8-byte data, the compiler only aligns the stack if the alignment will produce a performance advantage.
16	Specifies that alignment should occur for functions with 16-byte aligned variables. At this setting, the compiler only aligns the stack for 16-byte data. No attempt is made to align for 8-byte data.

Default

/Qsfalign8	Alignment occurs for functions with 8-byte aligned variables.

Description

This option specifies stack alignment for functions. It lets you disable the normal optimization that aligns a stack for 8-byte data.

If you do not specify *n*, stack alignment occurs for all functions. If you specify /Qsfalign-, no stack alignment occurs for any function.

Alternate Options

None

sox, Qsox

Tells the compiler to save the compilation options and version number in the Linux OS executable or the Windows* OS object file.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-sox`

`-no-sox`

Mac OS X:

`None`

Windows:

`/Qsox`

`/Qsox-`

Arguments

None

Default

`-no-sox` or `/Qsox-`	The compiler does not save the compiler options and version number in the executable.

Description

Tells the compiler to save the compilation options and version number in the Linux* OS executable or the Windows* OS object file.

On Linux systems, the size of the executable on disk is increased slightly by the inclusion of these infotmation strings.

This option forces the compiler to embed in each object file or assembly output a string that contains information about the compiler version and compilation options for each source file that has been compiled.

On Windows systems, the information stays in the object file. On Linux systems, when you link the object files into an executable file, the linker places each of the information strings into the header of the executable. It is then possible to use a tool, such as a strings utility, to determine what options were used to build the executable file.

If `-no-sox` or `/Qsox-` is specified, this extra information is not put into the object or assembly output generated by the compiler.

Alternate Options

None

tcheck, Qtcheck

Enables analysis of threaded applications.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tcheck`

Mac OS X:

`None`

Windows:

`/Qtcheck`

Arguments

None

Default

OFF	Threaded applications are not instrumented by the compiler for analysis by Intel® Thread Checker.

Description

This option enables analysis of threaded applications.

To use this option, you must have Intel® Thread Checker installed, which is one of the Intel® Threading Analysis Tools. If you do not have this tool installed, the compilation will fail. Remove the `-tcheck` (Linux) or `/Qtcheck` (Windows) option from the command line and recompile.

For more information about Intel® Thread Checker (including an evaluation copy), open the page associated with threading tools at Intel® Software Development Products.

Alternate Options

None

tcollect, Qtcollect

Inserts instrumentation probes calling the Intel® Trace Collector API.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tcollect[`*`lib`*`]`

Mac OS X:

`None`

Windows:

`/Qtcollect[:`*`lib`*`]`

Arguments

`lib`	Is one of the Intel® Trace Collector libraries; for example, VT, VTcs, VTmc, or VTfs. If you do not specify *`lib`*, the default library is VT.

Default

OFF	Instrumentation probes are not inserted into compiled applications.

Description

This option inserts instrumentation probes calling the Intel® Trace Collector API. To use this option, you must have the Intel® Trace Collector installed and set up through one of its set-up scripts. This tool is a component of the Intel® Trace Analyzer and Collector.

This option provides a flexible and convenient way of instrumenting functions of a compiled application. For every function, the entry and exit points are instrumented at compile time to let the Intel® Trace Collector record functions beyond the default MPI calls. For non-MPI applications (for example, threaded or serial), you must ensure that the Intel® Trace Collector is properly initialized (VT_initialize/VT_init).

CAUTION. Be careful with full instrumentation because this feature can produce very large trace files.

For more details, see the Intel® Trace Collector User Guide.

Alternate Options

None

See Also

-
-
- tcollect-filter, Qtcollect-filter

tcollect-filter, Qtcollect-filter

Lets you enable or disable the instrumentation of specified functions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tcollect-filter` *file*

Mac OS X:

`None`

Windows:

`/Qtcollect-filter:`*file*

Arguments

file	Is a configuration file that lists filters, one per line. Each filter consists of a regular expression string and a switch. Strings with leading or trailing white spaces must be quoted. Other strings do not have to be quoted. The switch value can be ON, on, OFF, or off.

Default

OFF	Functions are not instrumented. However, if option `-tcollect` (Linux) or `/Qtcollect` (Windows) is specified, the filter setting is ".* ON" and all functions get instrumented.

Description

This option lets you enable or disable the instrumentation of specified functions.

During instrumentation, the regular expressions in the file are matched against the function names. The switch specifies whether matching functions are to be instrumented or not. Multiple filters are evaluated from top to bottom with increasing precedence.

The names of the functions to match against are formatted as follows:

- The source file name is followed by a colon-separated function name. Source file names should contain the full path, if available. For example:
  `/home/joe/src/file.f:FOO_bar`
- Classes and function names are separated by double colons. For example:
  `/home/joe/src/file.fpp:app::foo::bar`

You can use option `-opt-report` (Linux) or `/Qopt-report` (Windows) to get a full list of file and function names that the compiler recognizes from the compilation unit. This list can be used as the basis for filtering in the configuration file.

To use this option, you must have the Intel® Trace Collector installed and set up through one of its set-up scripts. This tool is a component of the Intel® Trace Analyzer and Collector.

For more details, see the Intel® Trace Collector User Guide.

Alternate Options

None

Consider the following filters in a configuration file:

```
'.*' OFF '.*vector.*' ON
```

The above will cause instrumentation of only those functions having the string 'vector' in their names. No other function will be instrumented. Note that reversing the order of the two lines will prevent instrumentation of all functions.

To get a list of the file or routine strings that can be matched by the regular expression filters, generate an optimization report with tcollect information. For example:

```
Windows OS: ifort /Qtcollect /Qopt-report /Qopt-report-phase tcollect

Linux OS: ifort -tcollect -opt-report -opt-report-phase tcollect
```

See Also

-
-
- tcollect, Qtcollect

tprofile, Qtprofile

Generates instrumentation to analyze multi-threading performance.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tprofile`

Mac OS X:

`None`

Windows:

`/Qtprofile`

Arguments

None

Default

OFF	Instrumentation is not generated by the compiler for analysis by Intel® Thread Profiler.

Description

This option generates instrumentation to analyze multi-threading performance.

To use this option, you must have Intel® Thread Profiler installed, which is one of the Intel® Threading Analysis Tools. If you do not have this tool installed, the compilation will fail. Remove the `-tprofile` (Linux) or `/Qtprofile` (Windows) option from the command line and recompile.

For more information about Intel® Thread Profiler (including an evaluation copy), open the page associated with threading tools at Intel® Software Development Products.

Alternate Options

None

ftrapuv, Qtrapuv

Initializes stack local variables to an unusual value to aid error detection.

IDE Equivalent

Windows: **Data > Initialize stack variables to an unusual value**

Linux: None

Mac OS X: **Run-Time > Initialize Stack Variables to an Unusual Value**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-ftrapuv`

Windows:

`/Qtrapuv`

Arguments

None

Default

OFF	The compiler does not initialize local variables.

Description

This option initializes stack local variables to an unusual value to aid error detection. Normally, these local variables should be initialized in the application.

The option sets any uninitialized local variables that are allocated on the stack to a value that is typically interpreted as a very large integer or an invalid address. References to these variables are then likely to cause run-time errors that can help you detect coding errors.

This option sets option `-g` (Linux and Mac OS X) and `/Zi` or `/Z7` (Windows).

Alternate Options

None

See Also

-
-
- `g`, `Zi`, `Z7`

unroll, Qunroll

Tells the compiler the maximum number of times to unroll loops.

IDE Equivalent

Windows: **Optimization > Loop Unroll Count**

Linux: None

Mac OS X: **Optimization > Loop Unroll Count**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-unroll[=n]`

Windows:

`/Qunroll[:n]`

Arguments

n	Is the maximum number of times a loop can be unrolled. To disable loop enrolling, specify 0. On systems using IA-64 architecture, you can only specify a value of 0.

Default

`-unroll` or `/Qunroll`	The compiler uses default heuristics when unrolling loops.

Description

This option tells the compiler the maximum number of times to unroll loops.

If you do not specify *n*, the optimizer determines how many times loops can be unrolled.

Alternate Options

Linux and Mac OS X: `-funroll-loops`

Windows: `/unroll`

See Also

-
-

Optimizing Applications: Loop Unrolling

unroll-aggressive, Qunroll-aggressive

Determines whether the compiler uses more aggressive unrolling for certain loops.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-unroll-aggressive`

`-no-unroll-aggressive`

Windows:

`/Qunroll-aggressive`

`/Qunroll-aggressive-`

Arguments

None

Default

`-no-unroll-aggressive` or `/Qunroll-aggressive-`	The compiler uses default heuristics when unrolling loops.

Description

This option determines whether the compiler uses more aggressive unrolling for certain loops. The positive form of the option may improve performance.

On IA-32 architecture and Intel® 64 architecture, this option enables aggressive, complete unrolling for loops with small constant trip counts.

On IA-64 architecture, this option enables additional complete unrolling for loops that have multiple exits or outer loops that have a small constant trip count.

Alternate Options

None

uppercase, Quppercase

See names.

use-asm, Quse-asm

Tells the compiler to produce objects through the assembler.

IDE Equivalent

None

Architectures

`-use-asm`: IA-32 architecture, Intel® 64 architecture, IA-64 architecture

`/Quse-asm`: IA-64 architecture

Syntax

Linux and Mac OS X:

```
-use-asm
```

```
-no-use-asm
```

Windows:

```
/Quse-asm
```

```
/Quse-asm-
```

Arguments

None

Default

`-no-use-asm` or `/Quse-asm-`	The compiler produces objects directly.

Description

This option tells the compiler to produce objects through the assembler.

Alternate Options

None

Quse-msasm-symbols

Tells the compiler to use a dollar sign ("$") when producing symbol names.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Quse-msasm-symbols`

Arguments

None

Default

OFF	The compiler uses a period (".") when producing symbol names

Description

This option tells the compiler to use a dollar sign ("$") when producing symbol names.

Use this option if you require symbols in your .asm files to contain characters that are accepted by the MS assembler.

Alternate Options

None

Quse-vcdebug

Tells the compiler to issue debug information compatible with the Visual C++ debugger.

IDE Equivalent

None

Architectures

IA-32 architecture

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Quse-vcdebug`

Arguments

None

Default

OFF	Debug information is issued that is compatible with Fortran debuggers.

Description

This option tells the compiler to issue debug information compatible with the Visual C++ debugger. It prevents the compiler from issuing the extended information used by Fortran debuggers.

Alternate Options

None

Qvc

Specifies compatibility with Microsoft Visual C++ or Microsoft* Visual Studio.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Qvc7.1`

`/Qvc8`

`/Qvc9`

Arguments

None

Default

varies	When the compiler is installed, it detects which version of Visual Studio is on your system. `Qvc` defaults to the form of the option that is compatible with that version. When multiple versions of

Visual Studio are installed, the compiler installation lets you select which version you want to use. In this case, `Qvc` defaults to the version you choose.

Description

This option specifies compatibility with Visual C++ or Visual Studio.

Option	Description
`/Qvc7.1`	Specifies compatibility with Microsoft* Visual Studio .NET 2003.
`/Qvc8`	Specifies compatibility with Microsoft* Visual Studio 2005.
`/Qvc9`	Specifies compatibility with Microsoft* Visual Studio 2008.

Alternate Options

None

vec, Qvec

Enables or disables vectorization and transformations enabled for vectorization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-vec
-no-vec
```

Windows:

`/Qvec`

`/Qvec-`

Arguments

None

Default

`-vec` or `/Qvec`	Vectorization is enabled.

Description

This option enables or disables vectorization and transformations enabled for vectorization.

To disable vectorization and transformations enabled for vectorization, specify `-no-vec` (Linux and Mac OS X) or `/Qvec-` (Windows).

Alternate Options

None

See Also

-
-
- `ax, Qax`
- `x, Qx`
- `vec-report, Qvec-report`
- `vec-guard-write, Qvec-guard-write`
- `vec-threshold, Qvec-threshold`

vec-guard-write, Qvec-guard-write

Tells the compiler to perform a conditional check in a vectorized loop.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-vec-guard-write`

`-no-vec-guard-write`

Windows:

`/Qvec-guard-write`

`/Qvec-guard-write-`

Arguments

None

Default

`-no-vec-guard-write` or `/Qvec-guard-write-`	The compiler uses default heuristics when checking vectorized loops.

Description

This option tells the compiler to perform a conditional check in a vectorized loop. This checking avoids unnecessary stores and may improve performance.

Alternate Options

None

vec-report, Qvec-report

Controls the diagnostic information reported by the vectorizer.

IDE Equivalent

Windows: **Compilation Diagnostics > Vectorizer Diagnostic Level**

Linux: None

Mac OS X: **Diagnostics > Vectorizer Diagnostic Report**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-vec-report[n]`

Windows:

`/Qvec-report[n]`

Arguments

n	Is a value denoting which diagnostic messages to report. Possible values are:
0	Tells the vectorizer to report no diagnostic information.
1	Tells the vectorizer to report on vectorized loops.
2	Tells the vectorizer to report on vectorized and non-vectorized loops.
3	Tells the vectorizer to report on vectorized and non-vectorized loops and any proven or assumed data dependences.
4	Tells the vectorizer to report on non-vectorized loops.
5	Tells the vectorizer to report on non-vectorized loops and the reason why they were not vectorized.

Default

`-vec-report1` or `/Qvec-report1`	If the vectorizer has been enabled and you do not specify *n*, the compiler reports diagnostics on vectorized loops. If you do not specify the option on the command line, the default is to display no messages.

Description

This option controls the diagnostic information reported by the vectorizer. The vectorizer report is sent to stdout.

If you do not specify *n*, it is the same as specifying `-vec-report1` (Linux and Mac OS X) or `/Qvec-report1` (Windows).

The vectorizer is enabled when certain compiler options are specified, such as option `-ax` or `-x` (Linux and Mac OS X), option `/Qax` or `/Qx` (Windows), option `-arch SSE` or `-arch SSE2` (Linux and Mac OS X), option `/architecture:SSE` or `/architecture:SSE2` (Windows).

If this option is specified from within the IDE, the report is included in the build log if the Generate Build Logs option is selected.

Alternate Options

None

vec-threshold, Qvec-threshold

Sets a threshold for the vectorization of loops.

IDE Equivalent

Windows: **Optimization > Threshold For Vectorization**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-vec-threshold[`*n*`]`

Windows:

`/Qvec-threshold[[:]`*n*`]`

Arguments

n	Is an integer whose value is the threshold for the vectorization of loops. Possible values are 0 through 100. If *n* is 0, loops get vectorized always, regardless of computation work volume. If *n* is 100, loops get vectorized when performance gains are predicted based on the compiler analysis data. Loops get vectorized only if profitable vector-level parallel execution is almost certain. The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, *n*=50 directs the compiler to vectorize only if there is a 50% probability of the code speeding up if executed in vector form.

Default

`-vec-threshold100` or `/Qvec-threshold100`	Loops get vectorized only if profitable vector-level parallel execution is almost certain. This is also the default if you do not specify *n*.

Description

This option sets a threshold for the vectorization of loops based on the probability of profitable execution of the vectorized loop in parallel.

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

Alternate Options

None

x, Qx

Tells the compiler to generate optimized code specialized for the Intel processor that executes your program.

IDE Equivalent

Windows: **Code Generation > Intel Processor-Specific Optimization**

Optimization > Use Intel(R) Processor Extensions

Linux: None

Mac OS X: **Code Generation > Intel Processor-Specific Optimization**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

-xprocessor

Windows:

/Qxprocessor

Arguments

processor Indicates the processor for which code is generated. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (Intel® SSSE). Possible values are:

`Host` Can generate instructions for the highest instruction set available on the compilation host processor.
On Intel processors, this may correspond to the most suitable `-x` (Linux* and Mac OS* X) or `/Qx` (Windows*) option. On non-Intel processors, this may correspond to the most suitable `-m` (Linux and Mac OS X) or `/arch` (Windows) option.

	The resulting executable may not run on a processor different from the host in the following cases: • If the processor does not support all of the instructions supported by the host processor. • If the host is an Intel processor and the other processor is a non-Intel processor.
`AVX`	Optimizes for Intel processors that support Intel® Advanced Vector Extensions (Intel® AVX).
`SSE4.2`	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.
`SSE4.1`	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture. This replaces value S, which is deprecated.
`SSE3_ATOM`	Optimizes for the Intel® Atom™ processor and Intel® Centrino® Atom™ Processor Technology. Can generate MOVBE instructions, depending on the setting of option `-minstruction` (Linux and Mac OS) or `/Qinstruction` (Windows).

SSSE3	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. For Mac OS* X systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.
SSE3	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. For Mac OS* X systems, this value is only supported on IA-32 architecture.This replaces value P, which is deprecated.
SSE2	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2. This value is not available on Mac OS* X systems. This replaces value N, which is deprecated.

Default

Windows* systems: None Linux* systems: None Mac OS* X systems using IA-32 architecture: SSE3 Mac OS* X systems using Intel® 64 architecture: SSSE3	On Windows systems, if neither /Qx nor /arch is specified, the default is /arch:SSE2. On Linux systems, if neither -x nor -m is specified, the default is -msse2.

Description

This option tells the compiler to generate optimized code specialized for the Intel processor that executes your program. It also enables optimizations in addition to Intel processor-specific optimizations. The specialized code generated by this option may run only on a subset of Intel processors.

This option can enable optimizations depending on the argument specified. For example, it may enable Intel® Streaming SIMD Extensions 4 (Intel® SSE4), Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3), Intel® Streaming SIMD Extensions 3 (Intel® SSE3), Intel® Streaming SIMD Extensions 2 (Intel® SSE2), or Intel® Streaming SIMD Extensions (Intel® SSE) instructions.

The binaries produced by these values will run on Intel processors that support all of the features for the targeted processor. For example, binaries produced with SSE3 will run on an Intel® Core™ 2 Duo processor, because that processor completely supports all of the capabilities of the Intel® Pentium® 4 processor, which the SSE3 value targets. Specifying the SSSE3 value has the potential of using more features and optimizations available to the Intel® Core™ 2 Duo processor.

Do not use *processor* values to create binaries that will execute on a processor that is not compatible with the targeted processor. The resulting program may fail with an illegal instruction exception or display other unexpected behavior. For example, binaries produced with SSE3 may produce code that will not run on Intel® Pentium® III processors or earlier processors that do not support SSE3 instructions.

Compiling the main program with any of the *processor* values produces binaries that display a fatal run-time error if they are executed on unsupported processors. For more information, see *Optimizing Applications*.

If you specify more than one *processor* value, code is generated for only the highest-performing processor specified. The highest-performing to lowest-performing *processor* values are: SSE4.2, SSE4.1, SSSE3, SSE3, SSE2. Note that *processor* values AVX and SSE3_ATOM do not fit within this group.

Compiler options `m` and `arch` produce binaries that should run on processors not made by Intel that implement the same capabilities as the corresponding Intel processors.

Previous value O is deprecated and has been replaced by option `-msse3` (Linux and Mac OS X) and option `/arch:SSE3` (Windows).

Previous values W and K are deprecated. The details on replacements are as follows:

- Mac OS X systems: On these systems, there is no exact replacement for W or K. You can upgrade to the default option `-msse3` (IA-32 architecture) or option `-mssse3` (Intel® 64 architecture).
- Windows and Linux systems: The replacement for W is `-msse2` (Linux) or `/arch:SSE2` (Windows). There is no exact replacement for K. However, on Windows systems, `/QxK` is interpreted as `/arch:IA32`; on Linux systems, `-xK` is interpreted as `-mia32`. You can also do one of the following:

- Upgrade to option -msse2 (Linux) or option /arch:SSE2 (Windows). This will produce one code path that is specialized for Intel® SSE2. It will not run on earlier processors
- Specify the two option combination -mia32 -axSSE2 (Linux) or /arch:IA32 /QaxSSE2 (Windows). This combination will produce an executable that runs on any processor with IA-32 architecture but with an additional specialized Intel® SSE2 code path.

The -x and /Qx options enable additional optimizations not enabled with option -m or option /arch.

On Windows* systems, options /Qx and /arch are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning. Similarly, on Linux* and Mac OS* X systems, options -x and -m are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

Alternate Options

None

-
-
- ax, Qax
- m
- arch
- minstruction, Qinstruction

zero, Qzero

Initializes to zero all local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are saved but not yet initialized.

IDE Equivalent

Windows: **Data > Initialize Local Saved Scalars to Zero**

Linux: None

Mac OS X: **Data > Initialize Local Saved Scalars to Zero**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-zero`

`-nozero`

Windows:

`/Qzero`

`/Qzero-`

Arguments

None

Default

`-nozero` or `/Qzero-` Local scalar variables are not initialized to zero.

Description

This option initializes to zero all local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are saved but not yet initialized.

Use `-save` (Linux and Mac OS X) or `/Qsave` (Windows) on the command line to make all local variables specifically marked as SAVE.

Alternate Options

None

See Also

-
-
- `save`

r8, r16

See real-size.

rcd, Qrcd

Enables fast float-to-integer conversions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-rcd`

Windows:

`/Qrcd`

Arguments

None

Default

OFF	Floating-point values are truncated when a conversion to an integer is involved. On Windows, this is the same as specifying `/QIfist-`.

Description

This option enables fast float-to-integer conversions. It can improve the performance of code that requires floating-point-to-integer conversions.

The system default floating-point rounding mode is round-to-nearest. However, the Fortran language requires floating-point values to be truncated when a conversion to an integer is involved. To do this, the compiler must change the rounding mode to truncation before each floating-point-to-integer conversion and change it back afterwards.

This option disables the change to truncation of the rounding mode for all floating-point calculations, including floating point-to-integer conversions. This option can improve performance, but floating-point conversions to integer will not conform to Fortran semantics.

Alternate Options

Linux and Mac OS X: None

Windows: `/QIfist`

rct, Qrct

Sets the internal FPU rounding control to Truncate.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-rct`

Windows:

`/Qrct`

Arguments

None

Default

OFF	The compiler uses the default setting for the FPU rounding control.

Description

This option sets the internal FPU rounding control to Truncate.

Alternate Options

Linux and Mac OS X: None

Windows: `/rounding-mode:chopped`

real-size

Specifies the default KIND for real and complex variables.

IDE Equivalent

Windows: **Data > Default Real KIND**

Linux: None

Mac OS X: **Data > Default Real KIND**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-real-size` *`size`*

Windows:

`/real-size:`*`size`*

Arguments

`size`	Is the size for real and complex variables. Possible values are: 32, 64, or 128.

Default

`real-size 32`	Default real and complex variables are 4 bytes long (REAL(KIND=4) and COMPLEX(KIND=4)).

Description

This option specifies the default size (in bits) for real and complex variables.

Option	Description
`real-size 32`	Makes default real and complex variables 4 bytes long. REAL declarations are treated as single precision REAL (REAL(KIND=4)) and COMPLEX declarations are treated as COMPLEX (COMPLEX(KIND=4)).
`real-size 64`	Makes default real and complex variables 8 bytes long. REAL declarations are treated as DOUBLE PRECISION (REAL(KIND=8)) and COMPLEX declarations are treated as DOUBLE COMPLEX (COMPLEX(KIND=8)).
`real-size 128`	Makes default real and complex variables 16 bytes long. REAL declarations are treated as extended precision REAL (REAL(KIND=16)); COMPLEX and DOUBLE COMPLEX declarations are treated as extended precision COMPLEX (COMPLEX(KIND=16)).

These compiler options can affect the result type of intrinsic procedures, such as CMPLX, FLOAT, REAL, SNGL, and AIMAG, which normally produce single-precision REAL or COMPLEX results. To prevent this effect, you must explicitly declare the kind type for arguments of such intrinsic procedures.

For example, if `real-size 64` is specified, the CMPLX intrinsic will produce a result of type DOUBLE COMPLEX (COMPLEX(KIND=8)). To prevent this, you must explicitly declare any real argument to be REAL(KIND=4), and any complex argument to be COMPLEX(KIND=4).

Alternate Options

`real-size 64`	Linux and Mac OS X: `-r8`, `-autodouble` Windows: `/4R8`, `/Qautodouble`
`real-size 128`	Linux and Mac OS X: `-r16` Windows: `/4R16`

recursive

Tells the compiler that all routines should be compiled for possible recursive execution.

IDE Equivalent

Windows: **Code Generation > Enable Recursive Routines**

Linux: None

Mac OS X: **Code Generation > Enable Recursive Routines**

Architectures

IA-32, Intel® 64, IA-64 architectures

Systems: Windows, Linux

Syntax

Linux and Mac OS X:

`-recursive`

`-norecursive`

Windows:

`/recursive`

`/norecursive`

Arguments

None

Default

`norecursive`	Routines are not compiled for possible recursive execution.

Description

This option tells the compiler that all routines should be compiled for possible recursive execution. It sets the `automatic` option.

Alternate Options

None

See Also

-
- `automatic`

reentrancy

Tells the compiler to generate reentrant code to support a multithreaded application.

IDE Equivalent

Windows: **Code Generation > Generate Reentrant Code**

Linux: None

Mac OS X: **Code Generation > Generate Reentrant Code**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-reentrancy` *`keyword`*

`-noreentrancy`

Windows:

`/reentrancy:`*`keyword`*

`/noreentrancy`

Arguments

`keyword`	Specifies details about the program. Possible values are:	
	`none`	Tells the run-time library (RTL) that the program does not rely on threaded or asynchronous reentrancy. The RTL will not guard against such interrupts inside its own critical regions. This is the same as specifying noreentrancy.
	`async`	Tells the run-time library (RTL) that the program may contain asynchronous (AST) handlers that could call the RTL. This causes the RTL to guard against AST interrupts inside its own critical regions.

`threaded`	Tells the run-time library (RTL) that the program is multithreaded, such as programs using the POSIX threads library. This causes the RTL to use thread locking to guard its own critical regions.

Default

`noreentrancy`	The compiler does not generate reentrant code for applications.

Description

This option tells the compiler to generate reentrant code to support a multithreaded application.

If you do not specify a keyword for reentrancy, it is the same as specifying `reentrancy threaded`.

Note that if option threads is specified, it sets option `reentrancy threaded`, since multithreaded code must be reentrant.

Alternate Options

None

See Also

-
- `threads`

RTCu

See check.

S

Causes the compiler to compile to an assembly file only and not link.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-S`

Windows:

`/S`

Arguments

None

Default

OFF	Normal compilation and linking occur.

Description

This option causes the compiler to compile to an assembly file only and not link.

On Linux and Mac OS X systems, the assembly file name has a .s suffix. On Windows systems, the assembly file name has an .asm suffix.

Alternate Options

Linux and Mac OS X: None

Windows: `/Fa`, `/asmfile`

See Also

-
- Fa

safe-cray-ptr, Qsafe-cray-ptr

Tells the compiler that Cray pointers do not alias other variables.*

IDE Equivalent

Windows: **Data > Assume Cray Pointers Do Not Share Memory Locations**

Linux: None

Mac OS X: **Data > Assume Cray Pointers Do Not Share Memory Locations**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-safe-cray-ptr
```

Windows:

```
/Qsafe-cray-ptr
```

Arguments

None

Default

OFF	The compiler assumes that Cray pointers alias other variables.

Description

This option tells the compiler that Cray pointers do not alias (that is, do not specify sharing memory with) other variables.

Alternate Options

None

Example

Consider the following:

```
pointer (pb, b)
pb = getstorage()
do i = 1, n
b(i) = a(i) + 1
enddo
```

By default, the compiler assumes that b and a are aliased. To prevent such an assumption, specify the `-safe-cray-ptr` (Linux and Mac OS X) or `/Qsafe-cray-ptr` (Windows) option, and the compiler will treat b(i) and a(i) as independent of each other.

However, if the variables are intended to be aliased with Cray pointers, using the option produces incorrect results. In the following example, you should not use the option:

```
pointer (pb, b)
pb = loc(a(2))
do i=1, n
b(i) = a(i) +1
enddo
```

save, Qsave

Causes variables to be placed in static memory.

IDE Equivalent

Windows: **Data > Local Variable Storage**

Linux: None

Mac OS X: **Data > Local Variable Storage**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-save`

Windows:

`/Qsave`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`	Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that if option `recursive`, `-openmp` (Linux and Mac OS X), or `/Qopenmp` (Windows) is specified, the default is `-automatic` (Linux) or `/Qauto` (Windows).

Description

This option saves all variables in static allocation except local variables within a recursive routine and variables declared as AUTOMATIC.

If you want all local, non-SAVEd variables to be allocated to the run-time stack, specify option `automatic`.

Alternate Options

Linux and Mac OS X: `-noautomatic`, `-noauto`

Windows: `/noautomatic`, `/noauto`, `/4Na`

See Also

-
-
- `automatic`
- `auto_scalar`

save-temps, Qsave-temps

Tells the compiler to save intermediate files created during compilation.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-save-temps`

`-no-save-temps`

Windows:

`/Qsave-temps`

`/Qsave-temps-`

Arguments

None

Default

Linux and Mac OS X: `-no-save-temps` Windows: .obj files are saved	On Linux and Mac OS X systems, the compiler deletes intermediate files after compilation is completed. On Windows systems, the compiler saves only intermediate object files after compilation is completed.

Description

This option tells the compiler to save intermediate files created during compilation. The names of the files saved are based on the name of the source file; the files are saved in the current working directory.

If `-save-temps` or `/Qsave-temps` is specified, the following occurs:

- The object .o file (Linux and Mac OS X) or .obj file (Windows) is saved.
- The assembler .s file (Linux and Mac OS X) or .asm file (Windows) is saved if you specified -use-asm (Linux or Mac OS X) or /Quse-asm (Windows).
- The .i or .i90 file is saved if the fpp preprocessor is invoked.

If `-no-save-temps` is specified on Linux or Mac OS X systems, the following occurs:

- The .o file is put into `/tmp` and deleted after calling `ld`.
- The preprocessed file is not saved after it has been used by the compiler.

If `/Qsave-temps-` is specified on Windows systems, the following occurs:

- The .obj file is not saved after the linker step.
- The preprocessed file is not saved after it has been used by the compiler.

NOTE. This option only saves intermediate files that are normally created during compilation.

Alternate Options

None

Example

If you compile program `my_foo.F` on a Linux or Mac OS X system and you specify option `-save-temps` and option `-use-asm`, the compilation will produce `files my_foo.o`, `my_foo.s`, and `my_foo.i`.

If you compile program `my_foo.fpp` on a Windows system and you specif option `/Qsave-temps` and option `/Quse-asm`, the compilation will produce `files my_foo.obj`, `my_foo.asm`, and `my_foo.i`.

scalar-rep, Qscalar-rep

Enables scalar replacement performed during loop transformation.

IDE Equivalent

None

Architectures

IA-32 architecture

Syntax

Linux and Mac OS X:

`-scalar-rep`

`-no-scalar-rep`

Windows:

`/Qscalar-rep`

`/Qscalar-rep-`

Arguments

None

Default

`-no-scalar-rep` or `/Qscalar-rep-`	Scalar replacement is not performed during loop transformation.

Description

This option enables scalar replacement performed during loop transformation. To use this option, you must also specify `O3`.

Alternate Options

None

See Also

-
-
- O

shared

Tells the compiler to produce a dynamic shared object instead of an executable.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-shared`

Mac OS X:

None

Windows:

None

Arguments

None

Default

OFF	The compiler produces an executable.

Description

This option tells the compiler to produce a dynamic shared object (DSO) instead of an executable. This includes linking in all libraries dynamically and passing `-shared` to the linker.

On systems using IA-32 architecture and Intel® 64 architecture, you must specify option `fpic` for the compilation of each object file you want to include in the shared library.

Alternate Options

None

See Also

-
- `dynamiclib`
- `fpic`

shared-intel

Causes Intel-provided libraries to be linked in dynamically.

IDE Equivalent

Windows: None

Linux: None

Mac OS X: **Run-Time > Intel Runtime Libraries**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-shared-intel`

Windows:

`None`

Arguments

None

Default

OFF	Intel libraries are linked in statically, with the exception of libguide on Linux* and Mac OS* X systems, where it is linked in dynamically.

Description

This option causes Intel-provided libraries to be linked in dynamically. It is the opposite of `-static-intel`.

NOTE. On Mac OS X systems, when you set "Intel Runtime Libraries" to "Dynamic", you must also set the DYLD_LIBRARY_PATH environment variable within Xcode or an error will be displayed.

Alternate Options

Linux and Mac OS X: `-i-dynamic` (this is a deprecated option)

Windows: None

See Also

-
- `static-intel`

shared-libgcc

Links the GNU `libgcc` *library dynamically.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-shared-libgcc`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

`-shared-libgcc`	The compiler links the `libgcc` library dynamically.

Description

This option links the GNU `libgcc` library dynamically. It is the opposite of option `static-libgcc`.

This option is useful when you want to override the default behavior of the `static` option, which causes all libraries to be linked statically.

Alternate Options

None

See Also

-
- static-libgcc

source

Tells the compiler to compile the file as a Fortran source file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/source:`*`file`*

Arguments

`file`	Is the name of the file.

Default

OFF	Files that do not end in standard Fortran file extensions are not compiled as Fortran files.

Description

This option tells the compiler to compile the file as a Fortran source file.

This option is useful when you have a Fortran file with a nonstandard file extension (that is, not one of .F, .FOR, or .F90).

This option assumes the file specified uses fixed source form. If the file uses free source form, you must also specify option `free`.

Alternate Options

Linux and Mac OS X: `-Tf file`

Windows: `/Tf file`

See Also

-
- `extfor`
- `free`

sox, Qsox

Tells the compiler to save the compilation options and version number in the Linux OS executable or the Windows* OS object file.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

```
-sox
-no-sox
```

Mac OS X:

```
None
```

Windows:

```
/Qsox
/Qsox-
```

Arguments

None

Default

`-no-sox` or `/Qsox-`	The compiler does not save the compiler options and version number in the executable.

Description

Tells the compiler to save the compilation options and version number in the Linux* OS executable or the Windows* OS object file.

On Linux systems, the size of the executable on disk is increased slightly by the inclusion of these infotmation strings.

This option forces the compiler to embed in each object file or assembly output a string that contains information about the compiler version and compilation options for each source file that has been compiled.

On Windows systems, the information stays in the object file. On Linux systems, when you link the object files into an executable file, the linker places each of the information strings into the header of the executable. It is then possible to use a tool, such as a strings utility, to determine what options were used to build the executable file.

If `-no-sox` or `/Qsox-` is specified, this extra information is not put into the object or assembly output generated by the compiler.

Alternate Options

None

stand

Tells the compiler to issue compile-time messages for nonstandard language elements.

IDE Equivalent

Windows: **Compilation Diagnostics > Warn For Nonstandard Fortran**

Linux: None

Mac OS X: **Compiler Diagnostics > Warn For Nonstandard Fortran**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-stand [keyword]`

`-nostand`

Windows:

`/stand[:keyword]`

`/nostand`

Arguments

keyword	Specifies the language to use as the standard. Possible values are:
`none`	Issue no messages for nonstandard language elements.
`f90`	Issue messages for language elements that are not standard in Fortran 90.
`f95`	Issue messages for language elements that are not standard in Fortran 95.
`f03`	Issue messages for language elements that are not standard in Fortran 2003.

Default

`nostand`	The compiler issues no messages for nonstandard language elements.

Description

This option tells the compiler to issue compile-time messages for nonstandard language elements.

If you do not specify a keyword for `stand`, it is the same as specifying `stand f95`.

Option	Description
`stand none`	Tells the compiler to issue no messages for nonstandard language elements. This is the same as specifying `nostand`.

Option	Description
`stand f90`	Tells the compiler to issue messages for language elements that are not standard in Fortran 90.
`stand f95`	Tells the compiler to issue messages for language elements that are not standard in Fortran 95.
`stand f03`	Tells the compiler to issue messages for language elements that are not standard in Fortran 2003. This option is set if you specify `warn stderrors`.

Alternate Options

`stand none`	Linux and Mac OS X: `-nostand` Windows: `/nostand`, `/4Ns`
`stand f90`	Linux and Mac OS X: `-std90` Windows: `/4Ys`
`stand f95`	Linux and Mac OS X: `-std95` Windows: None
`stand f03`	Linux and Mac OS X: `-std03`, `-stand`, `-std` Windows: `/stand`

See Also

-
- `warn stderrors`

static

Prevents linking with shared libraries.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-static`

Mac OS X:

`None`

Windows:

`/static`

Arguments

None

Default

`static`	The compiler does not link with shared libraries.

Description

This option prevents linking with shared libraries. It causes the executable to link all libraries statically.

Alternate Options

None

staticlib

Invokes the `libtool` *command to generate static libraries.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux:

`None`

Mac OS X:

`-staticlib`

Windows:

`None`

Arguments

None

Default

OFF	The compiler produces an executable.

Description

This option invokes the `libtool` command to generate static libraries.

When passed this option, the compiler uses the `libtool` command to produce a static library instead of an executable when linking.

To build dynamic libraries, you should specify option `-dynamiclib` or `libtool -dynamic <objects>`.

Alternate Options

None

See Also

-
- dynamiclib

static-intel

Causes Intel-provided libraries to be linked in statically.

IDE Equivalent

Windows: None

Linux: None

Mac OS X: **Run-Time > Intel Runtime Libraries**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-static-intel`

Windows:

`None`

Arguments

None

Default

OFF	Intel libraries are linked in statically, with the exception of libguide, which is linked in dynamically.

Description

This option causes Intel-provided libraries to be linked in statically. It is the opposite of `-shared-intel`.

Alternate Options

Linux and Mac OS X: `i-static` (this is a deprecated option)

Windows: None

See Also

-
- `shared-intel`

static-libgcc

Links the GNU `libgcc` *library statically.*

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-static-libgcc`

Mac OS X:

`None`

Windows:

`None`

Arguments

None

Default

OFF	DEFAULT_DESC

Description

This option links the GNU `libgcc` library statically. It is the opposite of option `libgcc`.

This option is useful when you want to override the default behavior of the `libgcc` option, which causes all libraries to be linked statically.

Alternate Options

None

syntax-only

Tells the compiler to check only for correct syntax.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-syntax-only
```

Windows:

```
/syntax-only
```

Arguments

None

Default

OFF	Normal compilation is performed.

Description

This option tells the compiler to check only for correct syntax. It lets you do a quick syntax check of your source file.

Compilation stops after the source file has been parsed. No code is generated, no object file is produced, and some error checking done by the optimizer is bypassed.

Warnings and messages appear on `stderr`.

Alternate Options

Linux: `-y, -fsyntax-only, -syntax` (this is a deprecated option)

Mac OS X: `-y, -fsyntax-only`

Windows: `/Zs`

T

Tells the linker to read link commands from a file.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-T`*`file`*

Mac OS X:

None

Windows:

None

Arguments

file	Is the name of the file.

Default

OFF	The linker does not read link commands from a file.

Description

This option tells the linker to read link commands from a file.

Alternate Options

None

tcheck, Qtcheck

Enables analysis of threaded applications.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

-tcheck

Mac OS X:

None

Windows:

`/Qtcheck`

Arguments

None

Default

OFF	Threaded applications are not instrumented by the compiler for analysis by Intel® Thread Checker.

Description

This option enables analysis of threaded applications.

To use this option, you must have Intel® Thread Checker installed, which is one of the Intel® Threading Analysis Tools. If you do not have this tool installed, the compilation will fail. Remove the `-tcheck` (Linux) or `/Qtcheck` (Windows) option from the command line and recompile.

For more information about Intel® Thread Checker (including an evaluation copy), open the page associated with threading tools at Intel® Software Development Products.

Alternate Options

None

tcollect, Qtcollect

Inserts instrumentation probes calling the Intel® Trace Collector API.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tcollect[`*`lib`*`]`

Mac OS X:

None

Windows:

/Qtcollect[:*lib*]

Arguments

lib	Is one of the Intel® Trace Collector libraries; for example, VT, VTcs, VTmc, or VTfs. If you do not specify *lib*, the default library is VT.

Default

OFF	Instrumentation probes are not inserted into compiled applications.

Description

This option inserts instrumentation probes calling the Intel® Trace Collector API. To use this option, you must have the Intel® Trace Collector installed and set up through one of its set-up scripts. This tool is a component of the Intel® Trace Analyzer and Collector.

This option provides a flexible and convenient way of instrumenting functions of a compiled application. For every function, the entry and exit points are instrumented at compile time to let the Intel® Trace Collector record functions beyond the default MPI calls. For non-MPI applications (for example, threaded or serial), you must ensure that the Intel® Trace Collector is properly initialized (VT_initialize/VT_init).

CAUTION. Be careful with full instrumentation because this feature can produce very large trace files.

For more details, see the Intel® Trace Collector User Guide.

Alternate Options

None

See Also

-
-

- tcollect-filter, Qtcollect-filter

tcollect-filter, Qtcollect-filter

Lets you enable or disable the instrumentation of specified functions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tcollect-filter` *file*

Mac OS X:

`None`

Windows:

`/Qtcollect-filter:`*file*

Arguments

file	Is a configuration file that lists filters, one per line. Each filter consists of a regular expression string and a switch. Strings with leading or trailing white spaces must be quoted. Other strings do not have to be quoted. The switch value can be ON, on, OFF, or off.

Default

OFF	Functions are not instrumented. However, if option `-tcollect` (Linux) or `/Qtcollect` (Windows) is specified, the filter setting is ".* ON" and all functions get instrumented.

Description

This option lets you enable or disable the instrumentation of specified functions.

During instrumentation, the regular expressions in the file are matched against the function names. The switch specifies whether matching functions are to be instrumented or not. Multiple filters are evaluated from top to bottom with increasing precedence.

The names of the functions to match against are formatted as follows:

- The source file name is followed by a colon-separated function name. Source file names should contain the full path, if available. For example:
  `/home/joe/src/file.f:FOO_bar`
- Classes and function names are separated by double colons. For example:
  `/home/joe/src/file.fpp:app::foo::bar`

You can use option `-opt-report` (Linux) or `/Qopt-report` (Windows) to get a full list of file and function names that the compiler recognizes from the compilation unit. This list can be used as the basis for filtering in the configuration file.

To use this option, you must have the Intel® Trace Collector installed and set up through one of its set-up scripts. This tool is a component of the Intel® Trace Analyzer and Collector.

For more details, see the Intel® Trace Collector User Guide.

Alternate Options

None

Consider the following filters in a configuration file:

```
'.*' OFF '.*vector.*' ON
```

The above will cause instrumentation of only those functions having the string 'vector' in their names. No other function will be instrumented. Note that reversing the order of the two lines will prevent instrumentation of all functions.

To get a list of the file or routine strings that can be matched by the regular expression filters, generate an optimization report with tcollect information. For example:

```
Windows OS: ifort /Qtcollect /Qopt-report /Qopt-report-phase tcollect

Linux OS: ifort -tcollect -opt-report -opt-report-phase tcollect
```

See Also

-
-
- tcollect, Qtcollect

Tf

See source.

threads

Tells the linker to search for unresolved references in a multithreaded run-time library.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-threads`

`-nothreads`

Windows:

`/threads`

`/nothreads`

Arguments

None

Default

Systems using Intel® 64 architecture: `threads` Systems using IA-32 architecture and IA-64 architecture: `nothreads`	On systems using IA-32 architecture and IA-64 architecture, the linker does not search for unresolved references in a mutithreaded run-time library. On systems using Intel® 64 architectures, it does.

Description

This option tells the linker to search for unresolved references in a multithreaded run-time library.

This option sets option `reentrancy threaded`.

Windows systems: The following table shows which options to specify for a multithreaded run-time library.

Type of Library	Options Required	Alternate Option
Multithreaded	`/libs:static` `/threads`	`/MT`

Debug multithreaded	`/libs:static`
	`/threads`
	`/dbglibs`
		`/MTd`

Multithreaded DLLs	`/libs:dll` `/threads`	`/MD`

Multithreaded debug DLLs	`/libs:dll`
	`/threads`
	`/dbglibs`
		`/MDd`

Alternate Options

None

See Also

- Building Applications: Specifying Consistent Library Types; Programming with Mixed Languages Overview

tprofile, Qtprofile

Generates instrumentation to analyze multi-threading performance.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux:

`-tprofile`

Mac OS X:

`None`

Windows:

`/Qtprofile`

Arguments

None

Default

OFF	Instrumentation is not generated by the compiler for analysis by Intel® Thread Profiler.

Description

This option generates instrumentation to analyze multi-threading performance.

To use this option, you must have Intel® Thread Profiler installed, which is one of the Intel® Threading Analysis Tools. If you do not have this tool installed, the compilation will fail. Remove the `-tprofile` (Linux) or `/Qtprofile` (Windows) option from the command line and recompile.

For more information about Intel® Thread Profiler (including an evaluation copy), open the page associated with threading tools at Intel® Software Development Products.

Alternate Options

None

traceback

Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.

IDE Equivalent

Windows: **Run-time > Generate Traceback Information**

Linux: None

Mac OS X: **Run-time > Generate Traceback Information**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-traceback`

`-notraceback`

Windows:

`/traceback`

`/notraceback`

Arguments

None

Default

`notraceback`	No extra information is generated in the object file to produce traceback information.

Description

This option tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.

When the severe error occurs, source file, routine name, and line number correlation information is displayed along with call stack hexadecimal addresses (program counter trace).

Note that when a severe error occurs, advanced users can also locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when the error occurs.

This option increases the size of the executable program, but has no impact on run-time execution speeds.

It functions independently of the debug option.

On Windows systems, `traceback` sets the `/Oy-` option, which forces the compiler to use EBP as the stack frame pointer.

On Windows systems, the linker places the traceback information in the executable image, in a section named ".trace". To see which sections are in an image, use the command:

```
link -dump -summary your_app_name.exe
```

To see more detailed information, use the command:

```
link -dump -headers your_app_name.exe
```

On Windows systems, when requesting traceback, you must set Enable Incremental Linking in the VS .NET* IDE Linker Options to No. On systems using IA-32 architecture and Intel® 64 architecture, you must also set Omit Frame Pointers (the `/Oy` option) in the Optimization Options to "No."

On Linux systems, to display the section headers in the image (including the header for the .trace section, if any), use the command:

```
objdump -h your_app_name.exe
```

On Mac OS X systems, to display the section headers in the image, use the command:

```
otool -l your_app_name.exe
```

Alternate Options

None

tune

Determines the version of the architecture for which the compiler generates instructions.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-tune keyword`

Windows:

`/tune:keyword`

Arguments

keyword	Specifies the processor type. Possible values are:	
	`pn1`	Optimizes for the Intel® Pentium® processor.
	`pn2`	Optimizes for the Intel® Pentium® Pro, Intel® Pentium® II, and Intel® Pentium® III processors.
	`pn3`	Optimizes for the Intel® Pentium® Pro, Intel® Pentium® II, and Intel® Pentium® III processors. This is the same as specifying `pn2`.
	`pn4`	Optimizes for the Intel® Pentium® 4 processor.

Default

`pn4`	The compiler optimizes for the Intel® Pentium® 4 processor.

Description

This option determines the version of the architecture for which the compiler generates instructions.

On systems using Intel® 64 architecture, only *keyword* `pn4` is valid.

Alternate Options

None

u (Linux* and Mac OS* X)

See warn.

u (Windows*)

Undefines all previously defined preprocessor values.

IDE Equivalent

Windows: **Preprocessor > Undefine All Preprocessor Definitions**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
None
```

Windows:

```
/u
```

Arguments

None

Default

OFF	Defined preprocessor values are in effect until they are undefined.

Description

This option undefines all previously defined preprocessor values.

To undefine specific preprocessor values, use the `/U` option.

Alternate Options

None

See Also

-
- U

U

Undefines any definition currently in effect for the specified symbol.

IDE Equivalent

Windows: **Preprocessor > Undefine Preprocessor Definitions**

Linux: None

Mac OS X: **Preprocessor > Undefine Preprocessor Definitions**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

-Uname

Windows:

/Uname

Arguments

name	Is the name of the symbol to be undefined.

Default

OFF	Symbol definitions are in effect until they are undefined.

Description

This option undefines any definition currently in effect for the specified symbol.

On Windows systems, use the `/u` option to undefine all previously defined preprocessor values.

Alternate Options

Linux and Mac OS X: None

Windows: `/undefine:`*`name`*

See Also

-
- `u` (Windows)

undefine

See U.

unroll, Qunroll

Tells the compiler the maximum number of times to unroll loops.

IDE Equivalent

Windows: **Optimization > Loop Unroll Count**

Linux: None

Mac OS X: **Optimization > Loop Unroll Count**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-unroll[=`*`n`*`]`

Windows:

`/Qunroll[:`*`n`*`]`

Arguments

n	Is the maximum number of times a loop can be unrolled. To disable loop enrolling, specify 0. On systems using IA-64 architecture, you can only specify a value of 0.

Default

`-unroll` or `/Qunroll`	The compiler uses default heuristics when unrolling loops.

Description

This option tells the compiler the maximum number of times to unroll loops.

If you do not specify *n*, the optimizer determines how many times loops can be unrolled.

Alternate Options

Linux and Mac OS X: `-funroll-loops`

Windows: `/unroll`

See Also

-
-

Optimizing Applications: Loop Unrolling

unroll-aggressive, Qunroll-aggressive

Determines whether the compiler uses more aggressive unrolling for certain loops.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-unroll-aggressive`

`-no-unroll-aggressive`

Windows:

`/Qunroll-aggressive`

`/Qunroll-aggressive-`

Arguments

None

Default

`-no-unroll-aggressive` or `/Qunroll-aggressive-`	The compiler uses default heuristics when unrolling loops.

Description

This option determines whether the compiler uses more aggressive unrolling for certain loops. The positive form of the option may improve performance.

On IA-32 architecture and Intel® 64 architecture, this option enables aggressive, complete unrolling for loops with small constant trip counts.

On IA-64 architecture, this option enables additional complete unrolling for loops that have multiple exits or outer loops that have a small constant trip count.

Alternate Options

None

uppercase, Quppercase

See names.

us

See assume.

use-asm, Quse-asm

Tells the compiler to produce objects through the assembler.

IDE Equivalent

None

Architectures

`-use-asm`: IA-32 architecture, Intel® 64 architecture, IA-64 architecture

`/Quse-asm`: IA-64 architecture

Syntax

Linux and Mac OS X:

`-use-asm`

`-no-use-asm`

Windows:

`/Quse-asm`

`/Quse-asm-`

Arguments

None

Default

`-no-use-asm` or `/Quse-asm-`	The compiler produces objects directly.

Description

This option tells the compiler to produce objects through the assembler.

Alternate Options

None

v

Specifies that driver tool commands should be displayed and executed.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-v[file]`

Windows:

`None`

Arguments

file	Is the name of a file.

Default

OFF	No tool commands are shown.

Description

This option specifies that driver tool commands should be displayed and executed.

If you use this option without specifying a file name, the compiler displays only the version of the compiler.

If you want to display processing information (pass information and source file names), specify option `watch:all`.

Alternate Options

Linux and Mac OS X: `-watch cmd`

Windows: `/watch:cmd`

See Also

-
- `dryrun`
- `watch`

V (Linux* and Mac OS* X)

See logo

V (Windows*)

See bintext.

vec, Qvec

Enables or disables vectorization and transformations enabled for vectorization.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

```
-vec
-no-vec
```

Windows:

```
/Qvec
```

/Qvec-

Arguments

None

Default

-vec or/Qvec	Vectorization is enabled.

Description

This option enables or disables vectorization and transformations enabled for vectorization.

To disable vectorization and transformations enabled for vectorization, specify -no-vec (Linux and Mac OS X) or /Qvec- (Windows).

Alternate Options

None

See Also

-
-
- ax, Qax
- x, Qx
- vec-report, Qvec-report
- vec-guard-write, Qvec-guard-write
- vec-threshold, Qvec-threshold

vec-guard-write, Qvec-guard-write

Tells the compiler to perform a conditional check in a vectorized loop.

IDE Equivalent

None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-vec-guard-write`

`-no-vec-guard-write`

Windows:

`/Qvec-guard-write`

`/Qvec-guard-write-`

Arguments

None

Default

`-no-vec-guard-write` or `/Qvec-guard-write-`	The compiler uses default heuristics when checking vectorized loops.

Description

This option tells the compiler to perform a conditional check in a vectorized loop. This checking avoids unnecessary stores and may improve performance.

Alternate Options

None

vec-report, Qvec-report

Controls the diagnostic information reported by the vectorizer.

IDE Equivalent

Windows: **Compilation Diagnostics > Vectorizer Diagnostic Level**

Linux: None

Mac OS X: **Diagnostics > Vectorizer Diagnostic Report**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-vec-report[n]`

Windows:

`/Qvec-report[n]`

Arguments

n	Is a value denoting which diagnostic messages to report. Possible values are:
0	Tells the vectorizer to report no diagnostic information.
1	Tells the vectorizer to report on vectorized loops.
2	Tells the vectorizer to report on vectorized and non-vectorized loops.
3	Tells the vectorizer to report on vectorized and non-vectorized loops and any proven or assumed data dependences.
4	Tells the vectorizer to report on non-vectorized loops.
5	Tells the vectorizer to report on non-vectorized loops and the reason why they were not vectorized.

Default

`-vec-report1` or `/Qvec-report1`	If the vectorizer has been enabled and you do not specify *n*, the compiler reports diagnostics on vectorized loops. If you do not specify the option on the command line, the default is to display no messages.

Description

This option controls the diagnostic information reported by the vectorizer. The vectorizer report is sent to stdout.

If you do not specify *n*, it is the same as specifying `-vec-report1` (Linux and Mac OS X) or `/Qvec-report1` (Windows).

The vectorizer is enabled when certain compiler options are specified, such as option `-ax` or `-x` (Linux and Mac OS X), option `/Qax` or `/Qx` (Windows), option `-arch SSE` or `-arch SSE2` (Linux and Mac OS X), option `/architecture:SSE` or `/architecture:SSE2` (Windows).

If this option is specified from within the IDE, the report is included in the build log if the Generate Build Logs option is selected.

Alternate Options

None

vec-threshold, Qvec-threshold

Sets a threshold for the vectorization of loops.

IDE Equivalent

Windows: **Optimization > Threshold For Vectorization**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

`-vec-threshold[`*n*`]`

Windows:

`/Qvec-threshold[[:]`*n*`]`

Arguments

n	Is an integer whose value is the threshold for the vectorization of loops. Possible values are 0 through 100. If *n* is 0, loops get vectorized always, regardless of computation work volume.

If *n* is 100, loops get vectorized when performance gains are predicted based on the compiler analysis data. Loops get vectorized only if profitable vector-level parallel execution is almost certain.
The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, *n*=50 directs the compiler to vectorize only if there is a 50% probability of the code speeding up if executed in vector form.

Default

`-vec-threshold100` or `/Qvec-threshold100`	Loops get vectorized only if profitable vector-level parallel execution is almost certain. This is also the default if you do not specify *n*.

Description

This option sets a threshold for the vectorization of loops based on the probability of profitable execution of the vectorized loop in parallel.

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

Alternate Options

None

vms

Causes the run-time system to behave like HP Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).*

IDE Equivalent

Windows: **Compatibility > Enable VMS Compatibility**

Linux: None

Mac OS X: **Compatibility > Enable VMS Compatibility**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-vms`

`-novms`

Windows:

`/vms`

`/novms`

Arguments

None

Default

`novms` The run-time system follows default Intel® Fortran behavior.

Description

This option causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).

It affects the following language features:

- Certain defaults

  In the absence of other options, `vms` sets the defaults as `check format` and `check output_conversion`.

- Alignment

  Option `vms` does not affect the alignment of fields in records or items in common blocks. For compatibility with HP Fortran on OpenVMS systems, use `align norecords` to pack fields of records on the next byte boundary.

- Carriage control default

  If option `vms` and option `ccdefault default` are specified, carriage control defaults to FORTRAN if the file is formatted and the unit is connected to a terminal.

- INCLUDE qualifiers

  /LIST and /NOLIST are recognized at the end of the file name in an INCLUDE statement at compile time. If the file name in the INCLUDE statement does not specify the complete path, the path used is the current directory. Note that if vms is not specified, the path used is the directory where the file that contains the INCLUDE statement resides.

- Quotation mark character

  A quotation mark (") character is recognized as starting an octal constant ("0..7) instead of a character literal ("...").

- Deleted records in relative files

  When a record in a relative file is deleted, the first byte of that record is set to a known character (currently '@'). Attempts to read that record later result in ATTACCNON errors. The rest of the record (the whole record, if vms is not specified) is set to nulls for unformatted files and spaces for formatted files.

- ENDFILE records

  When an ENDFILE is performed on a sequential unit, an actual 1-byte record containing a Ctrl/Z is written to the file. If vms is not specified, an internal ENDFILE flag is set and the file is truncated. The vms option does not affect ENDFILE on relative files: these files are truncated.

- Implied logical unit numbers

  The vms option enables Intel Fortran to recognize certain environment variables at run time for ACCEPT, PRINT, and TYPE statements and for READ and WRITE statements that do not specify a unit number (such as READ (*,1000)).

- Treatment of blanks in input

  The vms option causes the defaults for the keyword BLANK in OPEN statements to become 'NULL' for an explicit OPEN and 'ZERO' for an implicit OPEN of an external or internal file.

- OPEN statement effects

  Carriage control defaults to FORTRAN if the file is formatted, and the unit is connected to a terminal. Otherwise, carriage control defaults to LIST. The vms option affects the record length for direct access and relative organization files. The buffer size is increased by 1 to accommodate the deleted record character.

- Reading deleted records and ENDFILE records

The run-time direct access READ routine checks the first byte of the retrieved record. If this byte is '@' or NULL ("\0"), then an ATTACCNON error is returned. The run-time sequential access READ routine checks to see if the record it just read is one byte long and contains a Ctrl/Z. If this is true, it returns EOF.

Alternate Options

Linux and Mac OS X: None

Windows: `/Qvms`

w

See keywords `none` *and* `nogeneral` *in warn*

W0, W1

See warn.

W0, W1

See warn.

Wa

Passes options to the assembler for processing.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Wa,option1[,option2,...]`

Windows:

`None`

Arguments

option	Is an assembler option. This option is not processed by the driver and is directly passed to the assembler.

Default

OFF	No options are passed to the assembler.

Description

This option passes one or more options to the assembler for processing. If the assembler is not invoked, these options are ignored.

Alternate Options

None

warn

Specifies diagnostic messages to be issued by the compiler.

IDE Equivalent

Windows: **General > Compile Time Diagnostics** (`/warn:all, /warn:none`)

Compilation Diagnostics > Treat Warnings as Errors (`/warn:[no]errors`)

Compilation Diagnostics > Treat Fortran Standard Warnings as Errors (`/warn:[no]stderrors`)

Compilation Diagnostics > Compile Time Diagnostics (`/warn:all, /warn:none`)

Compilation Diagnostics > Warn for Undeclared Symbols (`/warn:[no]declarations`)

Compilation Diagnostics > Warn for Unused Variables (`/warn:[no]unused`)

Compilation Diagnostics > Warn When Removing %LOC (`/warn:[no]ignore_loc`)

Compilation Diagnostics > Warn When Truncating Source Line (`/warn:[no]truncated_source`)

Compilation Diagnostics > Warn for Unaligned Data (`/warn:[no]alignments`)

Compilation Diagnostics > Warn for Uncalled Statement Function (`/warn:[no]uncalled`)

Compilation Diagnostics > Suppress Usage Messages (`/warn:[no]usage`)

Compilation Diagnostics > Check Routine Interfaces (`/warn:[no]interfaces`)

Linux: None

Mac OS X: **General > Compile Time Diagnostics** (`-warn all, -warn none`)

Compiler Diagnostics > Warn For Unaligned Data (`-warn [no]alignments`)

Compiler Diagnostics > Warn For Undeclared Symbols (`-warn [no]declarations`)

Compiler Diagnostics > Treat Warnings as Errors (`-warn error`)

Compiler Diagnostics > Warn When Removing %LOC (`-warn [no]ignore_loc`)

Compiler Diagnostics > Check Routine Interfaces (`-warn [no]interfaces`)

Compiler Diagnostics > Treat Fortran Standard Warnings As Errors (`-warn [no]stderrors`)

Compiler Diagnostics > Warn When Truncating Source Line (`-warn [no]truncated_source`)

Compiler Diagnostics > Warn For Uncalled Routine (`-warn [no]uncalled`)

Compiler Diagnostics > Warn For Unused Variables (`-warn [no]unused`)

Compiler Diagnostics > Suppress Usage Messages (`-warn [no]usage`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-warn [`*keyword*`]`

`-nowarn`

Windows:

`/warn[:keyword]`

`/nowarn`

Arguments

keyword Specifies the diagnostic messages to be issued. Possible values are:

`none`	Disables all warning messages.
`[no]alignments`	Determines whether warnings occur for data that is not naturally aligned.
`[no]declarations`	Determines whether warnings occur for any undeclared symbols.
`[no]errors`	Determines whether warnings are changed to errors.
`[no]general`	Determines whether warning messages and informational messages are issued by the compiler.
`[no]ignore_loc`	Determines whether warnings occur when `%LOC` is stripped from an actual argument.
`[no]interfaces`	Determines whether the compiler checks the interfaces of all SUBROUTINEs called and FUNCTIONs invoked in your compilation against an external set of interface blocks.
`[no]stderrors`	Determines whether warnings about Fortran standard violations are changed to errors.
`[no]truncated_source`	Determines whether warnings occur when source exceeds the maximum column width in fixed-format files.
`[no]uncalled`	Determines whether warnings occur when a statement function is never called
`[no]unused`	Determines whether warnings occur for declared variables that are never used.

[no]usage	Determines whether warnings occur for questionable programming practices.
all	Enables all warning messages except errors and stderrors.

Default

alignments	Warnings are issued about data that is not naturally aligned.
general	All information-level and warning-level messages are enabled.
usage	Warnings are issued for questionable programming practices.
nodeclarations	No errors are issued for undeclared symbols.
noerrors	Warning-level messages are not changed to error-level messages.
noignore_loc	No warnings are issued when %LOC is stripped from an argument.
nointerfaces	The compiler does not check interfaces of SUBROUTINEs called and FUNCTIONs invoked in your compilation against an external set of interface blocks.
nostderrors	Warning-level messages about Fortran standards violations are not changed to error-level messages.
notruncated_source	No warnings are issued when source exceeds the maximum column width in fixed-format files.
nouncalled	No warnings are issued when a statement function is not called.
nounused	No warnings are issued for variables that are declared but never used.

Description

This option specifies the diagnostic messages to be issued by the compiler.

Option	Description
warn none	Disables all warning messages. This is the same as specifying nowarn.
warn noalignments	Disables warnings about data that is not naturally aligned.
warn declarations	Enables error messages about any undeclared symbols. This option makes the default data type of a variable undefined (IMPLICIT NONE) rather than using the implicit Fortran rules.

Option	Description
warn errors	Tells the compiler to change all warning-level messages to error-level messages; this includes warnings about Fortran standards violations.
warn nogeneral	Disables all informational-level and warning-level diagnostic messages.
warn ignore_loc	Enables warnings when %LOC is stripped from an actual argument.
warn interfaces	Tells the compiler to check the interfaces of all SUBROUTINEs called and FUNCTIONs invoked in your compilation against a set of interface blocks stored separately from the source being compiled. The compiler generates a compile-time message if the interface used to invoke a routine does not match the interface defined in a .mod file external to the source (that is, in a .mod generated by option gen-interfaces as opposed to a .mod file USEd in the source). The compiler looks for these .mods in the current directory or in the directory specified by the include (-I) or -module option. warn interfaces turns on the option gen-interfaces by default. You can explicitly turn it off with /gen-interfaces- on Windows and -no-gen-interfaces on Linux and Mac OS X.
warn stderrors	Tells the compiler to change all warning-level messages about Fortran standards violations to error-level messages. This option sets the std03 option (Fortran 2003 standard). If you want Fortran 95 standards violations to become errors, you must specify options warn stderrors and std95.
warn truncated_source	Enables warnings when a source line exceeds the maximum column width in fixed-format source files. The maximum column width for fixed-format files is 72, 80, or 132, depending on the setting of the extend-source option. The warn truncated_source option has no effect on truncation; lines that exceed the maximum column width are always truncated. This option does not apply to free-format source files.
warn uncalled	Enables warnings when a statement function is never called.
warn unused	Enables warnings for variables that are declared but never used.

Option	Description
`warn nousage`	Disables warnings about questionable programming practices. Questionable programming practices, although allowed, often are the result of programming errors; for example: a continued character or Hollerith literal whose first part ends before the statement field and appears to end with trailing spaces. Note that the `/pad-source` option can prevent this error.
`warn all`	This is the same as specifying `warn`. This option does not set options `warn errors` or `warn stderrors`. To enable all the additional checking to be performed and force the severity of the diagnostic messages to be severe enough to not generate an object file, specify `warn all warn errors` or `warn all warn stderrors`. On Windows systems: In the Property Pages, **Custom** means that diagnostics will be specified on an individual basis.

Alternate Options

`warn none`	Linux and Mac OS X: `-nowarn`, `-w`, `-W0`, `-warn nogeneral` Windows: `/nowarn`,`/w`, `/W0`, `/warn:nogeneral`
`warn declarations`	Linux and Mac OS X: `-implicitnone`, `-u` Windows: `/4Yd`
`warn nodeclarations`	Linux and Mac OS X: None Windows: `/4Nd`
`warn general`	Linux and Mac OS X: `-W1` Windows: `/W1`
`warn nogeneral`	Linux and Mac OS X: `-W0`, `-w`, `-nowarn`, `-warn none` Windows: `/W0, /w, /nowarn, /warn:none`
`warn stderrors`	Linux and Mac OS X: `-e90`, `-e95`, `-e03` Windows: None
`warn nousage`	Linux and Mac OS X: `-cm` Windows: `/cm`
`warn all`	Linux and Mac OS X: `-warn` Windows: `/warn`

watch

Tells the compiler to display certain information to the console output window.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-watch [keyword]`

`-nowatch`

Windows:

`/watch[:keyword]`

`/nowatch`

Arguments

keyword Determines what information is displayed. Possible values are:

`none`	Disables `cmd` and `source`.
`[no]cmd`	Determines whether driver tool commands are displayed and executed.
`[no]source`	Determines whether the name of the file being compiled is displayed.
`all`	Enables `cmd` and `source`.

Default

`nowatch` Pass information and source file names are not displayed to the console output window.

Description

Tells the compiler to display processing information (pass information and source file names) to the console output window.

Option	Description
`watch none`	Tells the compiler to not display pass information and source file names to the console output window. This is the same as specifying `nowatch`.
`watch cmd`	Tells the compiler to display and execute driver tool commands.
`watch source`	Tells the compiler to display the name of the file being compiled.
`watch all`	Tells the compiler to display pass information and source file names to the console output window. This is the same as specifying `watch` with no *`keyword`*.

Alternate Options

`watch cmd`	Linux and Mac OS X: `-v` Windows: None

-
- `v`

WB

Turns a compile-time bounds check into a warning.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-WB`

Windows:

`/WB`

Arguments

None

Default

OFF	Compile-time bounds checks are errors.

Description

This option turns a compile-time bounds check into a warning.

Alternate Options

None

what

Tells the compiler to display its detailed version string.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-what`

Windows:

`/what`

Arguments

None

Default

OFF	The version strings are not displayed.

Description

This option tells the compiler to display its detailed version string.

Alternate Options

None

winapp

Tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.

IDE Equivalent

Windows: **Libraries > Use Common Windows Libraries**

Linux: None

Mac OS X: None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`None`

Windows:

`/winapp`

Arguments

None

Default

OFF	No graphics or Fortran Windows application is created.

Description

This option tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.

Alternate Options

Linux and Mac OS X: None

Windows: `/MG`

Winline

Enables diagnostics about what is inlined and what is not inlined.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-Winline
```

Windows:

```
None
```

Arguments

None

Default

OFF	No diagnostics are produced about what is inlined and what is not inlined.

Description

This option enables diagnostics about what is inlined and what is not inlined. The diagnostics depend on what interprocedural functionality is available.

Alternate Options

None

Wl

Passes options to the linker for processing.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Wl,option1[,option2,...]`

Windows:

`None`

Arguments

option	Is a linker option. This option is not processed by the driver and is directly passed to the linker.

Default

OFF	No options are passed to the linker.

Description

This option passes one or more options to the linker for processing. If the linker is not invoked, these options are ignored.

This option is equivalent to specifying option `-Qoption,link,options`.

Alternate Options

None

See Also

-
- `Qoption`

Wp

Passes options to the preprocessor.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Wp,option1[,option2,...]`

Windows:

`None`

Arguments

option	Is a preprocessor option. This option is not processed by the driver and is directly passed to the preprocessor.

Default

OFF	No options are passed to the preprocessor.

Description

This option passes one or more options to the preprocessor. If the preprocessor is not invoked, these options are ignored.

This option is equivalent to specifying option `-Qoption, fpp, options`.

Alternate Options

None

-
- Qoption

x, Qx

Tells the compiler to generate optimized code specialized for the Intel processor that executes your program.

IDE Equivalent

Windows: **Code Generation > Intel Processor-Specific Optimization**

Optimization > Use Intel(R) Processor Extensions

Linux: None

Mac OS X: **Code Generation > Intel Processor-Specific Optimization**

Architectures

IA-32, Intel® 64 architectures

Syntax

Linux and Mac OS X:

-xprocessor

Windows:

/Qxprocessor

Arguments

processor	Indicates the processor for which code is generated. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (Intel® SSSE). Possible values are:

`Host`	Can generate instructions for the highest instruction set available on the compilation host processor. On Intel processors, this may correspond to the most suitable `-x` (Linux* and Mac OS* X) or `/Qx` (Windows*) option. On non-Intel processors, this may correspond to the most suitable `-m` (Linux and Mac OS X) or `/arch` (Windows) option. The resulting executable may not run on a processor different from the host in the following cases: • If the processor does not support all of the instructions supported by the host processor. • If the host is an Intel processor and the other processor is a non-Intel processor.
`AVX`	Optimizes for Intel processors that support Intel® Advanced Vector Extensions (Intel® AVX).
`SSE4.2`	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.
`SSE4.1`	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture. This replaces value S, which is deprecated.

SSE3_ATOM	Optimizes for the Intel® Atom™ processor and Intel® Centrino® Atom™ Processor Technology. Can generate MOVBE instructions, depending on the setting of option -minstruction (Linux and Mac OS) or /Qinstruction (Windows).
SSSE3	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. For Mac OS* X systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.
SSE3	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. For Mac OS* X systems, this value is only supported on IA-32 architecture.This replaces value P, which is deprecated.
SSE2	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2. This value is not available on Mac OS* X systems. This replaces value N, which is deprecated.

Default

Windows* systems: None Linux* systems: None Mac OS* X systems using IA-32 architecture: SSE3 Mac OS* X systems using Intel® 64 architecture: SSSE3	On Windows systems, if neither /Qx nor /arch is specified, the default is /arch:SSE2. On Linux systems, if neither -x nor -m is specified, the default is -msse2.

Description

This option tells the compiler to generate optimized code specialized for the Intel processor that executes your program. It also enables optimizations in addition to Intel processor-specific optimizations. The specialized code generated by this option may run only on a subset of Intel processors.

This option can enable optimizations depending on the argument specified. For example, it may enable Intel® Streaming SIMD Extensions 4 (Intel® SSE4), Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3), Intel® Streaming SIMD Extensions 3 (Intel® SSE3), Intel® Streaming SIMD Extensions 2 (Intel® SSE2), or Intel® Streaming SIMD Extensions (Intel® SSE) instructions.

The binaries produced by these values will run on Intel processors that support all of the features for the targeted processor. For example, binaries produced with SSE3 will run on an Intel® Core™ 2 Duo processor, because that processor completely supports all of the capabilities of the Intel® Pentium® 4 processor, which the SSE3 value targets. Specifying the SSSE3 value has the potential of using more features and optimizations available to the Intel® Core™ 2 Duo processor.

Do not use *processor* values to create binaries that will execute on a processor that is not compatible with the targeted processor. The resulting program may fail with an illegal instruction exception or display other unexpected behavior. For example, binaries produced with SSE3 may produce code that will not run on Intel® Pentium® III processors or earlier processors that do not support SSE3 instructions.

Compiling the main program with any of the *processor* values produces binaries that display a fatal run-time error if they are executed on unsupported processors. For more information, see *Optimizing Applications*.

If you specify more than one *processor* value, code is generated for only the highest-performing processor specified. The highest-performing to lowest-performing *processor* values are: SSE4.2, SSE4.1, SSSE3, SSE3, SSE2. Note that *processor* values AVX and SSE3_ATOM do not fit within this group.

Compiler options `m` and `arch` produce binaries that should run on processors not made by Intel that implement the same capabilities as the corresponding Intel processors.

Previous value O is deprecated and has been replaced by option `-msse3` (Linux and Mac OS X) and option `/arch:SSE3` (Windows).

Previous values W and K are deprecated. The details on replacements are as follows:

- Mac OS X systems: On these systems, there is no exact replacement for W or K. You can upgrade to the default option `-msse3` (IA-32 architecture) or option `-mssse3` (Intel® 64 architecture).

- Windows and Linux systems: The replacement for W is `-msse2` (Linux) or `/arch:SSE2` (Windows). There is no exact replacement for K. However, on Windows systems, `/QxK` is interpreted as `/arch:IA32`; on Linux systems, `-xK` is interpreted as `-mia32`. You can also do one of the following:
  - Upgrade to option `-msse2` (Linux) or option `/arch:SSE2` (Windows). This will produce one code path that is specialized for Intel® SSE2. It will not run on earlier processors
  - Specify the two option combination `-mia32 -axSSE2` (Linux) or `/arch:IA32 /QaxSSE2` (Windows). This combination will produce an executable that runs on any processor with IA-32 architecture but with an additional specialized Intel® SSE2 code path.

The `-x` and `/Qx` options enable additional optimizations not enabled with option `-m` or option `/arch`.

On Windows* systems, options `/Qx` and /arch are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning. Similarly, on Linux* and Mac OS* X systems, options `-x` and `-m` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

Alternate Options

None

X

Removes standard directories from the include file search path.

IDE Equivalent

Windows: **Preprocessor > Ignore Standard Include Path** (/noinclude)

Linux: None

Mac OS X: **Preprocessor > Ignore Standard Include Path** (/noinclude)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-X`

Windows:

`/X`

Arguments

None

Default

OFF	Standard directories are in the include file search path.

Description

This option removes standard directories from the include file search path. It prevents the compiler from searching the default path specified by the FPATH environment variable.

On Linux and Mac OS X systems, specifying `-X` (or `-noinclude`) prevents the compiler from searching in /usr/include for files specified in an INCLUDE statement.

You can use this option with the `I` option to prevent the compiler from searching the default path for include files and direct it to use an alternate path.

This option affects fpp preprocessor behavior and the USE statement.

Alternate Options

Linux and Mac OS X: `-nostdinc`

Windows: /noinclude

-
- `I`

Xlinker

Passes a linker option directly to the linker.

IDE Equivalent

None

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-Xlinker` *option*

Windows:

`None`

Arguments

option	Is a linker option.

Default

OFF	No options are passed directly to the linker.

Description

This option passes a linker option directly to the linker.
If `-Xlinker -shared` is specified, only `-shared` is passed to the linker and no special work is done to ensure proper linkage for generating a shared object. `-Xlinker` just takes whatever arguments are supplied and passes them directly to the linker.

If you want to pass compound options to the linker, for example "`-L $HOME/lib`", you must use the following method:

```
-Xlinker -L -Xlinker $HOME/lib
```

Alternate Options

None

-
- `shared`
- `link`

y

See syntax-only.

g, Zi, Z7

Tells the compiler to generate full debugging information in the object file.

IDE Equivalent

Windows: **General > Debug Information Format** (`/Z7, /Zd, /Zi`)

Linux: None

Mac OS X: **General > Generate Debug Information** (`-g`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-g`

Windows:

`/Zi`

`/Z7`

Arguments

None

Default

OFF	No debugging information is produced in the object file.

Description

This option tells the compiler to generate symbolic debugging information in the object file for use by debuggers.

The compiler does not support the generation of debugging information in assemblable files. If you specify this option, the resulting object file will contain debugging information, but the assemblable file will not.

This option turns off `O2` and makes `O0` (Linux and Mac OS X) or `Od` (Windows) the default unless `O2` (or another `O` option) is explicitly specified in the same command line.

On Linux systems using Intel® 64 architecture and Linux and Mac OS X systems using IA-32 architecture, specifying the `-g` or `-O0` option sets the `-fno-omit-frame-pointer` option.

For more information on `Zi` and `Z7`, see keyword `full` in debug (Windows*).

Alternate Options

Linux and Mac OS X: None

Windows: `/debug:full` (or `/debug`)

See Also

-
-
-
- `Zd`

Zd

This option has been deprecated. Use keyword `minimal` *in debug (Windows*).*

zero, Qzero

Initializes to zero all local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are saved but not yet initialized.

IDE Equivalent

Windows: **Data > Initialize Local Saved Scalars to Zero**

Linux: None

Mac OS X: **Data > Initialize Local Saved Scalars to Zero**

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

`-zero`

`-nozero`

Windows:

`/Qzero`

`/Qzero-`

Arguments

None

Default

`-nozero` or `/Qzero-`	Local scalar variables are not initialized to zero.

Description

This option initializes to zero all local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are saved but not yet initialized.

Use `-save` (Linux and Mac OS X) or `/Qsave` (Windows) on the command line to make all local variables specifically marked as SAVE.

Alternate Options

None

See Also

-
-
- `save`

g, Zi, Z7

Tells the compiler to generate full debugging information in the object file.

IDE Equivalent

Windows: **General > Debug Information Format** (`/Z7`, `/Zd`, `/Zi`)

Linux: None

Mac OS X: **General > Generate Debug Information** (`-g`)

Architectures

IA-32, Intel® 64, IA-64 architectures

Syntax

Linux and Mac OS X:

```
-g
```

Windows:

```
/Zi
/Z7
```

Arguments

None

Default

OFF	No debugging information is produced in the object file.

Description

This option tells the compiler to generate symbolic debugging information in the object file for use by debuggers.

The compiler does not support the generation of debugging information in assemblable files. If you specify this option, the resulting object file will contain debugging information, but the assemblable file will not.

This option turns off `O2` and makes `O0` (Linux and Mac OS X) or `Od` (Windows) the default unless `O2` (or another `O` option) is explicitly specified in the same command line.

On Linux systems using Intel® 64 architecture and Linux and Mac OS X systems using IA-32 architecture, specifying the `-g` or `-O0` option sets the `-fno-omit-frame-pointer` option.

For more information on `Zi` and `Z7`, see keyword `full` in debug (Windows*).

Alternate Options

Linux and Mac OS X: None

Windows: `/debug:full` (or `/debug`)

See Also

-
-
-
- `Zd`

ZI

See keyword `none` *in libdir*

Zp

See keyword `recnbyte` *in align.*

Zs

See syntax-only.

Zx

Disables certain optimizations that make it difficult to debug optimized code.

IDE Equivalent

None

Architectures

IA-64 architecture

Syntax

Linux and Mac OS X:

`None`

Windows:

`/Zx`

Arguments

None

Default

OFF	Optimizations are not disabled.

Description

Disables certain optimizations, such as software pipelining and global scheduling, that make it difficult to debug resultant code because of speculation.

Alternate Options

None

Quick Reference Guides and Cross References

The topic summarizes Intel® Fortran compiler options used on Windows* OS, Linux* OS and Mac OS* X.

If you want to see the summarized Windows* OS options, see this topic.

If you want to see the summarized Linux* OS and Mac OS* X options, see this topic.

Windows* OS Quick Reference Guide and Cross Reference

The table in this section summarizes Intel® Fortran compiler options used on Windows* OS . Each summary also shows the equivalent compiler options on Linux* OS and Mac OS* X.

If you want to see the summarized Linux* OS and Mac OS* X options, see this table.

Some compiler options are only available on systems using certain architectures, as indicated by these labels:

Label	Meaning
i32	The option is available on systems using IA-32 architecture.
i64em	The option is available on systems using Intel® 64 architecture.
i64	The option is available on systems using IA-64 architecture.

If "only" appears in the label, the option is only available on the identified system or architecture.

If no label appears, the option is available on all supported systems and architectures.

For more details on the options, refer to the Alphabetical Compiler Options section.

The Intel® Fortran Compiler includes the Intel® Compiler Option Mapping tool. This tool lets you find equivalent options by specifying compiler option `-map-opts` (Linux OS and Mac OS X) or `/Qmap-opts` (Windows OS).

For information on conventions used in this table, see Conventions.

Quick Reference of Windows* OS Options

The following table summarizes all supported Windows* OS options. It also shows equivalent Linux* OS and Mac OS* X options, if any.

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/1	Executes at least one iteration of DO loops.	OFF	-1
/4I{2|4|8}	Specifies the default KIND for integer and logical variables; same as the /integer-size option.	/4I4	-i{2|4|8}
/4L{72|80|132}	Treats the statement field of each fixed-form source line as ending in column 72, 80, or 132; same as the /extend-source option.	/4L72	-72, -80, -132
/4Na, /4Ya	Determines where local variables are stored. /4Na is the same as /save. /4Ya is the same as /automatic.	/4Ya	None
/4Naltparam, /4Yaltparam	Determines whether alternate syntax is allowed for PARAMETER statements; same as the /altparam option).	/4Yaltparam	None
/4Nb, /4Yb	Determines whether checking is performed for	/4Nb	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	run-time failures (same as the /check option).		
/4Nd, /4Yd	Determines whether error messages are issued for undeclared symbols. /4Nd is the same as /warn:nodeclarations. /4Yd is the same as /warn:declarations.	/4Nd	-warn nodeclarations, -warn declarations
/4Nf, /4Yf	Specifies the format for source files. /4Nf is the same as /fixed. /4Yf is the same as /free.	/4Nf	-fixed, -free
/4Nportlib, /4Yportlib	Determines whether the compiler links to the library of portability routines.	/4Yportlib	None
/4Ns, /4Ys	Determines whether the compiler changes warning messages about Fortran standards violations to error messages. /4Ns is the same as /stand:none. /4Ys is the same as /stand:f90.	/4Ns	-stand none, -stand f90

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/4R8, /4R16	Specifies the default KIND for real and complex variables. /4R8 is the same as /real-size:64. /4R16 is the same as /real-size:128.	OFF	-real-size 64, -real-size 128
/align[:*keyword*]	Tells the compiler how to align certain data items.	keywords: nocommons nodcommons records nosequence	-align [*keyword*]
/allow:*keyword*	Determines how the fpp preprocessor treats Fortran end-of-line comments in preprocessor directive lines.	keyword: fpp_comments	/allow *keyword*
/[no]altparam	Allows alternate syntax (without parentheses) for PARAMETER statements.	/altparam	-[no]altparam
/arch:*processor* (i32, i64em)	Tells the compiler to generate optimized code specialized for the processor that executes your program; same as option /architecture.	varies; see option description	-arch *processor* or -m *processor* (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/asmattr:*keyword*	Specifies the contents of an assembly listing file.	/noasmattr	None
/asmfile[:*file* | *dir*]	Specifies that an assembly listing file should be generated.	/noasmfile	None
/assume:*keyword*	Tells the compiler to make certain assumptions.	keywords: [no]bscc [no]buffered_io [no]byterecl [no]cc_omp [no]dummy_aliases [no]ieee_fpe_flags [no]minus0 [no]old_boz [no]old_logical_ldio [no]old_maxminloc [no]old_unit_star [no]old_xor [no]protect_constants [no]protect_parens [no]realloc_lhs [no]source_include [no]std_mod_proc_name [no]underscore [no]writeable-strings	-assume *keyword*
/[no]automatic	Causes all variables to be allocated to the run-time stack; same as the /auto option.	/Qauto-scalar	-[no]automatic

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/bigobj	Increases the number of sections that an object file can contain.	OFF	None
/bintext:*string*	Places a text string into the object file (.obj) being generated by the compiler.	OFF	None
/c	Prevents linking.	OFF	-c
/C	Performs checking for all run-time failures; same as the /check:all option.	OFF	-C
/CB	Performs run-time checking on array subscript and character substring expressions; same as the /check:bounds option.	OFF	-CB
/ccdefault:*keyword*	Specifies the type of carriage control used when a file is displayed at a terminal screen.	/ccdefault:default	-ccdefault *keyword*
/check[:*keyword*]	Checks for certain conditions at run time.	/nocheck	-check [*keyword*]

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/cm	Disables all messages about questionable programming practices; same as specifying option /warn:nousage.	OFF	-cm
/compile-only	Causes the compiler to compile to an object file only and not link; same as the /c option.	OFF	None
/Qcomplex-limited-range[-]	Enables the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX.	/Qcomplex-limited-range-	-[no-]complex-limited-range
/convert:*keyword*	Specifies the format of unformatted files containing numeric data.	/convert:native	-convert *keyword*
/CU	Enables run-time checking for uninitialized variables. This option is the same as /check:uninit and /RTCu.	OFF	-CU

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/D*name* [=*value*]	Defines a symbol name that can be associated with an optional value.	/noD	-D*name* [=*value*]
/[no]d-lines	Compiles debugging statements indicated by the letter D in column 1 of the source code.	/nod-lines	-[no]d-lines
/[no]dbglibs	Tells the linker to search for unresolved references in a debug run-time library.	/nodbglibs	None
/debug:*keyword*	Specifies the type of debugging information generated by the compiler in the object file.	/debug:full (IDE) /debug:none (command line)	-debug *keyword* Note: the Linux* OS and Mac OS* X option takes different *keyword* s
/debug-parameters[:*keyword*]	Tells the compiler to generate debug information for PARAMETERs used in a program.	/nodebug-parameters	-debug-parameters [*keyword*]
/define:*name* [=*value*]	Defines a symbol name that can be associated with an optional value; same as the /D<name>[=value] option.	OFF	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/dll	Specifies that a program should be linked as a dynamic-link (DLL) library.	OFF	None
/double-size:*size*	Defines the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX variables.	/double-size:64	-double-size *size*
/E	Causes the Fortran preprocessor to send output to stdout.	OFF	-E
/EP	Causes the Fortran preprocessor to send output to stdout, omitting #line directives.	OFF	-EP
/error-limit:*n*	Specifies the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line.	/error-limit:30	-error-limit *n*
/exe:{*file* | *dir*}	Specifies the name for a built program or dynamic-link library.	OFF	-o

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/extend-source[:*size*]	Specifies the length of the statement field in a fixed-form source file.	/extend-source:72	-extend-source [*size*]
/extfor:ext	Specifies file extensions to be processed by the compiler as Fortran files.	OFF	None
/extfpp:ext	Specifies file extensions to be recognized as a file to be preprocessed by the Fortran preprocessor.	OFF	None
/extlnk:ext	Specifies file extensions to be passed directly to the linker.	OFF	None
/F*n*	Specifies the stack reserve amount for the program.	OFF	None
/f66	Tells the compiler to apply FORTRAN 66 semantics.	OFF	-f66
/f77rtl	Tells the compiler to use the run-time behavior of FORTRAN 77.	OFF	-f77rtl

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Fa[:*file* | *dir*]	Specifies that an assembly listing file should be generated; same as option /asmfile and /S.	OFF	-S
/FAc, /FAs, /FAcs	Specifies the contents of an assembly listing file. /FAc is the same as the /asmattr:machine option. /FAs is the same as the /asmattr:source option. /FAcs is the same as the /asmattr:all option.	OFF	None
/fast	Maximizes speed across the entire program.	OFF	-fast
/Fe*file*	Specifies the name for a built program or dynamic-link library; same as the /exe option.	OFF	-o
/FI	Specifies source files are in fixed format; same as the /fixed option.	determined by file suffix	-FI
/[no]fixed	Specifies source files are in fixed format.	determined by file suffix	-[no]fixed

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/[no]fltconsisten-cy	Enables improved floating-point consistency.	/nofltconsistency	-[no]fltconsisten-cy
/Fm[*file*]	Tells the linker to generate a link map file; same as the /map option.	OFF	None
/Fo*file*	Specifies the name for an object file; same as the /object option.	OFF	None
/fp:*keyword*	Controls the semantics of floating-point calculations.	/fp:fast=1	-fp-model *keyword*
/[no]fpconstant	Tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.	/nofpconstant	-[no]fpconstant
/fpe:*n*	Specifies the floating-point exception handling level for the main program at run-time.	/fpe:3	-fpe*n*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/fpe-all:*n*	Specifies the floating-point exception handling level for each routine at run-time.	/fpe-all:3	-fpe-all=*n*
/fpp [*n*] /fpp[="*option*"]	Runs the Fortran preprocessor on source files before compilation.	/nofpp	- fpp[*n*] - fpp[="*option*"]
/fpscomp[:*keyword*]	Specifies compatibility with Microsoft* Fortran PowerStation or Intel® Fortran.	/fpscomp:libs	-fpscomp [*keyword*]
/FR	Specifies source files are in free format; same as the /free option.	determined by file suffix	-FR
/[no]free	Specifies source files are in free format.	determined by file suffix	-[no]free
/G2 (i64 only)	Optimizes application performance for systems using IA-64 architecture.	OFF	None
/G2-p9000 (i64 only)	Optimizes for Dual-Core Intel® Itanium® 2 Processor 9000 series.	ON	-mtune itanium2-p9000

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/G{5|6|7} (i32, i64em)	Optimizes application performance for systems using IA-32 architecture and Intel® 64 architecture. These options have been deprecated.	/G7	None
/GB	Optimizes for Intel® Pentium® Pro, Pentium® II and Pentium® III processors; same as the /G6 option.	OFF	None
/Ge	Enables stack-checking for all functions. Deprecated.	OFF	None
/gen-interfaces[:[no]source]	Tells the compiler to generate an interface block for each routine in a source file.	/nogen-interfaces	-gen-interfaces [[no]source]
/Gm	Tells the compiler to use calling convention CVF; same as the /iface:cvf option.	OFF	None
/Gs[n]	Disables stack-checking for routines with a specified number of	/Gs4096	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	bytes of local variables and compiler temporaries.		
/GS[-]	Determines whether the compiler generates code that detects some buffer overruns.	/GS-	-f[no-]stack-security-check
/Gz	Tells the compiler to use calling convention STDCALL; same as the /iface:stdcall option.	OFF	None
/heap-arrays[:*size*]	Puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.	/heap-arrays-	-heap-arrays [*size*]
/help[*category*]	Displays all available compiler options or a category of compiler options; same as the /? option.	OFF	-help
/homeparams	Tells the compiler to store parameters passed in registers to the stack.	OFF	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/hotpatch (i32, i64em)	Tells the compiler to prepare a routine for hotpatching.	OFF	None
/I:*dir*	Specifies a directory to add to the include path.	OFF	-I*dir*
/iface:*keyword*	Specifies the default calling convention and argument-passing convention for an application.	/iface:default	None
/include	Specifies a directory to add to the include path; same as the /I option.	OFF	None
/inline[:*keyword*]	Specifies the level of inline function expansion.	OFF	None
/[no]intconstant	Tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.	/nointconstant	-[no]intconstant
/integer-size:*size*	Specifies the default KIND for integer and logical variables.	/integer-size:32	-integer-size *size*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
`/LD`	Specifies that a program should be linked as a dynamic-link (DLL) library.	OFF	None
`/libdir`[`:`*`keyword`*]	Controls whether linker options for search libraries are included in object files generated by the compiler.	`/libdir:all`	None
`/libs:`*`keyword`*	Tells the linker to search for unresolved references in a specific run-time library.	`/libs:static`	None
`/link`	Passes options to the linker at compile time.	OFF	None
`/[no]logo`	Displays the compiler version information.	`/logo`	`-[no]logo`
`/map[:`*`file`*`]`	Tells the linker to generate a link map file.	`/nomap`	None
`/MD` and `/MDd`	Tells the linker to search for unresolved references in a multithreaded, debug, dynamic-link run-time library.	OFF	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/MDs and /MDsd	Tells the linker to search for unresolved references in a single-threaded, dynamic-link run-time library.	OFF	None
/MG	Tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.	OFF	None
/ML and /MLd	Tells the linker to search for unresolved references in a single-threaded, static run-time library.	i32, i64: /ML i64em: OFF	None
/module:*path*	Specifies the directory where module files should be placed when created and where they should be searched for.	OFF	-module *path*
/MP[:*n*]	Creates multiple processes that can be used to compile large numbers of source files at the same time.	OFF	-multiple-process-es[:*n*]

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/MT and /MTd	Tells the linker to search for unresolved references in a multithreaded, static run-time library.	i32, i64: OFF i64em: /MT/noreen-trancy	None
/MW	Tells the linker to search for unresolved references in a Fortran QuickWin library; same as /libs:qwin.	OFF	None
/MWs	Tells the linker to search for unresolved references in a Fortran standard graphics library; same as /libs:qwins.	OFF	None
/names:*keyword*	Specifies how source code identifiers and external names are interpreted.	/names:uppercase	-names *keyword*
/nbs	Tells the compiler to treat the backslash character (\) as a normal character in character literals; same as the /assume:nobscc option.	/nbs	-nbs

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/noinclude	Removes standard directories from the include file search path; same as the /X option.	OFF	None
/O[*n*]	Specifies the code optimization for applications.	/O2	-O[*n*]
/Ob*n*	Specifies the level of inline function expansion. *n* = 0, 1, or 2.	/Ob2 if /O2 is in effect or /O3 is specified /Ob0 if /Od is specified	-inline-level=*n*
/object:*file*	Specifies the name for an object file.	OFF	None
/Od	Disables optimizations.	OFF	-O0
/Og	Enables global optimizations.	/Og	None
/Op	Enables improved floating-point consistency.	OFF	-mp
/optimize:*n*	Affects optimizations performed by the compiler; *n* = 1, 2, 3, or 4.	/optimize:3 or /optimize:4	-O*n*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Os	Enables optimizations that do not increase code size and produces smaller code size than O2.	OFF (unless /O1 is specified)	-Os
/Ot	Enables all speed optimizations.	/Ot (unless /O1 is specified)	None
/Ox	Same as the /O2 option.	/Ox	-O2
/Oy[-] (i32 only)	Determines whether EBP is used as a general-purpose register in optimizations.	/Oy (unless /Od is specified)	-f[no-]omit-frame-pointer (i32, i64em)
/P	Causes the Fortran preprocessor to send output to a file, which is named by default; same as the -preprocess-only option.	OFF	-P
/[no]pad-source	Specifies padding for fixed-form source records.	/nopad-source	-[no]pad-source
/pdbfile[:*file*]	Specifies that any debug information generated by the compiler should be saved to a program database file.	/nopdbfile	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/preprocess-only	Causes the Fortran preprocessor to send output to a file.	/nopreprocess-only	-preprocess-only
/Qansi-alias	Tells the compiler to assume the program adheres to the Fortran Standard type aliasability rules.	/Qansi-alias	-ansi-alias
/Qauto	Causes all variables to be allocated on the stack, rather than in local static storage.	/Qauto-scalar	-auto
/Qauto-scalar	Causes allocation of scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL to the run-time stack.	/Qauto-scalar	-auto-scalar
/Qautodouble	Makes default real and complex variables 8 bytes long; same as the /real-size:64 option.	OFF	-autodouble
/Qax*p* (i32, i64em)	Tells the compiler to generate multiple, processor-specific auto-dispatch code paths for Intel	OFF	-ax*p* (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	processors if there is a performance benefit.		
/Qchkstk[-] (i64 only)	Enables stack probing when the stack is dynamically expanded at run-time.	/Qchkstk	None
/Qcommon-args	Tells the compiler that dummy (formal) arguments to procedures share memory locations with other dummy arguments or with COMMON variables that are assigned; same as /assume:dummy_aliases.	OFF	-common-args
/Qcomplex-limited-range[-]	Enables the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX.	/Qcomplex-limited-range-	-[no-]complex-limited-range
/Qcpp	Runs the Fortran preprocessor on source files before compilation; same as the /fpp option.	OFF	-cpp

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qd-lines[-]	Compiles debugging statements indicated by the letter D in column 1 of the source code; can also be specified as /d-lines.	OFF	-[no]d-lines
/Qdiag-*type*: *diag-list*	Controls the display of diagnostic information.	OFF	-diag-*type* *diag-list*
/Qdiag-dump	Tells the compiler to print all enabled diagnostic messages and stop compilation.	OFF	-diag-dump
/Qdiag-enable:sc-include (i32, i64em)	Tells the Source Checker to analyze include files and source files when issuing diagnostic message. This is equivalent to deprecated option /Qdiag-enable:sv-include.	OFF	-diag-enable sc-include (i32, i64em)
/Qdiag-enable:sc-parallel (i32, i64em)	Enables analysis of parallelization in source code (parallel lint diagnostics).	OFF	-diag-enable sc-parallel (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qdiag-error-limit:*n*	Specifies the maximum number of errors allowed before compilation stops.	/Qdiag-error-limit:30	-diag-error-limit*n*
/Qdiag-file[:*file*]	Causes the results of diagnostic analysis to be output to a file.	OFF	-diag-file[= *file*]
/Qdiag-file-append[:*file*]	Causes the results of diagnostic analysis to be appended to a file.	OFF	-diag-file-append[= *file*]
/Qdiag-id-numbers[-]	Tells the compiler to display diagnostic messages by using their ID number values.	/Qdiag-id-numbers	-[no-]diag-id-numbers
/Qdiag-once:*id*[,*id*,...]	Tells the compiler to issue one or more diagnostic messages only once	OFF	-diag-once *id*[,*id*,...]
/Qdps	Specifies that the alternate syntax for PARAMETER statements is allowed; same as the /altparam option.	/Qdps	-dps
/Qdyncom "common1,common2,..."	Enables dynamic allocation of common blocks at run time.	OFF	-dyncom "common1,common2,..."

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qextend-source	This is the same as specifying option /extend-source:132.	OFF	-extend-source *size*
/Qfast-transcendentals[-]	Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.	/Qfast-transcendentals	-[no-]fast-transcendentals
/Qfma[-] (i64 only)	Enables the combining of floating-point multiplies and add/subtract operations.	/Qfma	-[no-]fma (i64 only; Linux* OS only)
/Qfnalign[:*n*] (i32, i64em)	Tells the compiler to align functions on an optimal byte boundary.	/Qfnalign-	-falign-functions[=*n*] (i32, i64em)
/Qfnsplit[-] (i32, i64)	Enables function splitting.	/Qfnsplit-	-[no-]fnsplit (i64 only; Linux* OS only)
/Qfp-port[-] (i32, i64em)	Rounds floating-point results after floating-point operations.	/Qfp-port-	-[no-]fp-port (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
`/Qfp-relaxed[-]` (i64 only)	Enables use of faster but slightly less accurate code sequences for math functions, such as divide and sqrt.	`/Qfp-relaxed-`	`-[no-]fp-relaxed` (i64 only; Linux* OS only)
`/Qfp-specula-tion:`*mode*	Tells the compiler the mode in which to speculate on floating-point operations.	`/Qfp-specula-tion:fast`	`-fp-specula-tion=`*mode*
`/Qfp-stack-check` (i32, i64em)	Generates extra code after every function call to ensure that the FP (floating-point) stack is in the expected state.	OFF	`-fp-stack-check` (i32, i64em)
`/Qfpp[`*n*`]`	Runs the Fortran preprocessor on source files before compilation.	`/nofpp`	`-fpp[`*n*`]`
`/Qftz[-]`	Flushes denormal results to zero.	i64: `/Qftz-` i32, i64em: `/Qftz`	`-[no-]ftz`
`/Qglobal-hoist[-]`	Enables certain optimizations that can move memory loads to a point earlier in the	`/Qglobal-hoist-`	`-[no-]global-hoist`

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	program execution than where they appear in the source.		
/QIA64-fr32 (i64 only)	Disables use of high floating-point registers.	OFF	None
/QIfist (i32 only)	Enables fast float-to-integer conversions; same as option /Qrcd.	OFF	None
/Qimsl	Tells the compiler to link to the IMSL* Fortran Numerical Library* (IMSL* library).	OFF	None
/Qinline-debug-info	Produces enhanced source position information for inlined code.	OFF	-inline-debug-info
/Qinline-dl-limport[-]	Determines whether dllimport functions are inlined.	/Qinline-dl-limport	None
/Qinline-factor==*n*	Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.	/Qinline-factor-	-inline-factor=*n*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
`/Qinline-forcein-line`	Specifies that an inline routine should be inlined whenever the compiler can do so.	OFF	`-inline-forcein-line`
`/Qinline-max-per-compile=`*n*	Specifies the maximum number of times inlining may be applied to an entire compilation unit.	`/Qinline-max-per-compile-`	`-inline-max-per-compile=`*n*
`/Qinline-max-per-routine=`*n*	Specifies the maximum number of times the inliner may inline into a particular routine.	`/Qinline-max-per-routine-`	`-inline-max-per-routine=`*n*
`/Qinline-max-size=`*n*	Specifies the lower limit for the size of what the inliner considers to be a large routine.	`/Qinline-max-size-`	`-inline-max-size=`*n*
`/Qinline-max-to-tal-size=`*n*	Specifies how much larger a routine can normally grow when inline expansion is performed.	`/Qinline-max-to-tal-size-`	`-inline-max-to-tal-size=`*n*
`/Qinline-min-size=`*n*	Specifies the upper limit for the size of what the inliner considers to be a small routine.	`/Qinline-min-size-`	`-inline-min-size=`*n*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qinstruction:[no]movbe (i32, i64em)	Determines whether MOVBE instructions are generated for Intel processors.	OFF	-minstruction=[no]movbe (i32, i64em)
/Qinstrument-functions[-]	Determines whether function entry and exit points are instrumented.	/Qinstrument-functions-	-f[no-]instrument-functions
/Qip[-]	Enables additional single-file interprocedural optimizations.	OFF	-[no-]ip
/Qip-no-inlining	Disables full and partial inlining enabled by -ip.	OFF	-ip-no-inlining
/Qip-no-pinlining (i32, i64em)	Disables partial inlining.	OFF	-ip-no-pinlining (i32, i64em)
/QIPF-flt-eval-method0 (i64 only)	Tells the compiler to evaluate the expressions involving floating-point operands in the precision indicated by the variable types declared in the program. Deprecated.	OFF	-[no-]IPF-flt-eval-method0 (i64 only; Linux* OS only)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/QIPF-fltacc[-] (i64 only)	Tells the compiler to apply optimizations that affect floating-point accuracy. Deprecated.	/QIPF-fltacc-	-IPF-fltacc (i64 only; Linux* OS only)
/QIPF-fma (i64 only)	Enables the combining of floating-point multiplies and add/subtract operations. Deprecated; use /Qfma.	/QIPF-fma	-IPF-fma (i64 only; Linux* OS only)
/QIPF-fp-relaxed (i64 only)	Enables use of faster but slightly less accurate code sequences for math functions, such as divide and sqrt. Deprecated; use /Qfp-relaxed.	/QIPF-fp-relaxed-	-IPF-fp-relaxed (i64 only; Linux* OS only)
/Qipo[n]	Enables multifile IP optimizations between files.	OFF	-ipo[n]
/Qipo-c	Generates a multifile object file that can be used in further link steps.	OFF	-ipo-c

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qipo-jobs: *n*	Specifies the number of commands to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).	/Qipo-jobs:1	-ipo-jobs*n*
/Qipo-S	Generates a multifile assembly file that can be used in further link steps.	OFF	-ipo-S
/Qipo-separate	Generates one object file per source file.	OFF	-ipo-separate (Linux* OS only)
/Qivdep-parallel (i64 only)	Tells the compiler that there is no loop-carried memory dependency in any loop following an IVDEP directive.	OFF	-ivdep-parallel (i64 only; Linux* OS only)
/Qkeep-static-consts[-]	Tells the compiler to preserve allocation of variables that are not referenced in the source.	/Qkeep-static-consts-	-f[no-]keep-static-consts
/Qlocation,*string*,*dir*	Specifies a directory as the location of the specified tool in *string* .	OFF	-Qlocation,*string*,*dir*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qlowercase	Causes the compiler to ignore case differences in identifiers and to convert external names to lowercase; same as the /names:lowercase option.	OFF	-lowercase
/Qmap-opts	Maps one or more Windows* compiler options to their equivalent on a Linux* OS system (or vice versa).	OFF	-map-opts
/Qmkl[=*lib*	Tells the compiler to link to certain parts of the Intel® Math Kernel Library.	OFF	-mkl[=*lib*
/Qnobss-init	Places any variables that are explicitly initialized with zeros in the DATA section.	OFF	-no-bss-init
/Qonetrip	This is the same as specifying option /onetrip.	OFF	-onetrip
/Qopenmp	Enables the parallelizer to generate	OFF	-openmp

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	multithreaded code based on OpenMP* directives.		
/Qopenmp-lib:*type*	Lets you specify an OpenMP* run-time library to use for linking.	/Qopenmp-lib:legacy	-openmp-lib *type* (Linux* OS only)
/Qopenmp-link:*library*	Lets you specify an OpenMP* run-time library to use for linking.	/Qopenmp-lib:legacy	-openmp-link *library* (Linux* OS only)
/Qopenmp-profile	Enables analysis of OpenMP* applications.	OFF	-openmp-profile (Linux* OS only)
/Qopenmp-report[*n*]	Controls the OpenMP parallelizer's level of diagnostic messages.	/Qopenmp-report1	-openmp-report[*n*]
/Qopenmp-stubs	Enables compilation of OpenMP programs in sequential mode.	OFF	-openmp-stubs
/Qopenmp-threadprivate:*type*	Lets you specify an OpenMP* threadprivate implementation.	/Qopenmp-threadprivate:legacy	-openmp-threadprivate *type* (Linux* OS only)
/Qopt-block-factor:*n*	Lets you specify a loop blocking factor.	OFF	-opt-block-factor=*n*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
`/Qopt-jump-tables:`*keyword*	Enables or disables generation of jump tables for switch statements.	`/Qopt-jump-tables:default`	`-opt-jump-tables=`*keyword*
`/Qopt-loadpair[-]` (i64 only)	Enables or disables loadpair optimization.	`/Qopt-loadpair-`	`-[no-]opt-load-pair` (i64 only; Linux* OS only)
`/Qopt-mem-band-width`*n* (i64 only)	Enables performance tuning and heuristics that control memory bandwidth use among processors.	`/Qopt-mem-band-width0` for serial compilation; `/Qopt-mem-bandwidth1` for parallel compilation	`-opt-mem-band-width`*n* (i64 only; Linux* OS only)
`/Qopt-mod-version-ing[-]` (i64 only)	Enables or disables versioning of modulo operations for certain types of operands.	`/Qopt-mod-version-ing-`	`-[no-]opt-mod-versioning` (i64 only; Linux* OS only)
`/Qopt-multi-ver-sion-aggres-sive[-]` (i32, i64em)	Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.	`/Qopt-multi-ver-sion-aggressive-`	`-[no-]opt-multi-version-aggres-sive` (i32, i64em)
`/Qopt-prefetch`[:*n*]	Enables prefetch insertion optimization.	i64: `/Qopt-prefetch` i32, i64em: `/Qopt-prefetch-`	`-opt-prefetch`[=*n*]

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qopt-prefetch-initial-values[-] (i64 only)	Enables or disables prefetches that are issued before a loop is entered.	/Qopt-prefetch-initial-values	-[no-]opt-prefetch-initial-values (i64 only; Linux* OS only)
/Qopt-prefetch-issue-excl-hint[-] (i64 only)	Determines whether the compiler issues prefetches for stores with exclusive hint.	/Qopt-prefetch-issue-excl-hint-	-[no-]opt-prefetch-issue-excl-hint (i64 only; Linux* OS only)
/Qopt-prefetch-next-iteration[-][:*n*] (i64 only)	Enables or disables prefetches for a memory access in the next iteration of a loop.	-opt-prefetch-next-iteration	/Qopt-prefetch-next-iteration (i64 only; Linux* OS only)
/Qopt-ra-region-strategy[:*keyword*] (i32, i64em)	Selects the method that the register allocator uses to partition each routine into regions.	/Qopt-ra-region-strategy:default	-opt-ra-region-strategy[=*keyword*] (i32, i64em)
/Qopt-report:*n*	Tells the compiler to generate an optimization report to *stderr*.	/Qopt-report:2	-opt-report *n*
/Qopt-report-file:*file*	Tells the compiler to generate an optimization report named *file*.	OFF	-opt-report-file=*file*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qopt-report-help	Displays the optimizer phases available for report generation.	OFF	-opt-report-help
/Qopt-report-phase:*phase*	Specifies an optimizer phase to use when optimization reports are generated.	OFF	-opt-report-phase=*phase*
/Qopt-report-routine:*string*	Generates a report on all routines or the routines containing the specified *string*.	OFF	-opt-report-routine=*string*
/Qopt-streaming-stores:*keyword* (i32, i64em)	Enables generation of streaming stores for optimization.	/Qopt-streaming-stores:auto	-opt-streaming-stores *keyword* (i32, i64em)
/Qopt-subscript-in-range[-] (i32, i64em)	Determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.	/Qopt-subscript-in-range-	-[no-]opt-subscript-in-range (i32, i64em)
/Qoption,*string*,*options*	Passes *options* to the tool specified in *string*.	OFF	-Qoption,*string*,*options*
/Qpad	Enables the changing of the variable and array memory layout.	/Qpad-	-pad

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qpad-source	This is the same as specifying option /pad-source.	/Qpad-source-	-pad-source
/Qpar-adjust-stack:*n* (i32, i64em)	Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.	/Qpar-adjust-stack:0	None
/Qpar-affinity:[*modifier*,...] *type*[,*permute*] [,*offset*]	Specifies thread affinity.	OFF	-par-affinity=[*modifier*,...]*type*[,*permute*][,*offset*] (Linux* OS only)
/Qpar-num-threads:*n*	Specifies the number of threads to use in a parallel region.	OFF	-par-num-threads=*n*
/Qpar-report[*n*]	Controls the diagnostic information reported by the auto-parallelizer.	/Qpar-report1	-par-report[*n*]
/Qpar-runtime-control[-]	Generates code to perform run-time checks for loops that have symbolic loop bounds.	/Qpar-runtime-control-	-[no-]par-run-time-control
/Qpar-schedule-*keyword* [[:] *n*]	Specifies a scheduling algorithm for DO loop iterations.	OFF	-par-schedule-*keyword*[=*n*]

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qpar-thresh-old[[:]*n*]	Sets a threshold for the auto-parallelization of loops.	/Qpar-thresh-old:100	-par-threshold[*n*]
/Qparallel	Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.	OFF	-parallel
/Qpc*n* (i32, i64em)	Enables control of floating-point significand precision.	/Qpc64	-pc*n* (i32, i64em)
/Qprec	Improves floating-point precision and consistency.	OFF	-mp1
/Qprec-div[-]	Improves precision of floating-point divides.	/Qprec-div-	-[no-]prec-div
/Qprec-sqrt (i32, i64em)	Improves precision of square root implementations.	/Qprec-sqrt-	-prec-sqrt (i32, i64em)
/Qprefetch	Enables prefetch insertion optimization. Deprecated; use /Qopt-prefetch	i64: /Qprefetch i32, i64em: /Qprefetch-	-prefetch

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qprof-data-order[-]	Enables or disables data ordering if profiling information is enabled.	/Qprof-data-order-	-[no-]prof-data-order (Linux* OS only)
/Qprof-dir *dir*	Specifies a directory for profiling information output files.	OFF	-prof-dir *dir*
/Qprof-file *file*	Specifies a file name for the profiling summary file.	OFF	-prof-file *file*
/Qprof-func-order[-]	Enables or disables function ordering if profiling information is enabled.	/Qprof-func-order-	-[no-]prof-func-order (Linux* OS only)
/Qprof-gen[:*keyword*]	Produces an instrumented object file that can be used in profile-guided optimization.	/Qprof-gen-	-prof-gen[=*keyword*]
/Qprof-genx	Produces an instrumented object file that includes extra source position information. Deprecated; use /Qprof-gen:srcpos.	OFF	-prof-genx

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qprof-hotness-threshold:*n*	Lets you set the hotness threshold for function grouping and function ordering.	OFF	-prof-hotness-threshold=*n* (Linux* OS only)
/Qprof-src-dir[-]	Determines whether directory information of the source file under compilation is considered when looking up profile data records.	/Qprof-src-dir	-[no-]prof-src-dir
/Qprof-src-root:*dir*	Lets you use relative directory paths when looking up profile data and specifies a directory as the base.	OFF	-prof-src-root=*dir*
/Qprof-src-root-cwd	Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.	OFF	-prof-src-root-cwd
/Qprof-use[:*arg*]	Enables the use of profiling information during optimization.	OFF	-prof-use[=*arg*]
/Qrcd (i32, i64em)	Enables fast float-to-integer conversions.	OFF	-rcd (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qrct (i32, i64em)	Sets the internal FPU rounding control to Truncate.	OFF	-rct (i32, i64em)
/Qsafe-cray-ptr	Tells the compiler that Cray* pointers do not alias other variables.	OFF	-safe-cray-ptr
/Qsave	Causes variables to be placed in static memory.	/Qauto-scalar	-save
/Qsave-temps[-]	Tells the compiler to save intermediate files created during compilation.	.obj files are saved	-[no-]save-temps
/Qscalar-rep[-] (i32 only)	Enables scalar replacement performed during loop transformation (requires /O3).	/Qscalar-rep-	-[no-]scalar-rep (i32 only)
/Qsfalign[n] (i32 only)	Specifies stack alignment for functions. *n* is 8 or 16.	/Qsfalign8	None
/Qsox[-]	Tells the compiler to save the compilation options and version number in the Windows* OS object file.	/Qsox-	-[no-]sox (Linux OS only)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
`/Qtcheck`	Enables analysis of threaded applications.	OFF	`-tcheck` (Linux* OS only)
`/Qtcollect`[: *lib*]	Inserts instrumentation probes calling the Intel(R) Trace Collector API.	OFF	`-tcollect`[= *lib*] (Linux* OS only)
`/Qtcollect-filter`[=*file*]	Lets you enable or disable the instrumentation of specified functions.	OFF	`-tcollect-filter` [*file*] (Linux* OS only)
`/Qtprofile`	Generates instrumentation to analyze multi-threading performance.	OFF	`-tprofile` (Linux* OS only)
`/Qtrapuv`	Initializes stack local variables to an unusual value.	OFF	`-ftrapuv`
`/Qunroll`[:*n*]	Tells the compiler the maximum number of times to unroll loops; same as the `/unroll[:n]` option.	`/Qunroll`	`-unroll`[=*n*]
`/Qunroll-aggressive[-]` (i32, i64em)	Determines whether the compiler uses more aggressive unrolling for certain loops.	`/Qunroll-aggressive-`	`-[no-]unroll-aggressive` (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Quppercase	Causes the compiler to ignore case differences in identifiers and to convert external names to uppercase; same as the /names:uppercase option.	/Quppercase	-uppercase
/Quse-asm[-] (i64 only)	Tells the compiler to produce objects through the assembler.	/Quse-asm-	-[no-]use-asm
/Quse-msasm-symbols (i32,i64em)	Tells the compiler to use a dollar sign ("$") when producing symbol names.	OFF	None
/Quse-vcdebug (i32 only)	Tells the compiler to issue debug information compatible with the Visual C++ debugger.	OFF	None
/Qvc7.1 /Qvc8 /Qvc9 (i32, i64em)	Specifies compatibility with Microsoft* Visual C++ or Microsoft* Visual Studio.	varies; see option description	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qvec[-] (i32, i64em)	Enables or disables vectorization and transformations enabled for vectorization.	/Qvec	-[no-]vec (i32, i64em)
/Qvec-guard-write[-] (i32, i64em)	Tells the compiler to perform a conditional check in a vectorized loop.	/Qvec-guard-write-	-[no-]vec-guard-write (i32, i64em)
/Qvec-report[*n*] (i32, i64em)	Controls the diagnostic information reported by the vectorizer.	/Qvec-report1	-vec-report[*n*] (i32, i64em)
/Qvec-thresh-old[[:]*n*] (i32, i64em)	Sets a threshold for the vectorization of loops.	/Qvec-thresh-old100	-vec-threshold[*n*] (i32, i64em)
/Qvms	Causes the run-time system to behave like HP Fortran for OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*) in certain ways; same as the /vms option.	/novms	-vms
/Qx*processor* (i32, i64em)	Tells the compiler to generate optimized code specialized for the Intel processor that executes your program.	varies; see the option description	-x*processor* (i32, i64em)

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/Qzero[-]	Initializes to zero all local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are saved but not yet initialized.	OFF	-[no]zero
/real-size:*size*	Specifies the default KIND for real variables.	/real-size:32	-real-size *size*
/[no]recursive	Tells the compiler that all routines should be compiled for possible recursive execution.	/norecursive	-[no]recursive
/reentrancy:*keyword*	Tells the compiler to generate reentrant code to support a multithreaded application.	/noreentrancy	-reentrancy *keyword*
/RTCu	Enables run-time checking for uninitialized variables; same as option /check:uninit.	OFF	-check uninit or -CU
/S	Causes the compiler to compile to an assembly file only and not link.	OFF	-S

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/source:*file*	Tells the compiler to compile the file as a Fortran source file.	OFF	None
/stand:*keyword*	Tells the compiler to issue compile-time messages for nonstandard language elements.	/nostand	-stand *keyword*
/static	Prevents linking with shared libraries.	/static	-static (Linux* OS only)
/syntax-only	Tells the compiler to check only for correct syntax.	OFF	-syntax-only
/Tf *file*	Tells the compiler to compile the file as a Fortran source file; same as the /source option.	OFF	-Tf *file*
/[no]threads	Tells the linker to search for unresolved references in a multithreaded run-time library.	i32, i64: /nothreads i64em: /threads	-[no]threads
/[no]traceback	Tells the compiler to generate extra information in the object file to provide source file traceback	/notraceback	-[no]traceback

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	information when a severe error occurs at run time.		
/tune:*keyword* (i32, i64em)	Determines the version of the architecture for which the compiler generates instructions.	/tune:pn4	-tune *keyword* (i32, i64em)
/u	Undefines all previously defined preprocessor values.	OFF	None Note: the Linux* OS and Mac OS* X option -u is not the same
/U*name*	Undefines any definition currently in effect for the specified symbol; same as the /undefine option.	OFF	-U*name*
/undefine:*name*	Undefines any definition currently in effect for the specified symbol; same as option /U.	OFF	None
/unroll[:*n*]	Tells the compiler the maximum number of times to unroll loops. This is the same as /Qunroll, which is the recommended option to use.	/unroll	-unroll[=*n*]

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/us	Tells the compiler to append an underscore character to external user-defined names; same as the /assume:underscore option.	OFF	-us
/V*string*	Places the text string specified into the object file (.obj) being generated by the compiler; same as the /bintext option.	OFF	None
/[no]vms	Causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).	/novms	-[no]vms
/w	Disables all warning messages; same as specifying option /warn:none or /warn:nogeneral.	OFF	-w
/W*n*	Disables (*n*=0) or enables (*n*=1) all warning messages.	/W1	-W*n*

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/warn:*keyword*	Specifies diagnostic messages to be issued by the compiler.	keywords: alignments general usage nodeclarations noerrors noignore_loc nointerfaces nostderrors notruncated_source nouncalled nounused	-warn *keyword*
/watch[:*keyword*]	Tells the compiler to display certain information to the console output window.	/nowatch	-watch [*keyword*]
/WB	Turns a compile-time bounds check error into a warning.	OFF	-WB
/what	Tells the compiler to display its detailed version string.	OFF	-what
/winapp	Tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.	OFF	None

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
/X	Removes standard directories from the include file search path.	OFF	-X
/Zd	Tells the compiler to generate line numbers and minimal debugging information. Deprecated; use option /debug:minimal.	OFF	None
/Zi or /Z7	Tells the compiler to generate full debugging information in the object file; same as the /debug:full or /debug option.	OFF	-g
/Zl	Prevents any linker search options from being included into the object file; same as the /libdir:none or /nolibdir option.	OFF	None
/Zp[*n*]	Aligns fields of records and components of derived types on the smaller of the size boundary specified or	/Zp16	-Zp[*n*]

Option	Description	Default	Equivalent Option on Linux* OS and Mac OS* X
	the boundary that will naturally align them; same as the /align:rec*n byte* option.		
/Zs	Tells the compiler to perform syntax checking only; same as the /syntax-only option.	OFF	None

Linux* OS and Mac OS* X Quick Reference Guide and Cross Reference

The table in this section summarizes Intel® Fortran compiler options used on Linux* OS and Mac OS* X. Each summary also shows the equivalent compiler options on Windows* OS.

If you want to see the summarized Windows* OS options, see this table.

Some compiler options are only available on systems using certain architectures, as indicated by these labels:

Label	Meaning
i32	The option is available on systems using IA-32 architecture.
i64em	The option is available on systems using Intel® 64 architecture.
i64	The option is available on systems using IA-64 architecture.

If "only" appears in the label, the option is only available on the identified system or architecture.

If no label appears, the option is available on all supported systems and architectures.

For more details on the options, refer to the Alphabetical Compiler Options section.

The Intel® Fortran Compiler includes the Intel® Compiler Option Mapping tool. This tool lets you find equivalent options by specifying compiler option `-map-opts` (Linux OS and Mac OS X) or `/Qmap-opts` (Windows OS).

For information on conventions used in this table, see Conventions.

Quick Reference of Linux OS and Mac OS X Options

The following table summarizes all supported Linux OS and Mac OS X options. It also shows equivalent Windows OS options, if any.

Option	Description	Default	Equivalent Option on Windows* OS
`-1`	Executes at least one iteration of DO loops.	OFF	`/1`
`-66`	Tells the compiler to use FORTRAN 66 semantics.	OFF	None
`-72`, `-80`, `-132`	Treats the statement field of each fixed-form source line as ending in column 72, 80, or 132; same as the `-extend-source` option.	`-72`	`/4L{72|80|132}`
`-align [`*keyword*`]`	Tells the compiler how to align certain data items.	keywords: `nocommons` `nodcommons` `records` `nosequence`	`/align[:`*keyword*`]`
`-allow [no]fpp_comments`	Determines how the fpp preprocessor treats Fortran end-of-line	`-allow fpp_comments`	`/allow:[no]fpp_comments`

Option	Description	Default	Equivalent Option on Windows* OS
	comments in preprocessor directive lines.		
-[no]altparam	Allows alternate syntax (without parentheses) for PARAMETER statements.	-altparam	/[no]altparam
-[no-]ansi-alias	Tells the compiler to assume the program adheres to the Fortran Standard type aliasability rules.	-ansi-alias	/Qansi-alias[-]
-arch *keyword* (i32, i64em)	Tells the compiler to generate optimized code specialized for the processor that executes your program.	varies; see the option description	/arch:*keyword* (i32, i64em)

Option	Description	Default	Equivalent Option on Windows* OS

`-assume` *keyword*	Tells the compiler to make certain assumptions.	keywords:
		`[no]bscc`
		`[no]buffered_io`
		`[no]byterecl`
		`[no]cc_omp`
		`[no]dummy_aliases`
		`[no]ieee_fpe_flags`
		`[no]minus0`
		`[no]old_boz`
		`[no]old_logical_ldio`
		`[no]old_maxminloc`
		`[no]old_unit_star`
		`[no]old_xor`
		`[no]protect_constants`
		`[no]protect_parens`
		`[no]realloc_lhs`
		`[no]source_include`
		`[no]std_mod_proc_name`
		`[no]underscore`
		`[no]2underscores`
		`[no]writeable-strings`
			`/assume:`*keyword*

`-[no]automatic`	Causes all variables to be allocated to the run-time stack; same as the `-auto` option.	`-auto-scalar`	`/[no]automatic`
`-auto-scalar`	Causes allocation of scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL to the run-time stack.	`-auto-scalar`	`/Qauto-scalar`

Option	Description	Default	Equivalent Option on Windows* OS
`-autodouble`	Makes default real and complex variables 8 bytes long; same as the `-real-size 64` option.	OFF	`/Qautodouble`
`-ax`*`processor`* (i32, i64em)	Tells the compiler to generate multiple, processor-specific auto-dispatch code paths for Intel processors if there is a performance benefit.	OFF	`/Qax`*`processor`* (i32, i64em)
`-B`*`dir`*	Specifies a directory that can be used to find include files, libraries, and executables.	OFF	None
`-Bdynamic` (Linux OS only)	Enables dynamic linking of libraries at run time.	OFF	None
`-Bstatic` (Linux OS only)	Enables static linking of a user's library.	OFF	None
`-c`	Causes the compiler to compile to an object file only and not link.	OFF	`/c`
`-CB`	Performs run-time checks on whether array subscript and	OFF	`/CB`

Option	Description	Default	Equivalent Option on Windows* OS
	substring references are within declared bounds; same as the `-check bounds` option.		
`-ccdefault` *keyword*	Specifies the type of carriage control used when a file is displayed at a terminal screen.	`-ccdefault de-fault`	`/ccde-fault:`*keyword*
`-check` [*keyword*]	Checks for certain conditions at run time.	`-nocheck`	`/check`[`:`*keyword*]
`-cm`	Disables all messages about questionable programming practices; same as specifying option `-warn nousage`.	OFF	`/cm`
`-common-args`	Tells the compiler that dummy (formal) arguments to procedures share memory locations with other dummy arguments or with COMMON variables that are assigned. This option is the same as `-assume dummy_aliases`.	OFF	`/Qcommon-args`

Option	Description	Default	Equivalent Option on Windows* OS
`-[no-]complex-limited-range`	Enables the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX.	`-no-complex-limited-range`	`/Qcomplex-limited-range[-]`
`-convert` *keyword*	Specifies the format of unformatted files containing numeric data.	`-convert native`	`/convert:`*keyword*
`-cpp`	Runs the Fortran preprocessor on source files prior to compilation.	OFF	`/Qcpp`
`-CU`	Enables run-time checking for uninitialized variables. This option is the same as `-check uninit`.	OFF	`/CU`
`-cxxlib[=`*dir* `]`	Tells the compiler to link using the C++ run-time libraries provided by gcc.	`-no-cxxlib`	None
`-cxxlib-nostd`	Prevents the compiler from linking with the standard C++ library.	`-no-cxxlib`	None

Option	Description	Default	Equivalent Option on Windows* OS
`-D`*`name`* [=*`value`*]	Defines a symbol name that can be associated with an optional value.	`-noD`	`/D`*`name`* [=*`value`*]
`-[no]d-lines`	Compiles debugging statements indicated by the letter D in column 1 of the source code.	`-nod-lines`	`/[no]d-lines`or `/Qd-lines`
`-DD`	Compiles debugging statements indicated by the letter D in column 1 of the source code; same as the `-d-lines` option.	`-nod-lines`	`/d-lines`
`-debug` *`keyword`*	Specifies settings that enhance debugging.	`-debug none`	`/debug:`*`keyword`* Note: the Windows option takes different *`keyword`* s
`-debug-parameters` [*`keyword`*]	Tells the compiler to generate debug information for PARAMETERs used in a program.	`-nodebug-parame-ters`	`/debug-parame-ters`[:*`keyword`*]
`-diag-`*`type diag-list`*	Controls the display of diagnostic information.	OFF	`/Qdiag-`*`type`* : *`diag-list`*
`-diag-dump`	Tells the compiler to print all enabled diagnostic messages and stop compilation.	OFF	`/Qdiag-dump`

Option	Description	Default	Equivalent Option on Windows* OS
`-diag-enable sc-include` (i32, i64em)	Tells the Source Checker to analyze include files and source files when issuing diagnostic message. This option is equivalent to `-diag-enable sv-include`.	OFF	`/Qdiag-enable:sc-include` (i32, i64em)
`-diag-enable sc-parallel` (i32, i64em)	Enables analysis of parallelization in source code (parallel lint diagnostics).	OFF	`/Qdiag-enable:sc-parallel` (i32, i64em)
`-diag-error-limit` *n*	Specifies the maximum number of errors allowed before compilation stops.	`-diag-error-limit 30`	`/Qdiag-error-limit:`*n*
`-diag-file`[= *file*]	Causes the results of diagnostic analysis to be output to a file.	OFF	`/Qdiag-file[:`*file*`]`
`-diag-file-append`[= *file*]	Causes the results of diagnostic analysis to be appended to a file.	OFF	`/Qdiag-file-append[:`*file* `]`
`-[no-]diag-id-numbers`	Tells the compiler to display diagnostic messages by using their ID number values.	`-diag-id-numbers`	`/Qdiag-id-numbers[-]`

Option	Description	Default	Equivalent Option on Windows* OS
`-diag-once` *id*[,*id*,...]	Tells the compiler to issue one or more diagnostic messages only once	OFF	`/Qdiag-once:`*id*[,*id*,...]
`-double-size` *size*	Defines the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX variables.	`-double-size 64`	`/double-size:`*size*
`-dps`	Specifies that the alternate syntax for PARAMETER statements is allowed; same as the `-altparam` option.	`-dps`	`/Qdps`
`-dryrun`	Specifies that driver tool commands should be shown but not executed.	OFF	None
`-dumpmachine`	Displays the target machine and operating system configuration.	OFF	None
`-dynamic-linker`*file* (Linux OS only)	Specifies a dynamic linker in *file* other than the default.	OFF	None
`-dynamiclib` (i32, i64em; Mac OS X only)	Invokes the *libtool* command to generate dynamic libraries.	OFF	None

Option	Description	Default	Equivalent Option on Windows* OS
`-dyncom "com-mon1,common2,..."`	Enables dynamic allocation of common blocks at run time.	OFF	`/Qdyncom "com-mon1,common2,..."`
`-E`	Causes the Fortran preprocessor to send output to stdout.	OFF	`/E`
`-e03, -e95, -e90`	Causes the compiler to issue errors instead of warnings for nonstandard Fortran; same as the `-warn stderrors` option.	OFF	None
`-EP`	Causes the Fortran preprocessor to send output to stdout, omitting #line directives.	OFF	`/EP`
`-error-limit` *n*	Specifies the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line; same as `-diag-error-limit`.	`-error-limit 30`	`/error-limit:`*n*
`-extend-source` *size*	Specifies the length of the statement field in a fixed-form source file.	`-extend-source 72`	`/extend-source:`*size*

Option	Description	Default	Equivalent Option on Windows* OS
`-f66`	Tells the compiler to use FORTRAN 66 semantics.	OFF	`/f66`
`-[no]f77rtl`	Tells the compiler to use FORTRAN 77 run-time behavior.	OFF	`/[no]f77rtl`
`-f[no-]alias`	Determines whether aliasing should be assumed in the program.	ON	None
`-falign-functions`[=*n*] (i32, i64em)	Tells the compiler to align functions on an optimal byte boundary.	`-no-falign-functions`	`/Qfnalign[:`*n*`]` (i32, i64em)
`-falign-stack`[=*mode*] (i32 only)	Tells the compiler to align functions on an optimal byte boundary.	`-falign-stack=default`	None
`-fast`	Maximizes speed across the entire program.	OFF	`/fast`
`-[no-]fast-transcendentals`	Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.	ON	`/Qfast-transcendentals[-]`
`-fcode-asm`	Produces an assembly file with optional machine code annotations.	OFF	`/FAc`

Option	Description	Default	Equivalent Option on Windows* OS
`-f[no-]exceptions`	Enables exception handling table generation.	`-fno-exceptions`	None
`-f[no-]fnalias`	Specifies that aliasing should be assumed within functions.	OFF	`-ffnalias`
`-FI`	Specifies source files are in fixed format; same as the `-fixed` option.	determined by file suffix	`/FI`
`-f[no-]inline`	Tells the compiler to inline functions declared with cDEC$ ATTRIBUTES FORCEINLINE.	`-fno-inline`	None
`-f[no-]inline-functions`	Enables function inlining for single file compilation.	`-finline-functions`	`/Ob2`
`-finline-limit=`*n*	Lets you specify the maximum size of a function to be inlined.	OFF	None
`-f[no-]instrument-functions`	Determines whether function entry and exit points are instrumented.	`-fno-instrument-functions`	`/Qinstrument-functions[-]`
`-[no]fixed`	Specifies source files are in fixed format.	determined by file suffix	`/[no]fixed`

Option	Description	Default	Equivalent Option on Windows* OS
`-f[no-]keep-static-consts`	Tells the compiler to preserve allocation of variables that are not referenced in the source.	`-fno-keep-static-consts`	`/Qkeep-static-consts[-]`
`-[no]fltconsistency`	Enables improved floating-point consistency.	OFF	`/[no]fltconsistency`
`-[no-]fma` (i64 only; Linux OS only)	Enables the combining of floating-point multiplies and add/subtract operations.	`-fma`	`/Qfma[-]` (i64 only)
`-f[no-]math-errno`	Tells the compiler that *errno* can be reliably tested after calls to standard math library functions.	`-fno-math-errno`	None
`-fminshared`	Tells the compiler to treat a compilation unit as a component of a main program and not to link it as a shareable object.	OFF	None
`-[no-]fnsplit` (i64 only; Linux OS only)	Enables function splitting.	OFF	`/Qfnsplit[-]` (i32, i64)

Option	Description	Default	Equivalent Option on Windows* OS
`-f[no-]omit-frame-pointer` (i32, i64em)	Determines whether EBP is used as a general-purpose register in optimizations. This is the same as specifying option `-fp`, which is deprecated.	`-fomit-frame-pointer` (unless option `-O0` or `-g` is specified)	`/Oy[-]` (i32 only)
`-fp-model` *keyword*	Controls the semantics of floating-point calculations.	`-fp-model fast`	`/fp:`*keyword*
`-[no-]fp-port`	Rounds floating-point results after floating-point operations, so rounding to user-declared precision happens at assignments and type conversions (some impact on speed).	`-no-fp-port`	`/Qfp-port[-]`
`-[no-]fp-relaxed` (i64 only; Linux OS only)	Enables use of faster but slightly less accurate code sequences for math functions, such as divide and sqrt.	`-no-fp-relaxed`	`/Qfp-relaxed[-]` (i64 only)

Option	Description	Default	Equivalent Option on Windows* OS
`-fp-specula-tion=`*mode*	Tells the compiler the mode in which to speculate on floating-point operations.	`-fp-specula-tion=fast`	`/Qfp-specula-tion:`*mode*
`-fp-stack-check` (i32, i64em)	Generates extra code after every function call to ensure that the FP (floating-point) stack is in the expected state.	OFF	`/Qfp-stack-check` (i32, i64em)
`-[no]fpconstant`	Tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.	OFF	`/[no]fpconstant`
`-fpe`*n*	Specifies the floating-point exception handling level for the main program at run-time.	`-fpe3`	`/fpe:`*n*
`-fpe-all=`*n*	Specifies the floating-point exception handling level for each routine at run-time.	`-fpe-all3`	`/fpe-all:`*n*
`-f[no-]pic`, `-fPIC`	Generates position-independent code.	`-fno-pic`	None

Option	Description	Default	Equivalent Option on Windows* OS
`-fpie` (Linux OS only)	Tells the compiler to generate position-independent code.	OFF	None
`-fpp[`*`n`*`]` or `-fpp[="`*`option`*`"]`	Runs the Fortran preprocessor on source files prior to compilation.	`-nofpp`	`/fpp[`*`n`*`]` or `/fpp[="`*`option`*`"]`
`-fpscomp` [*`keyword`*]	Specifies compatibility with Microsoft* Fortran PowerStation or Intel® Fortran.	`-fpscomp libs`	`/fpscomp[:`*`keyword`*`]`
`-FR`	Specifies source files are in free format; same as the `-free` option.	determined by file suffix	`/FR`
`-fr32` (i64 only; Linux OS only)	Disables use of high floating-point registers.	OFF	None
`-[no]free`	Specifies source files are in free format.	determined by file suffix	`/[no]free`
`-fsource-asm`	Produces an assembly file with optional source code annotations.	OFF	`/FAs`
`-f[no-]stack-security-check`	Determines whether the compiler generates code that detects some buffer	`-fno-stack-security-check`	`/GS[-]`

Option	Description	Default	Equivalent Option on Windows* OS
	overruns; same as `-f[no-]stack-protector`.		
`-fsyntax-only`	Specifies that the source file should be checked only for correct syntax; same as `-syntax-only`.	OFF	None
`-ftrapuv`	Initializes stack local variables to an unusual value.	OFF	`/Qtrapuv`
`-[no-]ftz`	Flushes denormal results to zero.	i64: `-no-ftz` i32, i64em: `-ftz`	`/Qftz[-]`
`-[no-]func-groups` (i32, i64em; Linux OS only)	Enables or disables function grouping if profiling information is enabled. This option is deprecated, use `-prof-func-groups`.	`-no-func-groups`	None
`-funroll-loops`	Tells the compiler to unroll user loops based on the default optimization heuristics; same as `-unroll`, which is the recommended option.	`-funroll-loops`	`/Qunroll`

Option	Description	Default	Equivalent Option on Windows* OS
`-fverbose-asm`	Produces an assembly file with compiler comments, including options and version information.	`-fno-verbose-asm`	None
`-fvisibility=`*keyword* `-fvisibility-`*keyword*`=` *file*	Specifies the default visibility for global symbols; the 2nd form indicates symbols in a file.	`-fvisibility=default`	None
`-g`	Produces symbolic debug information in the object file.	OFF	`/Zi, /Z7`
`-gdwarf2`	Enables generation of debug information using the DWARF2 format.	OFF	None
`-gen-interfaces` [*`[no]source`*]	Tells the compiler to generate an interface block for each routine in a source file.	`-nogen-interfaces`	`/gen-interfaces`[:*`[no]source`*]
`-[no-]global-hoist`	Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.	`-global-hoist`	`/Qglobal-hoist[-]`

Option	Description	Default	Equivalent Option on Windows* OS
`-heap-arrays [size]`	Puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.	`-no-heap-arrays`	`/heap-arrays[:size]`
`-help [category]`	Displays the list of compiler options.	OFF	`/help [category]`
`-Idir`	Specifies a directory to add to the include path.	OFF	`/Idir`
`-i-dynamic`	Links Intel-provided libraries dynamically. This is a deprecated option; use `-shared-intel`.	OFF	None
`-i-static`	Links Intel-provided libraries statically. This is a deprecated option; use `-static-intel`.	OFF	None
`-i{2|4|8}`	Specifies the default KIND for integer and logical variables; same as the `-integer-size` option.	`-i4`	`/4I{2|4|8}`
`-idirafterdir`	Adds a directory to the second include file search path.	OFF	None

Option	Description	Default	Equivalent Option on Windows* OS
`-implicitnone`	Sets the default type of a variable to undefined; same as option `warn declarations`.	OFF	`/4Yd`
`-inline-debug-info`	Produces enhanced source position information for inlined code.	OFF	`/Qinline-debug-info`
`-inline-factor=`*n*	Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.	`-no-inline-factor`	`/Qinline-factor=`*n*
`-inline-forceinline`	Specifies that an inline routine should be inlined whenever the compiler can do so.	OFF	`/Qinline-forceinline`
`-inline-level=`*n*	Specifies the level of inline function expansion. *n* = 0, 1, or 2.	`-inline-level=2` if `-O2` is in effect `-inline-level=0` if `-O0` is specified	`/Ob`*n*
`-inline-max-per-compile=`*n*	Specifies the maximum number of times inlining may be applied to an entire compilation unit.	`-no-inline-max-per-compile`	`/Qinline-max-per-compile=`*n*

Option	Description	Default	Equivalent Option on Windows* OS
`-inline-max-per-routine=`*n*	Specifies the maximum number of times the inliner may inline into a particular routine.	`-no-inline-max-per-routine`	`/Qinline-max-per-routine=`*n*
`-inline-max-size=`*n*	Specifies the lower limit for the size of what the inliner considers to be a large routine.	`-no-inline-max-size`	`/Qinline-max-size=`*n*
`-inline-max-total-size=`*n*	Specifies how much larger a routine can normally grow when inline expansion is performed.	`-no-inline-max-total-size`	`/Qinline-max-total-size=`*n*
`-inline-min-size=`*n*	Specifies the upper limit for the size of what the inliner considers to be a small routine.	`-no-inline-min-size`	`/Qinline-min-size=`*n*
`-[no]intconstant`	Tells the compiler to use FORTRAN 77 semantics to determine the KIND for integer constants.	`-nointconstant`	`/[no]intconstant`
`-integer-size` *size*	Specifies the default KIND for integer and logical variables.	`-integer-size 32`	`/integer-size:`*size*

Option	Description	Default	Equivalent Option on Windows* OS
`-[no-]ip`	Enables additional single-file interprocedural optimizations.	OFF	`/Qip[-]`
`-ip-no-inlining`	Disables full and partial inlining enabled by `-ip`.	OFF	`/Qip-no-inlining`
`-ip-no-pinlining`	Disables partial inlining.	OFF	`/Qip-no-pinlining`
`-IPF-flt-eval-method0` (i64 only; Linux OS only)	Tells the compiler to evaluate the expressions involving floating-point operands in the precision indicated by the variable types declared in the program. Deprecated.	OFF	`/QIPF-flt-eval-method0` (i64 only)
`-IPF-fltacc` (i64 only; Linux OS only)	Tells the compiler to apply optimizations that affect floating-point accuracy. Deprecated.	`-no-IPF-fltacc`	`/QIPF-fltacc` (i64 only)
`-IPF-fma` (i64 only; Linux OS only)	Enables the combining of floating-point multiplies and add/subtract	`-IPF-fma`	`/QIPF-fma` (i64 only)

Option	Description	Default	Equivalent Option on Windows* OS
	operations. Deprecated; use `-fma`.		
`-IPF-fp-relaxed` (i64 only; Linux OS only)	Enables use of faster but slightly less accurate code sequences for math functions, such as divide and sqrt. Deprecated; use `-fp-relaxed`.	`-no-IPF-fp-relaxed`	`/QIPF-fp-relaxed` (i64 only)
`-ipo`[*n*]	Enables multifile IP optimizations between files.	OFF	`/Qipo`[*n*]
`-ipo-c`	Generates a multifile object file that can be used in further link steps.	OFF	`/Qipo-c`
`-ipo-jobs`*n*	Specifies the number of commands to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).	`-ipo-jobs1`	`/Qipo-jobs:`*n*
`-ipo-S`	Generates a multifile assembly file that can be used in further link steps.	OFF	`/Qipo-S`
`-ipo-separate` (Linux OS only)	Generates one object file per source file.	OFF	`/Qipo-separate`

Option	Description	Default	Equivalent Option on Windows* OS
-isystem*dir*	Specifies a directory to add to the start of the system include path.	OFF	None
-ivdep-parallel (i64 only; Linux OS only)	Tells the compiler that there is no loop-carried memory dependency in any loop following an IVDEP directive.	OFF	/Qivdep-parallel (i64 only)
-l*string*	Tells the linker to search for a specified library when linking.	OFF	None
-L*dir*	Tells the linker where to search for libraries before searching the standard directories.	OFF	None
-[no]logo	Displays compiler version information.	-nologo	/[no]logo
-lowercase	Causes the compiler to ignore case differences in identifiers and to convert external names to lowercase; same as the -names lowercase option.	-lowercase	/Qlowercase
-m[*processor*] (i32, i64em)	Tells the compiler to generate optimized code specialized for	varies; see option description	/arch

Option	Description	Default	Equivalent Option on Windows* OS
	the processor that executes your program.		
`-m32, -m64` (i32, i64em)	Tells the compiler to generate code for IA-32 architecture or Intel® 64 architecture, respectively.	OFF	None
`-map-opts` (Linux OS only)	Maps one or more Linux* OS compiler options to their equivalent on a Windows* system (or vice versa).	OFF	`/Qmap-opts`
`-march=`*`processor`* (i32, i64em; Linux OS only)	Tells the compiler to generate code for a specified processor.	i32: OFF i64em: `-march=pentium4`	None
`-mcmodel=`*`mem_model`* (i64em only; Linux OS only)	Tells the compiler to use a specific memory model to generate code and store data.	`-mcmodel=small`	None
`-mdynamic-no-pic` (i32 only; Mac OS X only)	Generates code that is not position-independent but has position-independent external references.	OFF	None
`-mieee-fp`	Tells the compiler to use IEEE floating point comparisons.	OFF	`/fltconsistency`

Option	Description	Default	Equivalent Option on Windows* OS
	This is the same as specifying option `-fltconsistency` or `-mp`.		
`-minstruc-tion=[no]movbe` (i32, i64em)	Determines whether MOVBE instructions are generated for Intel processors.	OFF	/Qinstruction:[no]movbe (i32, i64em)
`-mixed_str_len_arg`	Tells the compiler that the hidden length passed for a character argument is to be placed immediately after its corresponding character argument in the argument list.	OFF	`/iface:mixed_str_len_arg`
`-mkl[=`*lib*	Tells the compiler to link to certain parts of the Intel® Math Kernel Library.	OFF	`/Qmkl[=`*lib*
`-module` *path*	Specifies the directory where module files should be placed when created and where they should be searched for.	OFF	`/module:`*path*
`-mp`	Enables improved floating-point consistency.	OFF	`/Op`

Option	Description	Default	Equivalent Option on Windows* OS
`-mp1`	Improves floating-point precision and consistency.	OFF	`/Qprec`
`-m[no-]relax` (i64 only)	Determines whether the compiler passes linker option `-relax` to the linker.	`-mno-relax`	None
`-mtune=`*`processor`*	Performs optimizations for a particular processor. `-mtune=itanium2` is equivalent to `/G2`.	i32: `-mtune=pentium4` i64: `-mtune=itanium2-p9000`	None
`-multiple-processes=` *`n`*	Creates multiple processes that can be used to compile large numbers of source files at the same time.	OFF	`/MP:` *`n`*
`-names` *`keyword`*	Specifies how source code identifiers and external names are interpreted.	`-names lowercase`	`/names:`*`keyword`*
`-nbs`	Tells the compiler to treat the backslash character (\) as a normal character in character literals; same as the `-assume nobscc` option.	`-nbs`	`/nbs`

Option	Description	Default	Equivalent Option on Windows* OS
-no-bss-init	Tells the compiler to place in the DATA section any variables explicitly initialized with zeros.	OFF	/Qno-bss-init
-nodefaultlibs	Prevents the compiler from using standard libraries when linking.	OFF	None
-nodefine	Specifies that all preprocessor definitions apply only to fpp and not to Intel® Fortran conditional compilation directives.	OFF	/nodefine
-nofor-main	Specifies the main program is not written in Fortran, and prevents the compiler from linking for_main.o into applications.	OFF	None
-noinclude	Prevents the compiler from searching in a directory previously added to the include path for files specified in an INCLUDE statement.	OFF	/noinclude

Option	Description	Default	Equivalent Option on Windows* OS
`-nolib-inline`	Disables inline expansion of standard library or intrinsic functions.	OFF	None
`-nostartfiles`	Prevents the compiler from using standard startup files when linking.	OFF	None
`-nostdinc`	Removes standard directories from the include file search path; same as the `-X` option.	OFF	None
`-nostdlib`	Prevents the compiler from using standard libraries and startup files when linking.	OFF	None
`-nus`	Disables appending an underscore to external user-defined names; same as the `-assume nounder-score` option.	OFF	None
`-o`*`file`*	Specifies the name for an output file.	OFF	None
`-O`[*n*]	Specifies the code optimization for applications.	`-O2`	`/O`[*n*]
`-O0`	Disables all optimizations.	OFF	`/Od`

Option	Description	Default	Equivalent Option on Windows* OS
-onetrip	Executes at least one iteration of DO loops.	OFF	/onetrip
-openmp	Enables the parallelizer to generate multithreaded code based on OpenMP* directives.	OFF	/Qopenmp
-openmp-lib *type* (Linux OS only)	Lets you specify an OpenMP* run-time library to use for linking.	-openmp-lib legacy	/Qopenmp-lib:*type*
-openmp-link *library*	Controls whether the compiler links to static or dynamic OpenMP run-time libraries.	-openmp-link dynamic	/Qopenmp-link:*library*
-openmp-profile (Linux OS only)	Enables analysis of OpenMP* applications.	OFF	/Qopenmp-profile
-openmp-report[*n*]	Controls the OpenMP parallelizer's level of diagnostic messages.	-openmp-report1	/Qopenmp-report[*n*]
-openmp-stubs	Enables compilation of OpenMP programs in sequential mode.	OFF	/Qopenmp-stubs
-openmp-threadprivate *type* (Linux OS only)	Lets you specify an OpenMP* threadprivate implementation.	-openmp-threadprivate legacy	/Qopenmp-threadprivate:*type*

Option	Description	Default	Equivalent Option on Windows* OS
`-opt-block-factor=`*n*	Lets you specify a loop blocking factor.	OFF	`/Qopt-block-factor:`*n*
`-opt-jump-tables=`*keyword*	Enables or disables generation of jump tables for switch statements.	`-opt-jump-tables=default`	`/Qopt-jump-tables:`*keyword*
`-[no-]opt-loadpair` (i64 only; Linux OS only)	Enables or disables loadpair optimization.	`-no-opt-loadpair`	`/Qopt-loadpair[-]` (i64 only)
`-opt-malloc-options=`*n* (i32, i64em)	Lets you specify an alternate algorithm for malloc().	`-opt-malloc-options=0`	None
`-opt-mem-bandwidth`*n* (i64 only; Linux OS only)	Enables performance tuning and heuristics that control memory bandwidth use among processors.	`-opt-mem-bandwidth0` for serial compilation; `-opt-mem-bandwidth1` for parallel compilation	`/Qopt-mem-bandwidth`*n* (i64 only)
`-[no-]opt-mod-versioning` (i64 only; Linux OS only)	Enables or disables versioning of modulo operations for certain types of operands.	`-no-opt-mod-versioning`	`/Qopt-mod-versioning[-]` (i64 only)
`-[no-]opt-multi-version-aggressive` (i32, i64em)	Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.	`-no-opt-multi-version-aggressive`	`/Qopt-multi-version-aggressive[-]` (i32, i64em)

Option	Description	Default	Equivalent Option on Windows* OS
`-opt-prefetch`[=*n*]	Enables prefetch insertion optimization.	i64: `-opt-prefetch` i32, i64em: `-no-opt-prefetch`	`/Qopt-prefetch`[:*n*]
`-[no-]opt-prefetch-initial-values` (i64 only; Linux OS only)	Enables or disables prefetches that are issued before a loop is entered.	`-opt-prefetch-initial-values`	`/Qopt-prefetch-initial-values[-]` (i64 only)
`-[no-]opt-prefetch-issue-excl-hint` (i64 only; Linux OS only)	Determines whether the compiler issues prefetches for stores with exclusive hint.	`-no-opt-prefetch-issue-excl-hint`	`/Qopt-prefetch-issue-excl-hint[-]` (i64 only)
`-[no-]opt-prefetch-next-iteration` (i64 only; Linux OS only)	Enables or disables prefetches for a memory access in the next iteration of a loop.	`-opt-prefetch-next-iteration`	`/Qopt-prefetch-next-iteration[-]`[:*n*] (i64 only)
`-opt-ra-region-strategy`[=*keyword*] (i32, i64em)	Selects the method that the register allocator uses to partition each routine into regions.	`-opt-ra-region-strategy=default`	`/Qopt-ra-region-strategy`[:*keyword*] (i32, i64em)
`-opt-report` [*n*]	Tells the compiler to generate an optimization report to stderr.	`-opt-report 2`	`/Qopt-report[:`*n*]
`-opt-report-file=`*file*	Specifies the name for an optimization report.	OFF	`/Qopt-report-file:`*file*

Option	Description	Default	Equivalent Option on Windows* OS
`-opt-report-help`	Displays the optimizer phases available for report generation.	OFF	`/Qopt-report-help`
`-opt-report-phase=`*`phase`*	Specifies an optimizer phase to use when optimization reports are generated.	OFF	`/Qopt-report-phase:`*`phase`*
`-opt-report-routine=`*`string`*	Tells the compiler to generate reports on the routines containing specified text.	OFF	`/Qopt-report-routine:`*`string`*
`-opt-streaming-stores` *`keyword`* (i32, i64em)	Enables generation of streaming stores for optimization.	`-opt-streaming-stores auto`	`/Qopt-streaming-stores:`*`keyword`* (i32, i64em)
`-[no-]opt-subscript-in-range` (i32, i64em)	Determines whether the compiler assumes no overflows in the intermediate computation of subscript expressions in loops.	`-no-opt-subscript-in-range`	`/Qopt-subscript-in-range[-]` (i32, i64em)
`-p`	Compiles and links for function profiling with gprof(1).	OFF	None
`-P`	Causes the Fortran preprocessor to send output to a file, which is named by	OFF	`/P`

Option	Description	Default	Equivalent Option on Windows* OS
	default; same as the `-preprocess-only` option.		
`-[no]pad`	Enables the changing of the variable and array memory layout.	OFF	`/Qpad[-]`
`-[no]pad-source`	Specifies padding for fixed-form source records.	OFF	`/[no]pad-source` or `/Qpad-source[-]`
`-par-affini-ty=[`*`modifier`*`,...]` *`type`*`[,`*`permute`*`] [,`*`offset`*`]` (Linux* OS only)	Specifies thread affinity.	OFF	`/Qpar-affini-ty:[`*`modifier`*`,...]` *`type`*`[,`*`permute`*`][,`*`offset`*`]`
`-par-num-threads=`*`n`*	Specifies the number of threads to use in a parallel region.	OFF	`/Qpar-num-threads:`*`n`*
`-par-report[`*`n`*`]`	Controls the diagnostic information reported by the auto-parallelizer.	`-par-report1`	`/Qpar-report[`*`n`*`]`
`-[no-]par-run-time-control`	Generates code to perform run-time checks for loops that have symbolic loop bounds.	`-no-par-runtime-control`	`/Qpar-runtime-control[-]`
`-par-sched-ule-`*`keyword`* `[=`*`n`*`]`	Specifies a scheduling algorithm for DO loop iterations.	OFF	`/Qpar-sched-ule-`*`keyword`* `[[:]`*`n`*`]`

Option	Description	Default	Equivalent Option on Windows* OS
`-par-threshold[`*n*`]`	Sets a threshold for the auto-parallelization of loops.	`-par-threshold100`	`/Qpar-thresh-old[[:]`*n*`]`
`-parallel`	Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.	OFF	`/Qparallel`
`-pc`*n* (i32, i64em)	Enables control of floating-point significand precision.	`-pc80`	`/Qpc`*n* (i32, i64em)
`-pg`	Compiles and links for function profiling with gprof(1); same as the `-p` option.	OFF	None
`-pie` (Linux OS only)	Produces a position-independent executable on processors that support it.	OFF	None
`-[no-]prec-div`	Improves precision of floating-point divides.	`-prec-div`	`/Qprec-div[-]`
`-[no-]prec-sqrt` (i32, i64em)	Improves precision of square root implementations.	`-no-prec-sqrt`	`/Qprec-sqrt[-]` (i32, i64em)

Option	Description	Default	Equivalent Option on Windows* OS
`-prefetch`	Enables prefetch insertion optimization. Deprecated; use `-opt-prefetch`.	i64: `-prefetch` i32, i64em: `-no-prefetch`	`/Qprefetch`
`-preprocess-only`	Causes the Fortran preprocessor to send output to a file, which is named by default; same as the `-P` option.	OFF	`/preprocess-only`
`-print-multi-lib`	Prints information about where system libraries should be found.	OFF	None
`-[no-]prof-data-order` (Linux OS only)	Enables or disables data ordering if profiling information is enabled.	`-no-prof-data-order`	`/Qprof-data-order[-]`
`-prof-dir` *dir*	Specifies a directory for profiling information output files.	OFF	`/Qprof-dir` *dir*
`-prof-file` *file*	Specifies a file name for the profiling summary file.	OFF	`/Qprof-file` *file*
`-[no-]prof-func-groups` (i32, i64em; Linux OS only)	Enables or disables function grouping if profiling information is enabled.	`-no-prof-func-groups`	None

Option	Description	Default	Equivalent Option on Windows* OS
`-[no-]prof-func-order` (Linux OS only)	Enables or disables function ordering if profiling information is enabled.	`-no-prof-func-order`	`/Qprof-func-order[-]`
`-prof-gen`[`=`*keyword*]	Produces an instrumented object file that can be used in profile-guided optimization.	`-[no-]prof-gen`	`/Qprof-gen`[`:`*keyword*
`-prof-genx`	Produces an instrumented object file that includes extra source position information. Deprecated; use `-prof-gen=srcpos`.	OFF	`/Qprof-genx`
`-prof-hotness-threshold=`*n* (Linux OS only)	Lets you set the hotness threshold for function grouping and function ordering.	OFF	`/Qprof-hotness-threshold:`*n*
`-[no-]prof-src-dir`	Determines whether directory information of the source file under compilation is considered when looking up profile data records.	`-prof-src-dir`	`/Qprof-src-dir[-]`

Option	Description	Default	Equivalent Option on Windows* OS
-prof-src-root=*dir*	Lets you use relative directory paths when looking up profile data and specifies a directory as the base.	OFF	/Qprof-src-root:*dir*
-prof-src-root-cwd	Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.	OFF	/Qprof-src-root-cwd
-prof-use[=*arg*]	Enables the use of profiling information during optimization.	-no-prof-use	/Qprof-use[:*arg*]
-Qinstall *dir*	Specifies the root directory where the compiler installation was performed.	OFF	None
-Qloca-tion,*string*,*dir*	Specifies a directory as the location of the specified tool in *string* .	OFF	/Qloca-tion,*string*,*dir*
-Qop-tion,*string*,*options*	Passes *options* to the specified tool in *string*.	OFF	/Qop-tion,*string*,*options*
-r8, -r16	Specifies the default KIND for real and complex variables. -r8 is the same as	OFF	/4R8, /4R16

Option	Description	Default	Equivalent Option on Windows* OS
	`/real-size:64`. `-r16` is the same as `/real-size:128`.		
`-rcd` (i32, i64em)	Enables fast float-to-integer conversions.	OFF	`/Qrcd` (i32, i64em)
`-rct` (i32, i64em)	Sets the internal FPU rounding control to Truncate.	OFF	`/Qrct` (i32, i64em)
`-real-size` *size*	Specifies the default KIND for real variables.	`-real-size 32`	`/real-size:`*size*
`-recursive`	Tells the compiler that all routines should be compiled for possible recursive execution.	`-norecursive`	`/recursive`
`-reentrancy` *keyword*	Tells the compiler to generate reentrant code to support a multithreaded application.	`-noreentrancy`	`/reentrancy:`*keyword*
`-S`	Causes the compiler to compile to an assembly file (.s) only and not link; same as options `/Fa` and `/asmfile`.	OFF	`/S`

Option	Description	Default	Equivalent Option on Windows* OS
-safe-cray-ptr	Tells the compiler that Cray* pointers do not alias other variables.	OFF	/Qsafe-cray-ptr
-save	Causes variables to be placed in static memory.	-auto-scalar	/Qsave
-[no-]save-temps	Tells the compiler to save intermediate files created during compilation.	-no-save-temps	/Qsave-temps[-]
-[no-]scalar-rep (i32 only)	Enables scalar replacement performed during loop transformation (requires -O3).	-no-scalar-rep	/Qscalar-rep[-] (i32 only)
-shared (Linux OS only)	Tells the compiler to produce a dynamic shared object instead of an executable.	OFF	None
-shared-intel	Links Intel-provided libraries dynamically.	OFF	None
-shared-libgcc (Linux OS only)	Links the GNU libgcc library dynamically.	-shared-libgcc	None
-[no-]sox (Linux OS only)	Tells the compiler to save the compilation options and version number in the Linux OS executable.	-no-sox	/Qsox[-]

Option	Description	Default	Equivalent Option on Windows* OS
`-stand` *keyword*	Causes the compiler to issue compile-time messages for nonstandard language elements.	`-nostand`	`/stand:`*keyword*
`-static` (Linux OS only)	Prevents linking with shared libraries.	`-static`	`/static`
`-staticlib` (i32, i64em; Mac OS X only)	Invokes the libtool command to generate static libraries.	OFF	None
`-static-intel`	Links Intel-provided libraries statically.	OFF	None
`-static-libgcc` (Linux OS only)	Links the GNU libgcc library statically.	OFF	None
`-std90`	Causes the compiler to issue messages for language elements that are not standard in Fortran 90; same as `-stand f90`.	OFF	`/stand:f90`
`-std95`	Causes the compiler to issue messages for language elements that are not standard in Fortran 95; same as `-stand f95`.	OFF	`/stand:f95`
`-std03`	Causes the compiler to issue messages for language elements	OFF	`/stand:f03`

Option	Description	Default	Equivalent Option on Windows* OS
	that are not standard in Fortran 2003; same as `-std` or `-stand f03`.		
`-syntax-only`	Specifies that the source file should be checked only for correct syntax.	OFF	`/syntax-only`
`-T` *file* (Linux OS only)	Tells the linker to read link commands from the specified *file*.	OFF	None
`-tcheck` (Linux OS only)	Enables analysis of threaded applications.	OFF	`/Qtcheck`
`-tcollect` [*lib*] (Linux OS only)	Inserts instrumentation probes calling the Intel(R) Trace Collector API.	OFF	`/Qtcollect`[=*lib*]
`-tcollect-filter` [*file*] (Linux OS only)	Lets you enable or disable the instrumentation of specified functions.	OFF	`/Qtcollect-filter`[=*file*]
`-Tf` *file*	Tells the compiler to compile the file as a Fortran source file.	OFF	`/Tf` *file*

Option	Description	Default	Equivalent Option on Windows* OS
`-[no]threads`	Tells the linker to search for unresolved references in a multithreaded run-time library.	i32, i64: `-nothreads` i64em: `-threads`	`/[no]threads`
`-tprofile` (Linux OS only)	Generates instrumentation to analyze multi-threading performance.	OFF	`/Qtprofile`
`-[no]traceback`	Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.	`-notraceback`	`/[no]traceback`
`-tune` *keyword* (i32, i64em)	Determines the version of the architecture for which the compiler generates instructions.	`-tune pn4`	`/tune:`*keyword* (i32, i64em)
`-u`	Enables error messages about any undeclared symbols; same as the `-warn declarations` option.	OFF	None Note: the Windows option `/u` is not the same

Option	Description	Default	Equivalent Option on Windows* OS
-U*name*	Undefines any definition currently in effect for the specified symbol.	OFF	/U*name*
-unroll[*n*]	Tells the compiler the maximum number of times to unroll loops. -unroll is the same as option -funroll-loops.	-unroll	/unroll[:*n*]
-[no-]unroll-aggressive (i32, i64em)	Determines whether the compiler uses more aggressive unrolling for certain loops.	-no-unroll-aggressive	/Qunroll-aggressive[-] (i32, i64em)
-uppercase	Causes the compiler to ignore case differences in identifiers and to convert external names to uppercase; same as the -names uppercase option.	OFF	/Quppercase
-us	Tells the compiler to append an underscore character to external user-defined names; same as the -assume underscore option.	-us	/us

Option	Description	Default	Equivalent Option on Windows* OS
`-[no-]use-asm`	Tells the compiler to produce objects through the assembler.	`-no-use-asm`	`/Quse-asm[-]` (i32 only)
`-v` [*file*]	Tells the driver that tool commands should be shown and executed.	OFF	None
`-V`	Displays the compiler version information; same as the `-logo` option.	OFF	None
`-[no-]vec` (i32, i64em)	Enables or disables vectorization and transformations enabled for vectorization.	`-no-vec`	`/Qvec[-]` (i32, i64em)
`-[no-]vec-guard-write` (i32, i64em)	Tells the compiler to perform a conditional check in a vectorized loop.	`-no-vec-guard-write`	`/Qvec-guard-write[-]` (i32, i64em)
`-vec-report`[*n*] (i32, i64em)	Controls the diagnostic information reported by the vectorizer.	`-vec-report1`	`/Qvec-report`[*n*] (i32, i64em)
`-vec-threshold`[*n*] (i32, i64em)	Sets a threshold for the vectorization of loops.	`-vec-threshold100`	`/Qvec-thresh-old`[[:]*n*] (i32, i64em)

Option	Description	Default	Equivalent Option on Windows* OS
-[no]vms	Causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).	-novms	/[no]vms
-w	Disables all warning messages; same as specifying option -warn noneor -warn nogeneral.	OFF	/w
-W*n*	Disables (*n*=0) or enables (*n*=1) all warning messages.	-W1	/W*n*
-Wa,o1[,o2,...]	Passes options (o1,o2, and so forth) to the assembler for processing.	OFF	None
-warn [*keyword*]	Specifies diagnostic messages to be issued by the compiler.	keywords: alignments nodeclarations noerrors general noignore_loc nointerfaces nostderrors notruncated_source nouncalled nounused usage	/warn[:*keyword*]

Option	Description	Default	Equivalent Option on Windows* OS
-[no]watch [*keyword*]	Tells the compiler to display certain information to the console output window.	-nowatch	/[no]watch[:*keyword*]
-WB	Turns a compile-time bounds check error into a warning.	OFF	/WB
-what	Tells the compiler to display its detailed version string.	OFF	/what
-Winline	Enables diagnostics about what is inlined and what is not inlined.	OFF	None
-Wl,option1 [,option2,...]	Passes options (o1, o2, and so forth) to the linker for processing.	OFF	None
-Wp,option1 [,option2,...]	Passes options (o1, o2, and so forth) to the preprocessor.	OFF	None
-x*p* (i32, i64em)	Tells the compiler to generate optimized code specialized for the Intel processor that executes your program.	varies; see the option description	/Qx*p* (i32, i64em)

Option	Description	Default	Equivalent Option on Windows* OS
-X	Removes standard directories from the include file search path.	OFF	/X
-Xlinker *option*	Passes a linker option directly to the linker	OFF	None
-y	Specifies that the source file should be checked only for correct syntax; same as the -syntax-only option.	OFF	/Zs
-[no]zero	Initializes to zero all local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are saved but not yet initialized.	-nozero	/Qzero[-]
-Zp[*n*]	Aligns fields of records and components of derived types on the smaller of the size boundary specified or the boundary that will naturally align them.	-Zp16	/Zp[*n*]

This topic lists related options that can be used under certain conditions.

Linking Tools and Options

This topic describes how to use the Intel® linking tools, `xild` (Linux* OS and Mac OS* X) or `xilink` (Windows* OS).

The Intel linking tools behave differently on different platforms. The following sections summarizes the primary differences between the linking behaviors.

Linux OS and Mac OS X Linking Behavior Summary

The linking tool invokes the compiler to perform IPO if objects containing IR (intermediate representation) are found. (These are mock objects.) It invokes GNU `ld` to link the application.

The command-line syntax for `xild` is the same as that of the GNU linker:

```
xild [<options>] <normal command-line>
```

where:

- `[<options>]`: (optional) one or more options supported only by `xild`.
- `<normal command-line>`: linker command line containing a set of valid arguments for `ld`.

To create `app` using IPO, use the option `-o`*`file`* as shown in the following example:

```
xild -qipo_fas -oapp a.o b.o c.o
```

The linking tool calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker then calls `ld` to link the object files that are specified in the new list and produce the application with the name specified by the `-o` option. The linker supports the `-ipo`, `-ipo`*`N`*, and `-ipo-separate` options.

Windows OS Linking Behavior Summary

The linking tool invokes the Intel compiler to perform multi-file IPO if objects containing IR (intermediate representation) is found. These are mock objects. It invokes Microsoft* `link.exe` to link the application.

Windows OS Linking Behavior Summary

The command-line syntax for the Intel® linker is the same as that of the Microsoft linker:
`xilink [<options>] <normal command-line>`
where:
• `[<options>]`: (optional) one or more options supported only by `xilink`.
• `<normal command-line>`: linker command line containing a set of valid arguments for the Microsoft linker.
To place the multifile IPO executable in `ipo_file.exe`, use the linker option `/out:`*`file`*; for example:
`xilink -qipo_fas /out:ipo_file.exe a.obj b.obj c.obj`
The linker calls the compiler to perform IPO for objects containing `IR` and creates a new list of object(s) to be linked. The linker calls Microsoft `link.exe` to link the object files that are specified in the new list and produce the application with the name specified by the `/out:`*`file`* linker option.

Using the Linking Tools

You must use the Intel linking tools to link your application if the following conditions apply:

- Your source files were compiled with multifile IPO enabled. Multi-file IPO is enabled by specifying the `-ipo` (Linux OS and Mac OS X) or `/Qipo` (Windows OS) command-line option.
- You normally would invoke either the GNU linker (`ld`) or the Microsoft linker (`link.exe`) to link your application.

The following table lists the available, case-insensitive options supported by the Intel linking tools and briefly describes the behavior of each option:

Linking Tools Option	Description
`-qhelp`	Lists the available linking tool options. Same as passing no option.
`-qnoipo`	Disables multi-file IPO compilation.

Linking Tools Option	Description
-qipo_fa*[{file|dir/}]*	Produces assembly listing for the multi-file IPO compilation. You may specify an optional name for the listing file, or a directory (with the backslash) in which to place the file. The default listing name is depends on the platform: • Linux OS and Mac OS X: ipo_out.s • Windows OS: ipo_out.asm If the Intel linking tool invocation results in multi-object compilation, either because the application is big or because the user explicitly instructed the compiler to generate multiple objects, the first .s (Linux OS and Mac OS X) or .asm (Windows OS) file takes its name from the -qipo_fa option. The compiler derives the names of subsequent .s (Linux OS and Mac OS X) or .asm (Windows OS) files by appending an incrementing number to the name, for example, foo.asm and foo1.asm for ipo_fafoo.asm. The same is true for the -qipo_fo option (listed below).
-qipo_fo*[{file|dir/}]*	Produces object file for the multi-file IPO compilation. You may specify an optional name for the object file, or a directory (with the backslash) in which to place the file. The default object file name is depends on the platform: • Linux OS and Mac OS X: ipo_out.o • Windows OS: ipo_out.obj
-qipo_fas	Add source lines to assembly listing.

Linking Tools Option	Description
-qipo_fac	Adds code bytes to the assembly listing.
-qipo_facs	Add code bytes and source lines to assembly listing.
-quseenv	Disables override of existing PATH, LIB, and INCLUDE variables.
-lib	Invokes librarian instead of linker.
-libtool	Mac OS X: Invokes libtool to create a library instead of ld.
-qv	Displays version information.

Fortran Preprocessor Options

The Fortran preprocessor (fpp) may be invoked automatically or by specifying option fpp.

The following options are available if fpp is in effect.

fpp Option	Description
-B	Specifies that C++-style comments should not be recognized.
-C	Specifies that C-style comments should not be recognized. This is the same as specifying -c_com=no.

fpp Option	Description
`-c_com={yes|no}`	Determines whether C-style comments are recognized. If you specify `-c_com=no` or `-C`, C-style comments are not recognized. By default, C-style comments are recognized; that is, `-c_com=yes`.
`-Dname`	Defines the preprocessor variable name as 1 (one). This is the same as if a `-Dname=1` option appeared on the fpp command line, or as if a `#define name 1` line appeared in the source file processed by fpp.
`-Dname=def`	Defines name as if by a #define directive. This is the same as if a `#define name def` line appeared in the source file processed by fpp. The `-D` option has lower precedence than the `-U` option. That is, if the same name is used in both a `-U` option and a `-D` option, the name will be undefined regardless of the order of the options.
`-e`	Tells the compiler to accept extended source lines. For fixed format, lines can contain up to 132 characters. For free format, lines can contain up to 32768 characters.
`-e80`	Tells the compiler to accept extended source lines. For fixed format, lines can contain up to 80 characters.
`-fixed`	Tells the compiler to assume fixed format in the source file.

fpp Option	Description
-free	Tells the compiler to assume free format in the source file.

-f_com={yes|no}	Determines whether Fortran-style end-of-line comments are recognized or ignored by fpp. If you specify -f_com=no, Fortran style end-of-line comments are processed as part of the preprocessor directive. By default, Fortran style end-of-line comments are recognized by fpp on preprocessor lines and are ignored by fpp; that is, -f_com=yes. For example:
	`#define max 100 ! max number`
	`do i = 1, max + 1`
	If you specify -f_com=yes, fpp will output
	`do i = 1, 100 + 1`
	If you specify -f_com=no, fpp will output
	`do i = 1, 100 ! max number + 1`

-help	Displays information about fpp options.
-I<dir>	Inserts directory <dir> into the search path for #include files with names not beginning with "/". The <dir> is inserted ahead of the standard list of "include" directories so that #include files with names enclosed in double-quotes (") are searched for first in the directory of the file with the #include line, then in directories named with -I options, and lastly, in directories from the standard list. For #include files with names enclosed in angle-brackets (<>), the directory of the file with the #include line is not searched.
-m	Expands macros everywhere. This is the same as -macro=yes.

fpp Option	Description
macro={yes|no_com|no}	Determines the bahavior of macro expansion. If you specify -macro=no_com, macro expansion is turned off in comments. If you specify -macro=no, no macro expansion occurs anywhere. By default, macros are expanded everywhere; that is, -macro=yes.
-noB	Specifies that C++-style comments should be recognized.
-noC	Specifies that C-style comments should be recognized. This is the same as -c_com=yes.
-noJ	Specifies that F90-style comments should be recognized in a #define line. This is the same as -f_com=no.
-no-fort-cont	Specifies that IDL style format should be recognized. This option is only for the IDE. Note that macro arguments in IDL may have a C-like continuation character "\" which is different from the Fortran continuation character "&". Fpp should recognize the C-like continuation character and process some other non-Fortran tokens so that the IDL processor can recognize them.
-P	Tells the compiler that line numbering directives should not be added to the output file. This line-numbering directive appears as #line-number file-name
-Uname	Removes any initial definition of name, where name is an fpp variable that is predefined on a particular preprocessor. Here is a partial list of symbols that may be predefined, depending upon the architecture of the system:

fpp Option	Description
	Operating System: __APPLE__, __unix, and __linux Hardware: __i386, __ia64, __x86_64
-undef	Removes initial definitions for all predefined symbols.
-V	Displays the fpp version number.
-w[0]	Prevents warnings from being output. By default, warnings are output to stderr.
-Xu	Converts uppercase letters to lowercase, except within character-string constants. The default is to leave the case as is.
-Xw	Tells the compiler that in fixed-format source files, the blank or space symbol " " is insignificant. By default, the space symbol is the delimiter of tokens for this format.
-Y<dir>	Adds directory <dir> to the end of the system include paths.

For details on how to specify these options on the compiler command line, see fpp, Qfpp.

Floating-Point Environment

The floating-point (FP) environment is a collection of registers that control the behavior of FP machine instructions and indicate the current FP status. The floating-point environment may include rounding mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.

Intel(R) Fortran Optimizing Applications

23

Overview: Optimizing Applications

Optimizing Applications explains how to use the Intel® Fortran Compiler to help improve application performance.

How you use the information presented in this document depends on what you are trying to accomplish. You can start with the following topics:

- Optimizing with the Intel Compiler
- Optimizing for Performance
- Overview of Parallelism Methods
- Quick Reference Lists
- Other Resources
- Performance Analysis

Where applicable this document explains how compiler options and optimization methods differ on IA-32, Intel® 64, and IA-64 architectures on Linux* operating systems (OS), Intel®-based systems running Mac OS* X, and Windows* operating systems.

While the compiler supports Integrated Development Environments (IDE) on several different operating systems, the concepts and examples included here illustrate using the compiler from the command line.

In most cases, the compiler features and options supported for IA-32 or Intel® 64 architectures on Linux OS are also supported on Intel-based systems running Mac OS X. For more detailed information about support for specific operating systems, refer to the appropriate option in Compiler Options.

Optimizing with the Intel® Compiler

The Intel compiler supports a variety of options and features that allow optimization opportunities; however, in most cases you will benefit by applying optimization strategies in the order listed below.

Use Automatic Optimizations

Use the automatic optimization options, like `-O1`, `-O2`, `-O3`, or `-fast` (Linux* and Mac OS* X) and `/O1`, `/O2`, `/O3`, or `/fast` (Windows*) to determine what works best for your application. Use these options and measure the resulting performance after each compilation.

NOTE. The optimizer that integrates parallelization (IA-32, Intel® 64, and IA-64 architectures) and vectorization (IA-32 and Intel® 64 architectures) has been redesigned to provide performance improvements when specifying the `-O2` or `-O3` (Linux and Mac OS X) and `/O2` or `/O3` (Windows) options.

You might find specific options to work better on a particular architecture:

- IA-32 and Intel® 64 architectures: start with `-O2` (Linux and Mac OS X) or `/O2` (Windows).
- IA-64 architecture: start with `-O3` (Linux and Mac OS X) or `/O3` (Windows).

If you plan to run your application on specific architectures, experiment with combining the automatic optimizations with compiler options that specifically target processors.

You can combine the `-x` and `-ax` (Linux* and Mac OS* X) or `/Qx` and `/Qax` (Windows*) options to generate both code that is optimized for specific Intel processors and generic code that will run on most processors based on IA-32 and Intel® 64 architectures. See the following topics for more information about targeting processors:

- Targeting IA-32 and Intel® 64 Architecture Processors Automatically
- Targeting Multiple IA-32 and Intel 64 Architecture Processors Automatically for Run-time Performance
- Targeting Itanium® Processors Automatically

Attempt to combine the automatic optimizations with the processor-specific options before applying other optimizations techniques.

Use IPO and PGO

Experiment with Interprocedural Optimization (IPO) and Profile-guided Optimization (PGO). Measure performance after applying the optimizations to determine whether the application performance improved.

Use a top-down, iterative method for identifying and resolving performance-hindering code using performance monitoring tools, like the compiler reports.

Use Parallelism

If you are planning to run the application on multi-core or multi-processor systems, start the parallelism process by using the parallelism options or OpenMP* options.

Compiling for Older Processors

Use automatic optimization options and other processor-independent compiler options to generate optimized code that do not take advantage of advances in processor design or extension support. Use the `-x` (Linux* and Mac OS* X) or `/Qx` (Windows*) option to generate processor dispatch for older processors.

Optimizing for Performance

Overview of Parallelism Method

The three major features of parallel programming supported by the Intel® compiler include:

- OpenMP*
- Auto-parallelization

- Auto-vectorization

Each of these features contributes to application performance depending on the number of processors, target architecture (IA-32, Intel® 64, and IA-64 architectures), and the nature of the application. These features of parallel programming can be combined to contribute to application performance.

Parallelism defined with the OpenMP* API is based on thread-level and task-level parallelism. Parallelism defined with auto-parallelization techniques is based on thread-level parallelism (TLP). Parallelism defined with auto-vectorization techniques is based on instruction-level parallelism (ILP).

Parallel programming can be *explicit*, that is, defined by a programmer using the OpenMP* API and associate options. Parallel programming can also be *implicit*, that is, detected automatically by the compiler. Implicit parallelism implements auto-parallelization of outer-most loops and auto-vectorization of innermost loops (or both).

To enhance the compilation of the code with auto-vectorization, users can also add vectorizer directives to their program.

NOTE. Software pipelining (SWP), a technique closely related to auto-vectorization, is available on systems based on IA-64 architecture.

The following table summarizes the different ways in which parallelism can be exploited with the Intel® Compiler.

Intel provides performance libraries that contain highly optimized, extensively threaded routines, including the Intel® Math Kernel Library (Intel® MKL).

In addition to these major features supported by the Intel compiler, certain operating systems support application program interface (API) function calls that provide explicit threading controls. For example, Windows* operating systems support API calls such as `CreateThread`, and multiple operating systems support POSIX* threading APIs.

Parallelism Method	Supported On
Implicit (parallelism generated by the compiler and by user-supplied hints)	
Auto-parallelization (Thread-Level Parallelism)	• IA-32 architecture, Intel® 64 architecture, IA-64 architecture based multi-processor systems, and multi-core processors • Hyper-Threading Technology-enabled systems

Parallelism Method	Supported On
Auto-vectorization (Instruction-Level Parallelism)	• Pentium®, Pentium with MMX™ Technology, Pentium II, Pentium III, Pentium 4 processors, Intel® Core™ processor, and Intel® Core™ 2 processor.
Explicit (parallelism programmed by the user)	
OpenMP* (Thread-Level and Task-Level Parallelism)	• IA-32 architecture, Intel® 64 architecture, IA-64 architecture-based multiprocessor systems, and multi-core processors • Hyper-Threading Technology-enabled systems

Threading Resources

For general information about threading an existing serial application or design considerations for creating new threaded applications, see Other Resources and the web site http://go-parallel.com.

Quick Reference Lists

There are several quick reference guides in this document. Use these quick reference guides to quickly familiarize yourself with the compiler options or features available for specific optimizations.

Other Resources

Understanding the capabilities of the specific processors and the underlying architecture on which your application will run is key to optimization. Intel distributes many hardware and software development resources that can help better understand how to optimize application source code for specific architectures.

Processor Information

You can find detailed information about processor numbers, capabilities, and technical specifications, along with documentation, from the following web sites:

- *Intel® Processor Spec Finder* (http://processorfinder.intel.com/)
- *Intel® Processor Numbers* (http://www.intel.com/products/processor_number/)
- *Intel® Processor Identification Utility* (http://www.intel.com/support/processors/tools/piu/)

Architecture Information

The architecture manuals provide specific details about the basic architecture, supported instruction sets, programming guidelines for specific operating systems, and performance monitoring.

The optimization manuals provide insight for developing high-performance applications for Intel® architectures.

Evaluating Performance 24

Performance Analysis

The high-level information presented in this section discusses methods, tools, and compiler options used for analyzing runtime performance-related problems and increasing application performance.

The topics in this section discuss performance issues and methods from a general point of view, focusing primarily on general performance enhancements. The information in this section is separated in the following topics:

- Using a Performance Enhancement Methodology
- Performance Enhancement Strategies
- Using Intel Performance Analysis Tools

In most cases, other sections and topics in this document contain detailed information about the options, concepts, and strategies mentioned in this section.

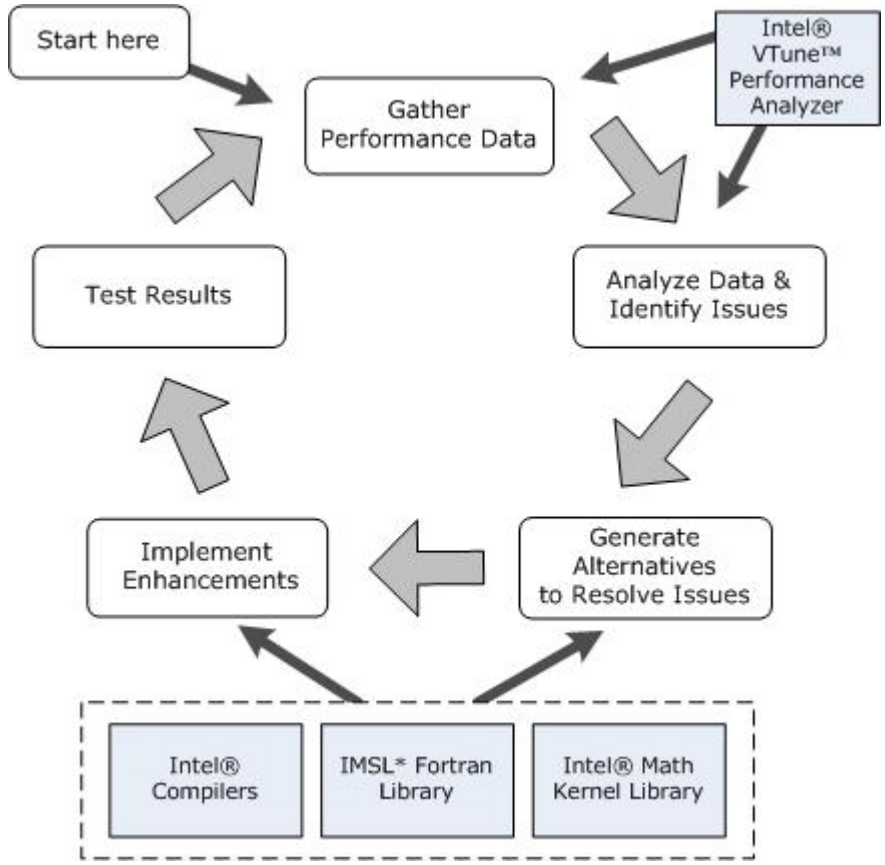
This section also contains information about using the compiler-supporting reports and diagnostics.

Using a Performance Enhancement Methodology

The recommended performance enhancement method for optimizing applications consists of several phases. When attempting to identify performance issues, move through the following general phases in the order presented:

- Gather performance data
- Analyze the data
- Generate alternatives
- Implement enhancements
- Test the results

The following figure shows the methodology phases and their relationships, along with some recommended tools to use in each appropriate phase.



The methodology can be summarized by the following statements:

- Make small changes and measure often.
- If you approach a point of diminishing return and can find no other performance issues, stop optimizing.

Gather performance data

Use tools to measure where performance bottlenecks occur; do not waste time guessing. Using the right tools for analysis provides an objective data set and baseline criteria to measure implementation changes and improvements introduced in the other stages.

See Using Intel Performance Analysis Tool and Libraries for more information about some tools you can use to gather performance data.

Analyze the data

Determine if the data meet your expectations about the application performance. If not, choose one performance problem at a time for special interest. Limiting the scope of the corrections is critical in effective optimization.

In most cases, you will get the best results by resolving hotspots first. Since hotspots are often responsible for excessive activity or delay, concentrating on these areas tends to resolve or uncover other performance problems that would otherwise be undetectable.

Generate alternatives

As in the analysis phase, limit the focus of the work. Concentrate on generating alternatives for the one problem area you are addressing. Identify and use tools and strategies to help resolve the issues. For example, you can use compiler optimizations, use Intel® Performance Library routines, or use some other optimization (like improved memory access patterns, reducing or eliminating division or other floating-point operations, rewriting the code to include intrinsics or assembly code, or other strategies).

See Performance Enhancement Strategies for suggestions.

While optimizing for the compiler and source levels, consider using the following strategies in the order presented:

1. Use available supported compiler options. This is the most portable, least intrusive optimization strategy.
2. Use compiler directives embedded in the source. This strategy is not overly intrusive since the method involves including a single line in code, which can be ignored (optionally) by the compiler.
3. Attempt manual optimizations.

Implement enhancements

As with the previous phases, limit the focus of the implementation. Make small, incremental changes. Trying to address too many issues at once can defeat the purpose and reduce your ability to test the effectiveness of your enhancements.

The easiest enhancements will probably involve enabling common compiler optimizations for easy gains. For applications that can benefit from the libraries, consider implementing Intel® Performance Library routines that may require some interface coding.

Test the results

If you have limited the scope of the analysis and implementation, you should see measurable differences in performance in this phase. Have a target performance level in mind so you know when you have reached an acceptable gain in performance.

Use a consistent, reliable test that reports a quantifiable item, like seconds elapsed, frames per second, and so forth, to determine if the implementation changes have actually helped performance.

If you think you can make significant improvement gains or you still have other performance issues to address, repeat the phases beginning with the first one: gather performance data.

Intel® Performance Analysis Tools and Libraries

Intel Corporation offers a variety of performance analysis tools and libraries that can help you optimize your application performance.

Performance Analysis Tools

These performance tools can help you analyze your application, find problem areas, and develop efficient programs. In some cases, these tools are critical to the optimization process.

Tool	Operating System	Description
Intel® Threading Analysis Tools	Linux, Windows	Intel® Threading Analysis Tools consist of the Intel® Thread Checker and the Intel® Thread Profiler. The Intel® Thread Checker can help identify shared and private variable conflicts, and can isolate threading bugs to the source code line where the bug occurs.

Tool	Operating System	Description
		The Intel® Thread Profiler can show the critical path of an application as it moves from thread to thread, and identify synchronization issues and excessive blocking time that cause delays for Win32*, POSIX* threaded, and OpenMP* code.

Performance Libraries

These performance libraries can decrease development time and help to increase application performance.

Library	Operating System	Description
Intel® Math Kernel Library	Linux, Mac OS X, Windows	Intel® Math Kernel Library offers highly optimized, thread-safe math routines for science, engineering, and financial applications that require maximum performance.

Performance Enhancement Strategies

Improving performance starts with identifying the characteristics of the application you are attempting to optimize. The following table lists some common application characteristics, indicates the overall potential performance impact you can expect, and provides suggested solutions to try. These strategies have been found to be helpful in many cases; experimentation is key with these strategies.

In the context of this discussion, view the potential impact categories as an indication of the possible performance increases that might be achieved when using the suggested strategy. It is possible that application or code design issues will prohibit achieving the indicated increases; however, the listed impacts are generally true. The impact categories are defined in terms of the following performance increases, when compared to the initially tested performance:

- Significant: more than 50%
- High: up to 50%
- Medium: up to 25%
- Low: up to 10%

The following table is ordered by application characteristics and then by strategy with the most significant potential impact.

Application Characteristics	Impact	Suggested Strategies
Technnical Applications		
Technical applications with loopy code	High	Technical applications are those programs that have some subset of functions that consume a majority of total CPU cycles in loop nests. Target loop nests using `-O3` (Linux* and Mac OS* X) or `/O3` (Windows*) to enable more aggressive loop transformations and prefetching. Use High-Level Optimization (HLO) reporting to determine which HLO optimizations the compiler elected to apply. See High-Level Optimization Report.
(same as above) IA-64 architecture only	High	For `-O2` and `-O3` (Linux) or `/O2` and `/O3` (Windows), use the swp report to determine if Software Pipelining occurred on key loops, and if not, why not. You might be able to change the code to allow software pipelining under the following conditions:

Application Characteristics	Impact	Suggested Strategies
		• If recurrences are listed in the report that you suspect do not exist, eliminate aliasing problems , or use `IVDEP` directive on the loop. • If the loop is too large or runs out of registers, you might be able to distribute the loop into smaller segments; distribute the loop manually or by using the `distribute` directive. • If the compiler determines the Global Acyclic Scheduler can produce better results but you think the loop should still be pipelined, use the `SWP` directive on the loop.
(same as above) IA-32 and Intel® 64 architectures only	High	See Vectorization Overview and the remaining topics in the Auto-Vectorization section for applicable options. See Vectorization Report for specific details about when you can change code.
(same as above)	Medium	Use PGO profile to guide other optimizations. See Profile-guided Optimizations Overview.
Applications with many denormalized floating-point value operations	Significant	Experiment with `-fp-model fast=2` (Linux and Mac OS X) or `/fp:fast=2` or `-ftz` (Linux and Mac OS X) or `/Qftz` (Windows). The

Application Characteristics	Impact	Suggested Strategies
		resulting performance increases can adversely affect floating-point calculation precision and reproducibility. See Floating-point Operations for more information about using the floating point options supported in the compiler.
Sparse matrix applications	Medium	See the suggested strategy for memory pointer disambiguation (below). Use `prefetch` directive or prefetch intrinsics. Experiment with different prefetching schemes on indirect arrays. See HLO Overview or Data Prefetching starting places for using prefetching.
Server application with branch-centric code and a fairly flat profile	Medium	Flat profile applications are those applications where no single module seems to consume CPU cycles inordinately. Use PGO to communicate typical hot paths and functions to the compiler, so the Intel® compiler can arrange code in the optimal manner. Use PGO on as much of the application as is feasible. See Profile-guided Optimizations Overview.

Application Characteristics	Impact	Suggested Strategies
Database engines	Medium	Use `-O1` (Linux and Mac OS X) or `/O1` (Windows) and PGO to optimize the application code.
Other Application Types		
Applications with many small functions that are called from multiple locations	Low	Use `-ip` (Linux and Mac OS X) or `/Qip` (Windows) to enable inter-procedural inlining within a single source module. Streamlines code execution for simple functions by duplicating the code within the code block that originally called the function. This will increase application size. As a general rule, do not inline large, complicated functions. See Interprocedural Optimizations Overview.
(same as above)	Low	Use `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows) to enable inter-procedural inlining both within and between multiple source modules. You might experience an additional increase over using `-ip` (Linux and Mac OS X) or `/Qip` (Windows). Using this option will increase link time due to the extended program flow analysis that occurs.

Application Characteristics	Impact	Suggested Strategies
		Use Interprocedural Optimization (IPO) to attempt to perform whole program analysis, which can help memory pointer disambiguation.

Apart from application-specific suggestions listed above, there are many application-, OS/Library-, and hardware-specific recommendations that can improve performance as suggested in the following tables:

Application-specific Recommendations

Application Area	Impact	Suggested Strategies
Cache Blocking	High	Use `-O3` (Linux and Mac OS X) or `/O3` (Windows) to enable automatic cache blocking; use the HLO report to determine if the compiler enabled cache blocking automatically. If not consider manual cache blocking. See Cache Blocking.
Compiler directives for better alias analysis	Medium	Ignore vector dependencies. Use `IVDEP` and other directives to increase application speed. See Vectorization Support.
Math functions	Low	Use float intrinsics for single precision data type, for example, `sqrtf()` not `sqrt()`. Call Math Kernel Library (MKL) instead of user code. Call F90 intrinsics instead of user code (to enable optimizations).

Library/OS Recommendations

Area	Impact	Description
Symbol preemption	Low	Linux has a less performance-friendly symbol preemption model than Windows. Linux uses full preemption, and Windows uses no preemption. Use `-fminshared -fvisibility=protected`. See Symbol Visibility Attribute Options.
Memory allocation	Low	Using third-party memory management libraries can help improve performance for applications that require extensive memory allocation.

Hardware/System Recommendations

Component	Impact	Description
Disk	Medium	Consider using more advanced hard drive storage strategies. For example, consider using SCSI instead of IDE. Consider using the appropriate RAID level. Consider increasing the number hard drives in your system.
Memory	Low	You can experience performance gains by distributing memory in a system. For example, if you have four open memory slots and only two slots are

Component	Impact	Description
		populated, populating the other two slots with memory will increase performance.
Processor		For many applications, performance scales is directly affected by processor speed, the number of processors, processor core type, and cache size.

Using Compiler Reports

Compiler Reports Overview

The Intel® compiler provides several reports that can help identify performance issues.

Some of these compiler reports are architecture-specific, most are more general. Start with the general reports that are common to all platforms (operating system/architecture), then use the reports unique to an architecture.

- Generating reports
- Interprocedural Optimizations (IPO) report
- Profile-Guided Optimizations (PGO) report
- High-level Optimizations (HLO) report
- Software-pipelining (SWP) report (IA-64 architecture only)
- Vectorization report
- Parallelism report
- OpenMP* report

Compiler Reports Quick Reference

The Intel® compiler provides the following options to generate and manage optimization reports:

Linux* and Mac OS* X	Windows*	Description
-opt-report or -opt-report N	/Qopt-report or /Qopt-report:N	Generates optimization report, with different levels of detail, directed to stderr. Valid values for N are 0 through 3. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail.
-opt-report-phase	/Qopt-report-phase	Specifies the optimization phase to use when generating reports. If you do not specify a phase the compiler defaults to all, which can adversely affect compile times. See Generating Reports for more information about the supported phases.
-opt-report-file	/Qopt-report-file	Generates an optimization report and directs the report output to the specified file name. If the file is not in the local directory, supply the full path to the output file. This option overrides the opt-report option.
-opt-report-routine	/Qopt-report-routine	Generates reports from all routines with names containing a string as part of their name; pass the string as an argument to this option. If not specified, the compiler will generate reports on all routines.

Linux* and Mac OS* X	Windows*	Description
-diag-<type>	/Qdiag-<type>	This option is not a compiler reports option; however, it controls the diagnostic message levels generated by the compiler, and it offers a means to provide useful information without needing to generate reports. <*type*> is a placeholder for several different values or lists.

This quick reference does not list the options for the vectorization, parallelism, or OpenMP* reports.

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

If you use interprocedural optimization (IPO) options, you can request compiler reports when using the xi* tools , as described in Requesting Compiler Reports with the xi* Tools.

Generating Reports

Use the options listed in this topic to generate reports on the following optimizers.

- Interprocedural Optimization (IPO)
- Profile-guided Optimization (PGO)
- High Performance Optimizer (HPO)
- High-level Optimization (HLO)
- Intermediate Language Scalar Optimization (ILO)
- Software Pipelining (SWP)

Specify an optimizer phase by passing the `phase` argument to the `-opt-report-phase` (Linux* and Mac OS* X) or `/Qopt-report-phase` (Windows*) option.

Optimizer Phase	Supported Optimizer
`pgo`	Profile-guided Optimizer
`ipo`	Interprocedural Optimizer
`ilo`	Intermediate Language Scalar Optimizer

Optimizer Phase	Supported Optimizer
hpo	High Performance Optimizer
hlo	High-level Optimizer
ecg	Itanium® Compiler Code Generator Mac OS X: This phase is not supported.
ecg_swp	The software pipelining component of the Code Generator phase (Windows and Linux systems using IA-64 architecture only)
all	All optimizers supported on the architecture. This is not recommended; the resulting output can be too extensive to be useful. Experiment with targeted phase reports first.

Reports Available by Architecture and Option

IA-32, Intel® 64, and IA-64 architectures:

- ilo and pgo
- hpo and hlo: For IA-32 architecture, supported with -x (Linux and Mac OS X) or /Qx (Windows) option.

  For Intel® 64 architecture, supported with -O2 (Linux and Mac OS X) or /O2 (Windows) option. For IA-32 and Intel® 64 architectures, a subset of these optimizations are enabled at default optimization level (O2). For IA-64 architecture, supported with -O3 (Linux and Mac OS X) or /O3 (Windows) option.
- ipo: Interprocedural optimization is enabled for -O2 (Linux and Mac OS X) or /O2 (Windows) option or above.
- all: All of the above.

IA-64 architecture only:

- ecg

Running the Reports

Use syntax similar to the following to run the compiler reports.

Operating System	Sample Syntax
Linux and Mac OS X	ifort -c -opt-report 2 -opt-report-phase=all sample.f90
Windows	ifort /c /Qopt-report:2 /Qopt-report-phase:all sample.f90

The sample command instructs the compiler to generate a report and send the results to `stderr` and specifies the reports should include information about all available optimizers. In most cases, specifying `all` as the phase will generate too much information to be useful.

If you want to capture the report in an output file instead of sending it to `stderr`, specify `-opt-report-file` (Linux and Mac OS X) or `/Qopt-report-file` (Windows) and indicate an output file name. If you do not want the compiler to invoke the linker, specify `-c` (Linux and Mac OS X) or `/c` (Windows) >as shown in the sample syntax above; by specifying the option you instruct the compiler to stop after generating object code and reporting the results.

See Compiler Reports Quick Reference for information about how to use the report related options.

When you specify a phase name, as shown above, the compiler generates all reports from that optimizer. The option can be used multiple times on the same command line to generate reports for multiple optimizers. For example, for if you specified `-opt-report-phase ipo -opt-report-phase hlo` (Linux and Mac OS X) or `/Qopt-report-phase ipo /Qopt-report-phase hlo` (Windows) the compiler generates reports from the interprocedural optimizer and the high-level optimizer code generator.

You do not need to fully specify an optimizer name in the command; in many cases, the first few characters should suffice to generate reports; however, all optimization reports that have a matching prefix are generated.

Each of the optimizer logical names supports many specific, targeted optimizations within them. Each of the targeted optimizations have the prefix of the optimizer name. Enter `-opt-report-help` (Linux and Mac OS X) or `/Qopt-report-help` (Windows) to list the names of optimizers that are supported. The following table lists some examples:

Optimizer	Description
`ipo_inl`	Interprocedural Optimizer, inline expansion of functions
`ipo_cp`	Interprocedural Optimizer, constant propagation
`hlo_unroll`	High-level Optimizer, loop unrolling

Optimizer	Description
hlo_prefetch	High-level Optimizer, prefetching

Viewing the Optimization Reports Graphically (Linux)

To generate the graphical report display, you must compile the application using the following optimization reports options, at a minimum: `-opt-report-phase` and `-opt-report-file`.

As with the text-based reports, the graphical report information can be generated on all architectures.

Interprocedural Optimizations (IPO) Report

The IPO report provides information on the functions that have been inlined and can help to identify the problem loops. The report can help to identify how and where the compiler applied IPO to the source files.

The following command examples demonstrate how to run the IPO reports with the minimum output.

Operating System	Syntax Examples
Linux* and Mac OS* X	`ifort -opt-report 1 -opt-report-phase=ipo a.f90 b.f90`
Windows*	`ifort /Qopt-report:1 /Qopt-report-phase:ipo a.f90 b.f90`

where `-opt-report` (Linux and Mac OS X) or `/Qopt-report` (Windows) invokes the report generator, and `-opt-report-phase=ipo` (Linux and Mac OS X) or `/Qopt-report-phase:ipo` (Windows) indicates the phase (`ipo`) to report.

You can use `-opt-report-file` (Linux and Mac OS X) or `/Qopt-report-file` (Windows) to specify an output file to capture the report results. Specifying a file to capture the results can help to reduce the time you spend analyzing the results and can provide a baseline for future testing.

Reading the Output

The IPO report details information in two general sections: whole program analysis and inlining. By default, the report generates a medium level of detail. You can specify an output file to capture the report results. Running maximum IPO report results can be very extensive and technical; specifying a file to capture the results can help to reduce analysis time. The following sample report illustrates the general layout.

Sample IPO Report

```
<;-1:-1;IPO;;0>
WHOLE PROGRAM (SAFE) [EITHER METHOD]: TRUE
WHOLE PROGRAM (SEEN) [TABLE METHOD]: TRUE
WHOLE PROGRAM (READ) [OBJECT READER METHOD]: TRUE
INLINING OPTION VALUES:
  -inline-factor: 100
  -inline-min-size: 20
  -inline-max-size: 230
  -inline-max-total-size: 2000
  -inline-max-per-routine: disabled
  -inline-max-per-compile: disabled
<ipo_sample_main.f90;29:37;IPO INLINING;MAIN__;0>
INLINING REPORT: (MAIN__) [1/4=25.0%]
  -> for_write_seq_lis(EXTERN)
  -> INLINE: mysum_(5) (isz = 23) (sz = 30 (13+17))
...
<ipo_sample_init.f90;32:40;IPO CONSTANT PROPAGATION;init_;0>
  CONSTANT PROPAGATION:  VARS(1)
...
```

The following table summarizes the common report elements and provides a general description to help interpret the results.

Report Element	Description
WHOLE PROGRAM (SAFE) [EITHER METHOD]:	TRUE or FALSE. • TRUE: The compiler determined, using one or both of the whole program analysis models, that the whole program was present during compilation. • FALSE: The compiler determined the whole program was not present during compilation. The compiler could not apply whole program IPO. See Inteprocedural Optimizations (IPO) Overview for more information on the whole program analysis models.
WHOLE PROGRAM (SEEN) [TABLE METHOD]:	TRUE or FALSE. • TRUE: The compiler resolved all references, either within the application code or in the standard table for the functions within the compiler. • FALSE: The compiler could not resolve all references. One or more functions references could not be found either in the user code or standard functions table.
WHOLE PROGRAM (READ) [OBJECT READER METHOD]:	TRUE or FALSE. • TRUE: The compiler determined that all conditions were met for linking at a level equivalent to the -O0 (Linux and Mac OS X) or /Od (Windows) option. • FALSE: The compiler could not resolve one or more references. The linking step failed.

Report Element	Description
INLINING OPTION VALUES:	Displays the compilation values used for the following developer-directed inline expansion options: • inline-factor • inline-min-size • inline-max-size • inline-max-total-size • inline-max-per-routine • inline-max-per-compile If you specify the one or more of the appropriate options, the report lists the values you specified; if you do not specify an option and value the compiler uses the defaults values for the listed options, and the compiler will list the default values. The values indicate the same intermediate language units listed in Compiler Options for each of these options. See Developer Directed Expansion of User Functions for more information about using these options.
INLINING REPORT:	Includes a string in the format of the following (<name>) [<current number>/<total number>=<percent complete>] where • <name>: the name of the function being reported on. • <current number> is the number of the function being reported on. Not every function can be inlined; gaps in the current number are common.

Report Element	Description
INLINE:	• <total number> is the total number of functions being evaluated. • <percent complete> is a simple percentage of the functions being inlined. If a function is inlined, the function line has the prefix "-> INLINE: _". The option reports displays the names of the functions. The report uses the following general syntax format: -> INLINE: _<name>(#) (isz) (sz) where • <name> : Indicates the name of the function Static functions display the function name with numbered suffix. • #: Indicates the unique integer specifying the function number. • sz: Indicates the function size before optimization. This is a rough estimate loosely representative of the number of original instructions before optimization. • isz: Indicates the function size after optimization. This value (isz) will always be less than or equal to the unoptimized size (sz). • exec_cnt: Indicates that Profile-guided Optimization was specified during compilation. Indicates the number of times the function was called from this site.

Report Element	Description
	NOTE. You can make the mangled names readable by entering the following: Linux: `echo <mangled_name> | c++filt` Windows: `undname <mangled_name>` Function calls that could not be inlined lack the `INLINE` prefix. Additionally, the compiler marks non-inlined functions using the following conventions: • `EXTERN` indicates the function contained an external function call for which the compiler was not supplied the code. • `ARGS_IN_REGS` indicates inlining did not occur. For IA-32 and Intel® 64 architectures, an alternative for functions that were not inlined is to allow the compiler to pass the function arguments in registers rather than using standard calling conventions; however, for IA-64 architecture this is the default behavior.
`DEAD STATIC FUNCTION ELIMINATION:`	Indicates the reported function is a dead static. Code does not need to be created for these functions. This behavior allows the compiler to reduce the overall code size.

Profile-guided Optimization (PGO) Report

The PGO report can help to identify can help identify where and how the compiler used profile information to optimize the source code. The PGO report is most useful when combined with the PGO compilation steps outlined in Profile an Application. Without the profiling data generated during the application profiling process the report will generally not provide useful information.

Combine the final PGO step with the reporting options by including `-prof-use` (Linux* and Mac OS* X) or `/Qprof-use` (Windows*). The following syntax examples demonstrate how to run the report using the combined options.

Operating System	Syntax Examples
Linux and Mac OS X	`ifort -prof-use -opt-report -opt-report-phase=pgo pgotools_sample.f90`
Windows	`ifort /Qprof-use /Qopt-report /Qopt-report-phase:pgo pgotools_sample.f90`

By default the PGO report generates a medium level of detail. You can use `-opt-report-file` (Linux and Mac OS X) or `/Qopt-report-file` (Windows) to specify an output file to capture the report results. Specifying a file to capture the results can help to reduce the time you spend analyzing the results and can provide a baseline for future testing.

Reading the Output

Running maximum PGO report results can produce long and detailed results. Depending on the sources being profiled, analyzing the report could be very time consuming. The following sample report illustrates typical results and element formatting for the default output.

Sample PGO Report

```
<pgotools_sample.f90;-1:-1;PGO;_DELEGATE.;0>
  DYN-VAL:  pgotools_sample.f90  _DELEGATE.
<pgotools_sample.f90;-1:-1;PGO;_ADDERMOD.;0>
  NO-DYN:   pgotools_sample.f90  _ADDERMOD.
<pgotools_sample.f90;-1:-1;PGO;_ADDERMOD_mp_MOD_ADD;0>
  DYN-VAL:  pgotools_sample.f90  _ADDERMOD_mp_MOD_ADD
<pgotools_sample.f90;-1:-1;PGO;_DELEGATE;0>
  DYN-VAL:  pgotools_sample.f90  _DELEGATE
<pgotools_sample.f90;-1:-1;PGO;_MAIN__;0>
  DYN-VAL:  pgotools_sample.f90  _MAIN__
<pgotools_sample.f90;-1:-1;PGO;_MAIN._MAIN_ADD;0>
  DYN-VAL:  pgotools_sample.f90  _MAIN._MAIN_ADD
<pgotools_sample.f90;-1:-1;PGO;;0>
      5 FUNCTIONS HAD VALID DYNAMIC PROFILES
      1 FUNCTIONS HAD NO DYNAMIC PROFILES
  FILE CURRENT  QUALITY METRIC:  91.7%
  FILE POSSIBLE QUALITY METRIC:  91.7%
  FILE QUALITY  METRIC RATIO:   100.0%
```

The following table summarizes some of the common report elements and provides a general description to help interpret the results.

Report Element	Description
String listing information about the function being reported on. The string uses the following format. <*source name*>;<*start line*>;<*end line*>;<*optimization*>; <*function name*>;<*element type*>	The compact string contains the following information: • <*source name*>: Name of the source file being examined. • <*start line*>: Indicates the starting line number for the function being examined. A value of -1 means that the report applies to the entire function. • <*end line*>: Indicates the ending line number for the function being examined. • <*optimization*>: Indicates the optimization phase; for this report the indicated phase should be PGO. • <*function name*>: Indicates the name of the function. • <*element type*>: Indicates the type of the report element; 0 indicates the element is a comment.
DYN-VAL	Indicates that valid profiling data was generated for the function indicated; the source file containing the function is also listed.
NO-DYN	Indicates that no profiling data was generated for the function indicated; the source file containing the function is also listed.
FUNCTIONS HAD VALID DYNAMIC PROFILES	Indicates the number of functions that had valid profile information.

Report Element	Description
FUNCTIONS HAD NO DYNAMIC PROFILES	Indicated the number of functions that did not have valid profile information. This element could indicate that the function was not executed during the instrumented executable runs.
FUNCTIONS HAD VALID STATIC PROFILES	Indicates the number of functions for which static profiles were generated. The most likely cause for having a non-zero number is that dynamic profiling did not happen and static profiles were generated for all of the functions.
IPO CURRENT QUALITY METRIC	Indicates the general quality, represented as a percentage value between 50% and 100%t. A value of 50% means no functions had dynamic profiles, and a value of 100% means that all functions have dynamic profiles. The larger the number the greater the percentage of functions that had dynamic profiles.
IPO POSSIBLE QUALITY METRIC	Indicates the number of possible dynamic profiles. This number represent the best possible value, as a percentage, for `Current Quality`. This number is the highest value possible and represents the ideal quality for the given data set and the instrumented executable.
IPO QUALITY METRIC RATIO	Indicates the ratio of `Possible Quality` to `Current Quality`. A value of 100% indicates that all dynamic profiles were accepted. Any value less than 100% indicates rejected profiles.

High-level Optimization (HLO) Report

High-level Optimization (HLO) performs specific optimizations based on the usefulness and applicability of each optimization. The HLO report can provide information on all relevant areas plus structure splitting and loop-carried scalar replacement, and it can provide information about interchanges not performed for the following reasons:

- Function call are inside the loop
- Imperfect loop nesting
- Reliance on data dependencies; dependencies preventing interchange are also reported.
- Original order was proper but it might have been considered inefficient to perform the interchange.

For example, the report can provide clues to why the compiler was unable to apply loop interchange to a loop nest that might have been considered a candidate for optimization. If the reported problems (bottlenecks) can be removed by changing the source code, the report suggests the possible loop interchanges.

Depending on the operating system, you must specify the following options to enable HLO and generate the reports:

- Linux* and Mac OS* X: `-x`, `-O2` or `-O3`, `-opt-report 3`, `-opt-report-phase=hlo`
- Windows*: `/Qx`, `/O2` or `/O3`, `/Qopt-report:3`, `/Qopt-report-phase:hlo`

See High-level Optimization Overview for information about enabling HLO.

The following command examples illustrate the general command needed to create HLO report with combined options.

Operating System	Example Command
Linux and Mac OS X	`ifort -c -xSSE3 -O3 -opt-report 3 -opt-report-phase=hlo sample.f90`
Windows	`ifort /c /QxSSE3 /O3 /Qopt-report:3 /Qopt-report-phase:hlo sample.f90`

You can use `-opt-report-file` (Linux and Mac OS X) or `/Qopt-report-file` (Windows) to specify an output file to capture the report results. Specifying a file to capture the results can help to reduce the time you spend analyzing the results and can provide a baseline for future testing.

Reading the report results

The report provides information using a specific format. The report format for Windows* is different from the format on Linux* and Mac OS* X. While there are some common elements in the report output, the best way to understand what kinds of advice the report can provide is to show example code and the corresponding report output.

Example 1: This example illustrates the condition where a function call is inside a loop.

Example 1

```
subroutine foo (A, B, bound)
   integer i,j,n,bound
   integer A(bound), B(bound,bound)
   n = bound
   do j = 1, n
      do i = 1, n
        B(j,i) = B(j,i) + A(j)
        call bar(A,B)
      end do
   end do
   return
end subroutine foo
```

Regardless of the operating system, the reports list optimization results on specific functions by presenting a line above there reported action. The line format and description are included below.

The following table summarizes the common report elements and provides a general description to help interpret the results.

Report Element	Description
String listing information about the function being reported on. The string uses the following format.	The compact string contains the following information: • <*source name*>: Name of the source file being examined.

Report Element	Description
<source name>;<start line>;<end line>;<optimization>; <function name>;<element type> For example, the reports listed below report the following information: Linux and Mac OS X: <sample1.f90;-1:-1;hlo;foo_;0> Windows: <sample1.f90;-1:-1;hlo;_FOO;0>	• <*start line*>: Indicates the starting line number for the function being examined. A value of -1 means that the report applies to the entire function. • <*end line*>: Indicates the ending line number for the function being examined. • <*optimization*>: Indicates the optimization phase; for this report the indicated phase should be hlo. • <*function name*>: Name of the function being examined. • <*element type*>: Indicates the type of the report element; 0 indicates the element is a comment.

Several report elements grouped together.
`QLOOPS 2/2 ENODE LOOPS 2`
`unknown 0 multi_exit_do 0 do 2`
`linear_do 2`
`LINEAR HLO EXPRESSIONS: 17 / 18`
	Windows only: This section of the report lists the following information:
	• `QLOOPS`: Indicates the number of well-formed loops found out of the loops discovered.
	• `ENODE LOOPS`: Indicates number of preferred forms (canonical) of the loops generated by HLO. This indicates the number of loops generated by HLO.
	• `unknown`: Indicates the number of loops that could not be counted.
	• `multi_exit_do`: Indicates the countable loops containing multiple exits.
	• `do`: Indicates the total number of loops with trip counts that can be counted.
	• `linear_do`: Indicates the number of loops with bounds that can be represented in a linear form.

Report Element	Description
	• LINEAR HLO EXPRESSIONS: Indicates the number of expressions (first number) in all of the intermediate forms (ENODE) of the expression (second number) that can be represented in a linear form.

The code sample list above will result in a report output similar to the following.

Operating System	Example 1 Report Output
Linux and Mac OS X	<sample1.f90;-1:-1;hlo;foo_;0> High Level Optimizer Report (foo_) Block, Unroll, Jam Report: (loop line numbers, unroll factors and type of transformation) <sample1.f90;7:7;hlo_unroll;foo_;0> Loop at line 7 unrolled with remainder by 2
Windows	<sample1.f90;-1:-1;hlo;_FOO;0> High Level Optimizer Report (_FOO) QLOOPS 2/2 ENODE LOOPS 2 unknown 0 multi_exit_do 0 do 2 linear_do 2 LINEAR HLO EXPRESSIONS: 17 / 18 _____ C:\samples\sample1.f90;6:6;hlo_linear_trans;_FOO;0> Loop Interchange not done due to: User Function Inside Loop Nest Advice: Loop Interchange, if possible, might help Loopnest at lines: 6 7 : Suggested Permutation: (1 2) --> (2 1)

Example 2: This example illustrates the condition where the loop nesting prohibits interchange.

Example 2

```
subroutine foo (A, B, bound)
   integer i,j,n,bound
   integer A(bound), B(bound,bound)
   n = bound
   do j = 1, n
```

Example 2

```
      A(j) = j + B(1,j)
      do i = 1, n
        B(j,i) = B(j,i) + A(j)
      end do
   end do
   return
end subroutine foo
```

The code sample listed above will result in a report output similar to the following.

Operating System	Example 2 Report Output
Linux and Mac OS X	<sample2.f90;-1:-1;hlo;foo_;0> High Level Optimizer Report (foo_) Block, Unroll, Jam Report: (loop line numbers, unroll factors and type of transformation) <sample2.f90;8:8;hlo_unroll;foo_;0> Loop at line 8 unrolled with remainder by 2
Windows	<sample2.f90;-1:-1;hlo;_FOO;0> High Level Optimizer Report (_FOO) QLOOPS 2/2 ENODE LOOPS 2 unknown 0 multi_exit_do 0 do 2 linear_do 2 LINEAR HLO EXPRESSIONS: 24 / 24 --- C:\samples\sample2.f90;6:6;hlo_linear_trans;_FOO;0> Loop Interchange not done due to: Imperfect Loop Nest (Either at Source or due t o other Compiler Transformations) Advice: Loop Interchange, if possible, might help Loopnest at lines: 6 8 : Suggested Permutation: (1 2) --> (2 1)

Example 3: This example illustrates the condition where data dependence prohibits loop interchange.

Example 3

```
subroutine foo (bound)
   integer i,j,n,bound
   integer A(100,100), B(100,100), C(100,100)
```

Example 3

```
   equivalence (B(2),A)
   n = bound
   do j = 1, n
      do i = 1, n
        A(j,i) = C(j,i) * 2
        B(j,i) = B(j,i) + A(j,i) * C(j,i)
      end do
   end do
   return
end subroutine foo
```

The code sample listed above will result in a report output similar to the following.

Operating System	Example 3 Report Output
Linux and Mac OS X	<sample3.f90;-1:-1;hlo;foo_;0> High Level Optimizer Report (foo_) <sample3.f90;8:8;hlo_scalar_replacement;in foo_;0> #of Array Refs Scalar Replaced in foo_ at line 8=2 Block, Unroll, Jam Report: (loop line numbers, unroll factors and type of transformation) <sample3.f90;8:8;hlo_unroll;foo_;0> Loop at line 8 unrolled with remainder by 2
Windows	<sample3.f90;-1:-1;hlo;_FOO;0> High Level Optimizer Report (_FOO) QLOOPS 2/2 ENODE LOOPS 2 unknown 0 multi_exit_do 0 do 2 linear_do 2 LINEAR HLO EXPRESSIONS: 24 / 24 ——————————————————————— C:\samples\sample3.f90;8:8;hlo_scalar_replacement;in _FOO ;0> #of Array Refs Scalar Replaced in _FOO at line 8=1 C:\samples\3.f90;7:7;hlo_linear_trans;_FOO;0> Loop Interchange not done due to: Data Dependencies Dependencies found between following statements: [From_Line# -> (Dependency Type) To_Line#] [9 ->(Flow) 10] [9 ->(Output) 10] [10

Operating System	Example 3 Report Output
	->(Anti) 10] [10 ->(Anti) 9] [10 ->(Output) 9] Advice: Loop Interchange, if possible, might help Loopnest at lines: 7 8 : Suggested Permutation: (1 2) --> (2 1)

Example 4: This example illustrates the condition where the loop order was determined to be proper, but loop interchange might offer only marginal relative improvement.

Example 4

```
subroutine foo (A, B, bound, value)
   integer i,j,n,bound,value
   integer A(bound, bound), B(bound,bound)
   n = bound
   do j = 1, n
      do i = 1, n
        A(i,j) = A(i,j) + B(j,i)
      end do
   end do
   value = A(1,1)
   return
end subroutine foo
```

The code sample listed above will result in a report output similar to the following.

Operating System	Example 4 Report Output
Linux and Mac OS X	<sample4.f90;-1:-1;hlo;foo_;0> High Level Optimizer Report (foo_) Block, Unroll, Jam Report: (loop line numbers, unroll factors and type of transformation) <sample4.f90;7:7;hlo_unroll;foo_;0> Loop at line 7 unrolled with remainder by 2
Windows	<sample4.f90;-1:-1;hlo;_FOO;0> High Level Optimizer Report (_FOO) QLOOPS 2/2 ENODE LOOPS 2 unknown 0 multi_exit_do 0 do 2 linear_do 2 LINEAR HLO EXPRESSIONS: 18 / 18

Example 5: This example illustrates the conditions where the loop nesting was imperfect and the loop order was good, but loop interchange would offer marginal relative improvements.

Example

```
subroutine foo (A, B, C, bound, value)
   integer i,j,n,bound,value
   integer A(bound, bound), B(bound,bound), C(bound, bound)
   n = bound
   do j = 1, n
      value = value + A(1,1)
      do i = 1, n
        value = B(i,j) + C(j,i)
      end do
   end do
   return
```

Example
`end subroutine foo`

The code sample listed above will result in a report output similar to the following.

Operating System	Example 5 Report Output
Linux and Mac OS X	<sample5.f90;-1:-1;hlo;foo_;0> High Level Optimizer Report (foo_) Loopnest Preprocessing Report: <sample5.f90;7:8;hlo;foo_;0> Preprocess Loopnests <foo_>: Moving Out Store @Line<8> in Loop @Line<7>
Windows	<sample5.f90;-1:-1;hlo;_FOO;0> High Level Optimizer Report (_FOO) QLOOPS 2/2 ENODE LOOPS 2 unknown 0 multi_exit_do 0 do 2 linear_do 2 LINEAR HLO EXPRESSIONS: 20 / 25 --- Loopnest Preprocessing Report: C:\samples\sample5.f90;7:8;hlo;_FOO;0> Preprocess Loopnests <_FOO>: Moving Out Store @Line<8> in Loop @Line<7> C:\samples\sample5.f90;5:5;hlo_linear_trans;_FOO;0> Loop Interchange not done due to: Imperfect Loop Nest (Either at Source or due t o other Compiler Transformations) Advice: Loop Interchange, if possible, might help Loopnest at lines: 5 7 : Suggested Permutation: (1 2) --> (2 1)

Changing Code Based on the Report Results

While the HLO report tells you what loop transformations the compiler performed and provides some advice, the omission of a given loop transformation might imply that there are transformations the compiler might attempt. The following list suggests some transformations you might want to apply. (Manual optimization techniques, like manual cache blocking, should

be avoided or used only as a last resort.)

- Loop Interchanging - Swap the execution order of two nested loops to gain a cache locality or unit-stride access performance advantage.
- Distributing - Distribute or split up one large loop into two smaller loops. This strategy might provide an advantage when too many registers are being consumed in a large loop.
- Fusing - Fuse two smaller loops with the same trip count together to improve data locality.
- Loop Blocking - Use cache blocking to arrange a loop so it will perform as many computations as possible on data already residing in cache. (The next block of data is not read into cache until computations using the first block are finished.)
- Unrolling - Unrolling is a way of partially disassembling a loop structure so that fewer numbers of iterations of the loop are required; however, each resulting loop iteration is larger. Unrolling can be used to hide instruction and data latencies, to take advantage of floating point loadpair instructions, and to increase the ratio of real work done per memory operation.
- Prefetching - Request the compiler to bring data in from relatively slow memory to a faster cache several loop iterations ahead of when the data is actually needed.
- Load Pairing - Use an instruction to bring two floating point data elements in from memory in a single step.

High Performance Optimizer (HPO) Report

The following command examples illustrate the general command needed to create HPO report with combined options.

Operating System	Example Command
Linux* and Mac OS* X	`ifort -opt-report 0 -opt-report-phasehpo sample.f90`
Windows*	`ifort /Qopt-report:0 /Qopt-report-phase:hpo sample.f90`

Use `-opt-report-help` (Linux and Mac OS X) or `/Qopt-report-help` (Windows) to list the names of HPO report categories.

You must specify different compiler options to use the specific HPO report categories.

- For OpenMP*, add `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows) to the command line.

- For parallelism, add `-parallel` (Linux and Mac OS X) or `/Qparallel` (Windows) to the command line.
- For vectorization, add `-x` (Linux and Mac OS X) or `/Qx` (Windows) to the command line; valid processor values are `SSE4.1`, `SSSE3`, `SSE3`, and `SSE2`.

Parallelism Report

The `-par-report` (Linux* and Mac OS* X) or `/Qpar-report` (Windows*) option controls the diagnostic levels 0, 1, 2, or 3 of the auto-parallelizer. Specify a value of 3 to generate the maximum diagnostic details.

Run the diagnostics report by entering commands similar to the following:

Operating System	Commands
Linux and Mac OS X	`ifort -c -parallel -par-report 3 sample.f90`
Windows	`ifort /c /Qparallel /Qpar-report:3 sample.f90`

where `-c` (Linux and Mac OS X) or `/c` (Windows) instructs the compiler to compile the example without generating an executable.

NOTE. Linux and Mac OS X: The space between the option and the phase is optional. Windows: The colon between the option and phase is optional.

For example, assume you want a full diagnostic report on the following example code:

Example

```
subroutine no_par(a, MAX)
   integer :: i, a(MAX)
   do i = 1, MAX
     a(i) = mod((i * 2), i) * 1 + sqrt(3.0)
     a(i) = a(i-1) + i
   end do
end subroutine no_par
```

The following example output illustrates the diagnostic report generated by the compiler for the example code shown above. In most cases, the comment listed next to the line is self-explanatory.

Example Report Output

`procedure: NO_PAR`
 	
`sample.f90(7):(4) remark #15049: loop was not parallelized: loop is not a parallelization candidate`
 	
`sample.f90(7):(4) remark #15050: loop was not parallelized: existence of parallel dependence`
 	
`sample.f90(13):(6) remark #15051: parallel dependence: proven FLOW dependence between A line 13, and A line 13`

Responding to the results

The `-par-threshold{n)` (Linux* and Mac OS* X) or `/Qpar-threshold[:n]` (Windows*) option sets a threshold for auto-parallelization of loops based on the probability of profitable execution of the loop in parallel. The value of *n* can be from 0 to 100. You can use `-par-threshold0` (Linux and Mac OS X) or `/Qpar-threshold:0` (Windows) to auto-parallelize loops regardless of computational work.

Use `-ipo[value]` (Linux and Mac OS X) or `/Qipo` (Windows) to eliminate assumed side-effects done to function calls.

Use the `!DEC$ PARALLEL` directive to eliminate assumed data dependency.

Software Pipelining (SWP) Report (Linux* and Windows*)

The SWP report can provide details information about loops currently taking advantage of software pipelining available on IA-64 architecture based systems. The report can suggest reasons why the loops are not being pipelined.

The following command syntax examples demonstrates how to generate a SWP report for the Itanium® Compiler Code Generator (ECG) Software Pipeliner (SWP).

Operating System	Syntax Examples
Linux*	`ifort -c -opt-report -opt-report-phase=ecg_swp sample.f90`

Operating System	Syntax Examples
Windows*	`ifort /c /Qopt-report /Qopt-report-phase:ecg_swp sample.f90`

where `-c` (Linux) or `/c` (Windows) tells the compiler to stop at generating the object code (no linking occurs), `-opt-report` (Linux) or `/Qopt-report` (Windows) invokes the report generator, and `-opt-report-phase=ecg_swp` (Linux) or `/Qopt-report-phase:ecg_swp` (Windows) indicates the phase (ecg) for which to generate the report.

You can use `-opt-report-file` (Linux) or `/Qopt-report-file` (Windows) to specify an output file to capture the report results. Specifying a file to capture the results can help to reduce the time you spend analyzing the results and can provide a baseline for future testing.

Typically, loops that software pipeline will have a line that indicates the compiler has scheduled the loop for SWP in the report. If the `-O3` (Linux) or `/O3` (Windows) option is specified, the SWP report merges the loop transformation summary performed by the loop optimizer.

Some loops will not software pipeline (SWP) and others will not vectorize if function calls are embedded inside your loops. One way to get these loops to SWP or to vectorize is to inline the functions using IPO.

You can compile this example code to generate a sample SWP report. The sample reports is also shown below.

Example

```
!#define NUM 1024
subroutine multiply_d(a,b,c,NUM)
  implicit none
  integer :: i,j,k,NUM
  real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
  NUM=1024
  do i=0,NUM
    do j=0,NUM
      do k=0,NUM
        c(j,i) = c(j,i) + a(j,k) * b(k,i)
      end do
    end do
  end do
end subroutine multiply_d
```

The following sample report shows the report phase that results from compiling the example code shown above (when using the `ecg_swp` phase).

Sample SWP Report

```
Swp report for loop at line 10 in _Z10multiply_dPA1024_dS0_S0_ in file SWP report.f90
 Resource II  = 2
 Recurrence II = 2
 Minimum II  = 2
 Scheduled II = 2

 Estimated GCS II   = 7
```

Sample SWP Report

```
Percent of Resource II needed by arithmetic ops  = 100%
Percent of Resource II needed by memory ops  =  50%
Percent of Resource II needed by floating point ops =  50%
Number of stages in the software pipeline = 6
```

Reading the Reports

To understand the SWP report results, you must know something about the terminology used and the related concepts. The following table describes some of the terminology used in the SWP report.

Term	Definition
II	Initiation Interval (II). The number of cycles between the start of one iteration and the next in the SWP. The presence of the term II in any SWP report indicates that SWP succeeded for the loop in question. II can be used in a quick calculation to determine how many cycles your loop will take, if you also know the number of iterations. Total cycle time of the loop is approximately N * Scheduled II + number Stages (Where N is the number of iterations of the loop). This is an approximation because it does not take into account the ramp-up and ramp-down of the prolog and epilog of the SWP, and only considers the kernel of the SWP loop. As you modify your code, it is generally better to see scheduled II go down, though it is really N* (Scheduled II) + Number of stages in the software pipeline that is ultimately the figure of merit.

Term	Definition
Resource II	Resource II implies what the Initiation Interval should be when considering the number of functional units available.
Recurrence II	Recurrence II indicates what the Initiation Interval should be when there is a recurrence relationship in the loop. A recurrence relationship is a particular kind of a data dependency called a flow dependency like `a[i] = a[i-1]` where `a[i]` cannot be computed until `a[i-1]` is known. If Recurrence II is non-zero and there is no flow dependency in the code, then this indicates either Non-Unit Stride Access or memory aliasing. See Helping the Compiler for more information.
Minimum II	Minimum II is the theoretical minimum Initiation Interval that could be achieved.
Scheduled II	Scheduled II is what the compiler actually scheduled for the SWP.
number of stages	Indicates the number of stages. For example, in the report results below, the line "Number of stages in the software pipeline = 3" indicates there were three stages of work, which will show, in assembly, to be a load, an FMA instruction and a store.
loop-carried memory dependence edges	The loop-carried memory dependence edges means the compiler avoided WAR (Write After Read) dependency. Loop-carried memory dependence edges can indicate problems with memory aliasing. See Helping the Compiler.

Using the Report to Resolve Issues

One fast way to determine if specific loops have been software pipelined is to look for "r;Number of stages in the software pipeline" in the report; the phrase indicates that software pipelining for the associated loop was successfully applied.

Analyze the loops that did not SWP in order to determine how to enable SWP. If the compiler reports the "Loop was not SWP because...", see the following table for suggestions about how to correct possible problems:

Message in Report	Suggested Action
acyclic global scheduler can achieve a better schedule: => loop not pipelined	Indicates that the most likely cause is memory aliasing issues. For memory alias problems see memory aliasing (restrict, `#pragma ivdep`). Might indicate the application is accessing memory in a non-Unit Stride fashion. Non-Unit Stride issues may be indicated by an artificially high recurrence II; If you know there is no recurrence relationship (`a[i] = a[i-1] + b[i]`) in the loop, then a high recurrence II (greater than 0) is a sign that you are accessing memory non-Unit Stride. Rearranging code, perhaps a loop interchange, might help mitigate this problem.
Loop body has a function call	Indicates inlining the function might help solve the problem.
Not enough static registers	Indicates you should distribute the loop by separating it into two or more loops. On IA-64 architecture based systems you may use `#pragma distribute point`.
Not enough rotating registers	Indicates the loop carried values use the rotating registers. Distribute the loop.
Loop too large	Indicates you should distribute the loop.

Message in Report	Suggested Action
	On IA-64 architecture based systems you may use the `#pragma distribute point`.
Loop has a constant trip count < 4	Indicates unrolling was insufficient. Attempt to fully unroll the loop. However, with small loops fully unrolling the loop is not likely to affect performance significantly.
Too much flow control	Indicates complex loop structure. Attempt to simplify the loop.

Index variable type used can greatly impact performance. In some cases, using loop index variables of type short or unsigned int can prevent software pipelining. If the report indicates performance problems in loops where the index variable is not int and if there are no other obvious causes, try changing the loop index variable to type int.

Vectorization Report

The vectorization report can provide information about loops that could take advantage of Intel® Streaming SIMD Extensions (Intel® SSE3, SSE2, and SSE) vectorization, and it is available on systems based on IA-32 and Intel® 64 architectures.

See Using Parallelism for information on other vectorization options.

The `-vec-report` (Linux* and Mac OS* X) or `/Qvec-report` (Windows*) option directs the compiler to generate the vectorization reports with different levels of information. Specify a value of 3 to generate the maximum diagnostic details.

Operating System	Command
Linux and Mac OS X	`ifort -c -xSSSE3 -vec-report3 sample.f90`
Windows	`ifort /c /QxSSSE3 /Qvec-report:3 sample.f90`

where `-c` (Linux and Mac OS X) or `/c` (Windows) instructs the compiler to compile the example without generating an executable.

NOTE. Linux and Mac OS X: The space between the option and the phase is optional.

Windows: The colon between the option and phase is optional.

The following example results illustrate the type of information generated by the vectorization report:

Example results

```
sample.f90(27) : (col. 9) remark: loop was not vectorized: not inner loop.

sample.f90(28) : (col. 11) remark: LOOP WAS VECTORIZED.

sample.f90(31) : (col. 9) remark: loop was not vectorized: not inner loop.

sample.f90(32) : (col. 11) remark: LOOP WAS VECTORIZED.

sample.f90(37) : (col. 10) remark: loop was not vectorized: not inner loop.

sample.f90(38) : (col. 12) remark: loop was not vectorized: not inner loop.

sample.f90(40) : (col. 14) remark: loop was not vectorized: vectorization possible but
seems inefficient.

sample.f90(46) : (col. 10) remark: loop was not vectorized: not inner loop.

sample.f90(47) : (col. 12) remark: loop was not vectorized: contains unvectorizable
statement at line 48.
```

If the compiler reports "r;Loop was not vectorized" because of the existence of vector dependence, then you should analyze the loop for vector dependence. If you determine there is no legitimate vector dependence, then the message indicates that the compiler was assuming the pointers or arrays in the loop were dependent, which implies the pointers or arrays were aliased. Use memory disambiguation techniques to resolve these cases.

There are three major types of vector dependence: `FLOW`, `ANTI`, and `OUTPUT`.

There are a number of situations where the vectorization report may indicate vector dependencies. The following situations will sometimes be reported as vector dependencies, non-unit stride, low trip count, and complex subscript expression.

Non-Unit Stride

The report might indicate that a loop could not be vectorized when the memory is accessed in a non-Unit Stride manner. This means that nonconsecutive memory locations are being accessed in the loop. In such cases, see if loop interchange can help or if it is practical. If not then you can force vectorization sometimes through `vector always` directive; however, you should verify improvement.

See Understanding Runtime Performance for more information about non-unit stride conditions.

Usage with Other Options

The vectorization reports are generated during the final compilation phase, which is when the executable is generated; therefore, there are certain option combinations you cannot use if you are attempting to generate a report. If you use the following option combinations, the compiler issues a warning and does not generate a report:

- `-c` or `-ipo` or `-x` with `-vec-report` (Linux* and Mac OS* X) and `/c` or `/Qipo` or `/Qx` with `/Qvec-report` (Windows*)
- `-c` or `-ax` with `-vec-report` (Linux and Mac OS X) and `/c` or `/Qax` with `/Qvec-report` (Windows)

The following example commands can generate vectorization reports:

Operating System	Command Examples
Linux and Mac OS X	`ifort -xSSSE3 -vec-report3 sample.f90` `ifort -xSSSE3 -ipo -vec-report3 sample.f90`
Windows	`ifort /QxSSSE3 /Qvec-report:3 sample.f90` `ifort /QxSSSE3 /Qipo /Qvec-report:3 sample.f90`

Responding to the Results

You might consider changing existing code to allow vectorization under the following conditions:

- The vectorization report indicates that the program "contains unvectorizable statement at line XXX".
- The vectorization report states there is a "vector dependence: proven FLOW dependence between 'r;variable' line XXX, and 'r;variable' line XXX" or "loop was not vectorized: existence of vector dependence." Generally, these conditions indicate true loop dependencies are stopping vectorization. In such cases, consider changing the loop algorithm.

For example, consider the two equivalent algorithms producing identical output below. "Foo" will not vectorize due to the FLOW dependence but "bar" does vectorize.

Example

```
subroutine foo(y)
  implicit none
  integer :: i
  real :: y(10)
  do i=2,10
    y (i) = y (i-1)+1
  end do
end subroutine foo
subroutine bar(y)
  implicit none
  integer :: i
  real :: y(10)
  do i=2,10
    y (i) = y (1)+i
  end do
end subroutine bar
```

Unsupported loop structures may prevent vectorization. An example of an unsupported loop structure is a loop index variable that requires complex computation. Change the structure to remove function calls to loop limits and other excessive computation for loop limits.

Example

```
function func(n)
  implicit none
  integer :: func, n
  func = n*n-1
end function func
subroutine unsupported_loop_structure(y,n)
  implicit none
  integer :: i,n, func
  real :: y(n)
  do i=0,func(n)
    y(i) = y(i) * 2.0
  end do
end subroutine unsupported_loop_structure
```

Non-unit stride access might cause the report to state that "vectorization possible but seems inefficient". Try to restructure the loop to access the data in a unit-stride manner (for example, apply loop interchange), or try directive .

Using mixed data types in the body of a loop might prevent vectorization. In the case of mixed data types, the vectorization report might state something similar to "loop was not vectorized: condition too complex".

The following example code demonstrates a loop that cannot vectorize due to mixed data types within the loop. For example, `withinborder` is an integer while all other data types in loop are not. Simply changing the `withinborder` data type will allow this loop to vectorize.

Example

```
subroutine howmany_close(x,y,n)
  implicit none
  integer :: i,n,withinborder
  real :: x(n), y(n), dist
  withinborder=0
  do i=0,100
    dist=sqrt(x(i)*x(i) + y(i)*y(i))
    if (dist<5) withinborder= withinborder+1
  end do
end subroutine howmany_close
```

OpenMP* Report

The `-openmp-report` (Linux* and Mac OS* X) or `/Qopenmp-report` (Windows*) option controls the diagnostic levels for OpenMP* reporting. The OpenMP* report information is not generated unless you specify the option with a value of either 1 or 2. Specifying 2 provides the most useful information.

You must specify the `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows) along with this option.

Linux OS and Mac OS X	Windows OS	Description
`-openmp-report 2`	`/Qopenmp-report:2`	Report results are same as when specifying 1 except the results also include diagnostics indicating constructs, like directives, that were handled successfully. This is the recommend level.

Linux OS and Mac OS X	Windows OS	Description
`-openmp-report 1`	`/Qopenmp-report:1`	Reports on loops, regions, and sections that were parallelized successfully. This is the default level.
`-openmp-report 0`	`/Qopenmp-report:0`	No diagnostics report generated.

The following example commands demonstrate how to run the report using the combined commands.

Operating System	Syntax Examples
Linux and Mac OS X	`ifort -openmp -openmp-report 2 sample1.f90 sample2.f90`
Windows	`ifort /Qopenmp /Qopenmp-report:2 sample1.f90 sample2.f90`

NOTE. Linux and Mac OS X: The space between the option and the level is optional.

Windows: The colon between the option and level is optional.

The following example results illustrate the typical format of the generated information:

Example results
`openmp_sample.f90(77): (col. 7) remark : OpenMP DEFINED LOOP WAS PARALLELIZED.`
`openmp_sample.f90(68): (col. 7) remark: OpenMP DEFINED REGION WAS PARALLELIZED.`

25 Using Compiler Optimizations

Automatic Optimizations Overview

Intel® compilers allow you to compile applications for processors based on IA-32 architectures (32-bit applications), Intel® 64 architectures (32-bit and 64-bit applications), or IA-64 architectures (64-bit applications).

By default the compiler chooses a set of optimizations that balances compile-time and run-time performance for your application. Also, you can manually select optimizations based on the specific needs of the application.

The following table summarizes the common optimization options you can use for quick, effective results.

Linux* and Mac OS* X	Windows*	Description
`-O3`	`/O3`	Enables aggressive optimization for code speed. Recommended for code with loops that perform substantial calculations or process large data sets.
`-O2` (or `-O`)	`/O2`	Affects code speed. This is the default option; the compiler uses this optimization level if you do not specify anything.
`-O1`	`/O1`	Affects code size and locality. Disables specific optimizations.
`-fast`	`/fast`	Enables a collection of common, recommended optimizations for run-time performance. Can introduce architecture dependency.
`-O0`	`/Od`	Disables optimization. Use this for rapid compilation while debugging an application.

The variety of automatic optimizations enable you to quickly enhance your application performance. In addition to automatic optimizations, the compiler invokes other optimization enabled with source code directives, optimized library routines, and performance-enhancing utilities.

The remaining topics in this section provide more details on the automatic optimizations supported in the Intel compilers.

Enabling Automatic Optimizations

This topic lists the most common code optimization options, describes the characteristics shared by IA-32, Intel® 64, and IA-64 architectures, and describes the general behavior for each architecture.

The architectural differences and compiler options enabled or disabled by these options are also listed in more specific detail in the associated Compiler Options topics; therefore, each option discussion listed below includes a link to the appropriate reference topic.

Linux* and Mac OS* X	Windows*	Description
-O1	/O1	Optimizes to favor smaller code size and code locality. In most cases, -O2 (Linux* OS and Mac OS* X) or /O2 (Windows* OS) is recommended over this option. This optimization disables some optimizations that normally increase code size. This level might improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops. In general, this optimization level does the following:

Linux* and Mac OS* X	Windows*	Description
		• Enables global optimization. • Disables intrinsic recognition and inlining of intrinsics. IA-64 architecture: • The option disables software pipelining, loop unrolling, and global code scheduling.
-O2 or -O	/O2	Optimizes for code speed. Since this is the default optimization, if you do not specify an optimization level the compiler will use this optimization level automatically. This is the generally recommended optimization level; however, specifying other compiler options can affect the optimization normally gained using this level. In general, the resulting code size will be larger than the code size generated using -O1 (Linux and Mac OS X) or /O1 (Windows). This option enables the following capabilities for performance gain: inlining intrinsic functions, constant propagation, copy propagation, dead-code elimination, global register allocation, global instruction scheduling and control speculation, loop unrolling,

Linux* and Mac OS* X	Windows*	Description
		optimized code selection, partial redundancy elimination, strength reduction/induction variable simplification, variable renaming, exception handling optimizations, tail recursions, peephole optimizations, structure assignment lowering optimizations, and dead store elimination. For IA-32 and Intel 64 architectures: • Enables certain optimizations for speed, such as vectorization. IA-64 architecture: • Enables optimizations for speed, including global code scheduling, software pipelining, predication, speculation, and data prefetch.
-O3	/O3	Enables -O2 (Linux and Mac OS X) or /O2 (Windows) optimizations, as well as more aggressive optimizations, including prefetching, scalar replacement, cache blocking, and loop and memory access transformations. As compared to -O2 (Linux) or /O2 (Windows), the optimizations enabled by this option often result in faster program execution, but can

Linux* and Mac OS* X	Windows*	Description
		slow down code execution in some cases. Using this option may result in longer compilation times. This option is recommended for loop-intensive applications that perform substantial floating-point calculations or process large data sets.
-fast	/fast	Provides a single, simple optimization that enables a collection of optimizations that favor run-time performance. This is a good, general option for increasing performance in many programs. For IA-32 and Intel 64 architectures, the -xSSSE3 (Linux and Mac OS X) or /QxSSSE3 (Windows) option that is set by this option cannot be overridden by other command line options. If you specify this option along with a different processor-specific option, such as -xSSE2 (Linux) or /QxSSE2 (Windows), the compiler will issue a warning stating the -xSSSE3 or /QxSSSE3 option cannot be overridden; the best strategy for dealing with this restriction is to explicitly specify the options you want to set from the command line.

Linux* and Mac OS* X	Windows*	Description
		CAUTION. Programs compiled with the -xSSSE3 (Linux and Mac OS X) or /QxSSSE3 (Windows) option will detect non-compatible processors and generate an error message during execution. While this option enables other options quickly, the specific options enabled by this option might change from one compiler release to the next. Be aware of this possible behavior change in the case where you use makefiles.

The following syntax examples demonstrate using the default option to compile an application:

Operating System	Example
Linux and Mac OS X	`ifort -O2 prog.f90`
Windows	`ifort /O2 prog.f90`

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

Targeting IA-32 and Intel(R) 64 Architecture Processors Automatically

The -x (Linux* and Mac OS* X) or /Qx (Windows*) option can automatically optimize your application for specific Intel® processors based on IA-32 and Intel® 64 architectures.

The automatic optimizations allow you to take advantage of the architectural differences, new instruction sets, or advances in processor design; however, the resulting, optimized code might contain unconditional use of features that are not supported on other, earlier processors. Therefore, using these options effectively sets a minimum hardware requirement for your application.

The optimizations can include generating Intel® Streaming SIMD Extensions 4 (SSE4), Supplemental Streaming SIMD Extensions 3 (SSSE3), Streaming SIMD Extensions 3 (SSE3), Streaming SIMD Extensions 2 (SSE2), or Streaming SIMD Extensions (SSE) instructions.

If you intend to run your programs on multiple processors based on IA-32 or Intel® 64 architectures, do not use this option; instead, consider using the `-ax` (Linux and Mac OS X) or `/Qax` (Windows) option to achieve both processor-specific performance gains and portability among different processors.

Linux OS and Mac OS X	Windows OS	Description
`-xHost`	`/QxHost`	Can generate instructions for the highest instruction set and processor available on the compilation host.
`-xAVX`	`/QxAVX`	Optimizes for Intel processors that support Intel® Advanced Vector Extensions (Intel® AVX).
`-xSSE4.1`	`/QxSSE4.1`	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture. This replaces value S, which is deprecated.
`-xSSE4.2`	`/QxSSE4.2`	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE

Linux OS and Mac OS X	Windows OS	Description
		instructions and it can optimize for the Intel® Core™ processor family.
-xSSSE3	/QxSSSE3	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. This replaces value T, which is deprecated.
-xSSE3_ATOM	/QxSSE3_ATOM	Optimizes for the Intel® Atom™ processor and Intel® Centrino® Atom™ Processor Technology. Can generate MOVBE instructions, depending on the setting of option -minstruction (Linux and Mac OS) or /Qinstruction (Windows). Mac OS X: Supported on IA-32 architectures.
-xSSE3	/QxSSE3	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. This replaces value P, which is deprecated. Mac OS X: Supported on IA-32 architectures.
-xSSE2	/QxSSE2	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium®

Linux OS and Mac OS X	Windows OS	Description
		4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2. Mac OS X: Not supported.

Certain keywords for compiler options -m and /arch produce binaries that should run on processors not made by Intel that implement the same capabilities as the corresponding Intel processors. For details, see Compiler Options.

To prevent illegal instruction and similar unexpected run-time errors during program execution, the compiler inserts code in the main routine of the program to check for proper processor usage. Using this option limits you to a minimum processor level. For example, if you target an application to run on Intel® Xeon® processors based on the Intel® Core™ microarchitecture, it is unlikely the resulting application will operate correctly on earlier Intel processors.

If you target more than one processor value, the resulting code will be generated for the highest-performing processor specified if the compiler determines there is an advantage in doing so. The highest- to lowest-performing processor values are as follows:

1. SSE4.1
2. SSSE3
3. SSE3
4. SSE2

Executing programs compiled with processor values of SSE4.1, SSSE3, SSE3, or SSE2 on unsupported processors will display a run-time error. For example, if you specify the SSSE3 processor value to compile an application but execute the application on an Intel® Pentium® 4 processor, the application generates an error similar to the following:

Run-time Error

```
Fatal Error: This program was not built to run on the processor in your
system.

The allowed processors are: Intel(R) Core(TM) Duo processors and compatible
Intel processors with supplemental Streaming SIMD Extensions 3 (SSSE3)
instruction support.
```

The following examples demonstrate compiling an application for Intel® Core™2 Duo processor and compatible processors. The resulting binary might not execute correctly on earlier processors or on IA-32 architecture processors not made by Intel Corporation.

Operating System	Example
Linux and Mac OS X	`ifort -xSSSE3 sample.f90`
Windows	`ifort /QxSSSE3 sample.f90`

Targeting Multiple IA-32 and Intel(R) 64 Architecture Processors for Run-time Performance

The `-ax` (Linux* and Mac OS* X) or `/Qax` (Windows*) option instructs the compiler to determine if opportunities exist to generate multiple, specialized code paths to take advantage of performance gains and features available on newer Intel® processors based on IA-32 and Intel® 64 architectures. This option also instructs the compiler to generate a more generic (baseline) code path that should allow the same application to run on a larger number of processors; however, the baseline code path is usually slower than the specialized code.

The compiler inserts run-time checking code to help determine which version of the code to execute. The size of the compiled binary increases because it contains both a processor-specific version of some of the code and a generic baseline version of all code. Application performance is affected slightly due to the run-time checks needed to determine which code to use. The code path executed depends strictly on the processor detected at run time.

Processor support for the baseline code path is determined by the processor family or instruction set specified in the `-m` or `-x` (Linux and Mac OS X) or `/arch` or `/Qx` (Windows) option, which has default values for each architecture.

This allows you to impose a more strict processor or instruction set requirement for the baseline code path; however, such generic baseline code will not operate correctly on processors that are not compatible with the minimum processor or instruction set requirement. For the IA-32 architecture, you can specify a baseline code path that will work on all IA-32 compatible processors using the `-mia32` (Linux) or `/arch:IA32` (Windows) options. You should always specify the processor or instruction set requirements explicitly for the baseline code path, rather than depend on the defaults for the architecture.

Optimizations in the specialized code paths can include generating and using Intel® Streaming SIMD Extensions 4 (SSE4), Supplemental Streaming SIMD Extensions 3 (SSSE3), Streaming SIMD Extensions 3 (SSE3), or Streaming SIMD Extensions 2 (SSE2) instructions for supported Intel processors; however, such specialized code paths are executed only after checking verifies that the code is supported by the run-time host processor.

If not indicated otherwise, the following processor values are valid for IA-32 and Intel® 64 architectures.

Linux OS and Mac OS X	Windows OS	Description
-axSSE4.2	/QaxSSE4.2	Can generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions supported by Intel® Core™ i7 processors. Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for the Intel® Core™ processor family.
-axSSE4.1	/QaxSSE4.1	Can generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel processors. Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions and it can optimize for Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture. This replaces value S, which is deprecated. Mac OS X: IA-32 and Intel® 64 architectures.
-axSSSE3	/QaxSSSE3	Can generate Intel® SSSE3, SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for the Intel® Core™2 Duo processor family. This replaces value T, which is deprecated. Mac OS X: IA-32 architecture.

Linux OS and Mac OS X	Windows OS	Description
-axSSE3_ATOM	/QaxSSE3_ATOM	Optimizes for the Intel® Atom™ processor and Intel® Centrino® Atom™ Processor Technology. Can generate MOVBE instructions, depending on the setting of option -minstruction (Linux and Mac OS) or /Qinstruction (Windows). Mac OS X: Supported on IA-32 architectures.
-axSSE3	/QaxSSE3	Can generate Intel® SSE3, SSE2, and SSE instructions for Intel processors and it can optimize for processors based on Intel® Core™ microarchitecture and Intel NetBurst® microarchitecture. This replaces value P, which is deprecated. Mac OS X: IA-32 architecture.
-axSSE2	/QaxSSE2	Can generate Intel® SSE2 and SSE instructions for Intel processors, and it can optimize for Intel® Pentium® 4 processors, Intel® Pentium® M processors, and Intel® Xeon® processors with Intel® SSE2. Linux and Windows: IA-32 architecture.

NOTE. You can specify -diag-disable cpu-dispatch (Linux and Mac OS X) or /Qdiag-disable:cpu-dispatch (Windows) to disable the display of remarks about multiple code paths for CPU dispatch.

If your application for IA-32 or Intel® 64 architectures does not need to run on multiple processors , consider using the `-x` (Linux and Mac OS X) or `/Qx` (Windows) option instead of this option.

The following compilation examples demonstrate how to generate an IA-32 architecture executable that includes an optimized version for Intel® Core™2 Duo processors, as long as there is a performance gain, an optimized version for Intel® Core™ Duo processors, as long as there is a performance gain, and a generic baseline version that runs on any IA-32 architecture processor.

NOTE. If you combine the arguments, you must add a comma (",") separator between the individual arguments.

Operating System	Example
Linux	`ifort -axSSSE3,SSE3 -mia32 sample.f90`
Windows	`ifort /QaxSSSE3,SSE3 /arch:IA32 sample.f90`

Targeting IA-64 Architecture Processors Automatically

The Intel compiler supports options that optimize application performance for Intel® Itanium® processors based on the IA-64 architecture.

Linux* OS	Windows* OS	Optimizes applications for...
`-mtune=itanium2-p9000`	`/G2-p9000`	Default. Dual-Core Intel® Itanium® 2 processor (9000 series)
`-mtune=itanium2`	`/G2`	Intel® Itanium® 2 processors

NOTE. Mac OS* X: These options are not supported.

While the resulting executable is backward compatible, generated code is optimized for specific processors; therefore, code generated with `-mtune=itanium2-p9000` (Linux) or `/G2-p9000` (Windows) will run correctly on Itanium® 2 processors.

The following examples demonstrate using the default options to target an Itanium® 2 processor (9000 series). The same binary will also run on Intel® Itanium® 2 processors.

Operating System	Example
Linux	`ifort -mtune=itanium2-p9000 prog.f90`
Windows	`ifort /G2-p9000 prog.f90`

Restricting Optimizations

The following table lists options that restrict the ability of the Intel® compiler to optimize programs.

Linux* and Mac OS* X	Windows*	Effect
`-O0`	`/Od`	Disables all optimizations. Use this during development stages where fast compile times are desired. Linux* and Mac OS* X: • Sets option `-fomit-frame-pointer` and option `-fmath-errno`. Windows*: • Use `/Od` to disable all optimizations while specifying particular optimizations, such as: `/Od /Ob1` (disables all optimizations, but only enables inlining) For more information, see the following topic: • `-O0` compiler option

Linux* and Mac OS* X	Windows*	Effect
-g	/Zi, /Z7	Generates symbolic debugging information in object files for use by debuggers. This option enables or disables other compiler options depending on architecture and operating system; for more information about the behavior, see the following topic: • -g compiler option
-fmath-errno, -fno-math-errno	No equivalent	Instructs the compiler to assume that the program tests errno after calls to math library functions. For more information, see the following topic: • -fmath-errno compiler option

Diagnostic Options

Linux and Mac OS X	Windows	Effect
-sox	/Qsox	Instructs the compiler to save the compiler options and version number in the executable. During the linking process, the linker places information strings into the resulting executable. Slightly increases file size, but using this option can make

Linux and Mac OS X	Windows	Effect
		identifying versions for regression issues much easier. For more information, see the following topic: • -sox compiler option

Using Parallelism: OpenMP* Support

26

OpenMP* Support Overview

The Intel® compiler supports the OpenMP* Version 3.0 API specification. For complete Fortran language support for OpenMP, see the OpenMP Application Program Interface Version 3.0 specification, which is available from the OpenMP web site (http://www.openmp.org/, click the Specifications link).

This version of the Intel compiler also introduces OpenMP API Version 3.0 API specification support, as described in the OpenMP web site (http://www.openmp.org/, click Specifications).

OpenMP provides symmetric multiprocessing (SMP) with the following major features:

- Relieves the user from having to deal with the low-level details of iteration space partitioning, data sharing, and thread creation, scheduling, and synchronization.
- Provides the benefit of the performance available from shared memory multiprocessor and multi-core processor systems on IA-32, Intel® 64, and IA-64 architectures, including those processors with Hyper-Threading Technology.

The compiler performs transformations to generate multithreaded code based on a developer's placement of OpenMP directives in the source program making it easy to add threading to existing software. The Intel compiler supports all of the current industry-standard OpenMP directives and compiles parallel programs annotated with OpenMP directives.

The compiler provides Intel-specific extensions to the OpenMP Version 3.0 specification including run-time library routines and environment variables. However, these extensions are only supported by the Intel compilers. A summary of the compiler options that apply to OpenMP* appears in OpenMP* Options Quick Reference.

Parallel Processing with OpenMP

To compile with OpenMP, you need to prepare your program by annotating the code with OpenMP directives in the form of the Fortran program comments. The Intel compiler processes the application and internally produces a multithreaded version of the code which is then compiled. The output is an executable with the parallelism implemented by threads that execute parallel regions or constructs. See Programming with OpenMP.

Using Other Compilers

The OpenMP specification does not define interoperability of multiple implementations; therefore, the OpenMP implementation supported by other compilers and OpenMP support in Intel compilers might not be interoperable. Even if you compile and build the entire application with one compiler, be aware that different compilers might not provide OpenMP source compatibility that would allow you to compile and link the same set of application sources with a different compiler and get the expected parallel execution results.

Intel compilers include two sets of OpenMP libraries, as described in OpenMP Source Compatibility and Interoperability with Other Compilers.

OpenMP* Options Quick Reference

These options are supported on IA-32, Intel® 64, and IA-64 architectures.

Linux* OS and Mac OS* X	Windows* OS	Description
-openmp	/Qopenmp	This option enables the parallelizer to generate multi-threaded code based on the OpenMP* directives. The code can be executed in parallel on both uniprocessor and multiprocessor systems. IA-64 architecture only: • Implies -opt-mem-band-with1 (Linux) or /Qopt-mem-bandwidth1 (Windows).
-openmp-report	/Qopenmp-report	This option controls the OpenMP parallelizer's level of diagnostic messages. To use this option, you must also specify -openmp (Linux and Mac OS X) or /Qopenmp (Windows).

Linux* OS and Mac OS* X	Windows* OS	Description
-openmp-stubs	/Qopenmp-stubs	This option enables compilation of OpenMP programs in sequential mode. The OpenMP directives are ignored and a stub OpenMP library is linked.
-openmp-profile	/Qopenmp-profile	This option enables analysis of OpenMP* applications. To use this option, you must have previously installed Intel® Thread Profiler, which is one of the Intel® Threading Analysis Tools. This option can adversely affect performance because of the additional profiling and error checking invoked to enable compatibility with the threading tools. Do not use this option unless you plan to use the Intel® Thread Profiler.
-openmp-lib	/Qopenmp-lib	This option lets you specify an OpenMP* run-time library to use for linking. The legacy OpenMP run-time library is not compatible with object files created using OpenMP run-time libraries supported in other compilers. The compatibility OpenMP run-time library is compatible with object files created using the Microsoft* OpenMP run-time library (vcomp) and GNU OpenMP run-time library (libgomp).

Linux* OS and Mac OS* X	Windows* OS	Description
-openmp-link	/Qopenmp-link	This option controls whether the compiler links to static or dynamic OpenMP run-time libraries. To link to the static OpenMP run-time library (RTL) and create a purely static executable, you must specify -openmp-link static (Linux and Mac OS X) or /Qopenmp-link (Windows). However, we strongly recommend you use the default setting, -openmp-link dynamic (Linux and Mac OS X) or /Qopenmp-link:dynamic (Windows).
-openmp-threadprivate	/Qopenmp-threadprivate	This option lets you specify an OpenMP* threadprivate implementation. The legacy OpenMP run-time library is not compatible with object files created using OpenMP run-time libraries supported in other compilers.

When both -openmp and -parallel (Linux OS and Mac OS X) or /Qopenmp and /Qparallel (Windows OS) are specified on the command line, the parallel option is only applied in loop nests that do not have OpenMP directives. For loop nests with OpenMP directives, only the openmp option is applied.

Refer to the following topics for information about OpenMP environment variable and run-time routines:

- OpenMP Environment Variables
- OpenMP Run-time Library Routines
- Intel Extension Routines to OpenMP

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

OpenMP* Source Compatibility and Interoperability with Other Compilers

Intel compilers include two sets of OpenMP libraries:

- The Compatibility OpenMP libraries, which provide compatibility with OpenMP support provided by certain versions of the Microsoft Visual C++* compiler on Windows* OS, certain versions of the GNU* compilers on Linux* OS and Mac OS* X, as well as the Intel compiler version 10.*x* (and later).
- The Legacy OpenMP libraries, which provide compatibility with OpenMP support provided by Intel compilers, including Intel compilers prior to version 10.0.

To select the Compatibility (default) or Legacy OpenMP libraries, use the Intel compiler to link your application and specify the Intel compiler option `/Qopenmp-lib` (Windows OS) or `-openmp-lib` (Linux OS and Mac OS X) .

The term "object-level interoperability" refers to the ability to link object files and libraries generated by one compiler with object files and libraries generated by the second compiler, such that the resulting executable runs successfully. In contrast, "source compatibility" means that the entire application is compiled and linked by one compiler, and you do not need to modify the sources to get the resulting executable to run successfully.

Different compilers support different versions of the OpenMP specification. Based on the OpenMP features your application uses, determine what version of the OpenMP specification your application requires. If your application uses an OpenMP specification level equal or less than the OpenMP specification level supported by all the compilers, your application should have source compatibility with all compilers, but you need to link all object files and libraries with the same compiler's OpenMP libraries.

OpenMP Compatibility Libraries Provided by Intel Compilers

The Compatibility libraries provide source compatibility and object-level interoperability with the OpenMP support provided by:

- On Windows* OS, certain versions of Microsoft Visual C++* that support OpenMP, starting with Microsoft Visual C++ 2005.
- On Linux* OS and Mac OS* X, certain versions of GNU* `gcc`* that support OpenMP, starting with GNU* `gcc`* version 4.2.
- Intel compilers versions 10.0 and later and their supplied OpenMP libraries.

For Fortran applications on Linux systems, it is not possible to link objects compiled by the Intel® Fortran Compiler (`ifort`) with objects compiled by the GNU* Fortran compiler (`gfortran`). Thus, for mixed-language C++ and Fortran applications, you can do one of the following:

- Combine objects created by `gfortran` and Intel® C++ objects, if you specify the Intel OpenMP Compatibility libraries during linking.
- Combine objects created by the Intel C++ compiler and the Intel Fortran Compiler, using Intel OpenMP Compatibility or Legacy libraries.

OpenMP Legacy Libraries Provided by Intel Compilers

The set of Legacy OpenMP libraries has been provided by Intel compilers for multiple releases and provide source compatibility and object-level interoperability with the current Legacy libraries and OpenMP libraries provided by previous Intel compiler versions, including those prior to version 10.0. The Legacy libraries are not compatible with OpenMP support from non-Intel compilers, such as Microsoft Visual C++*, GNU `gcc`*, or GNU Fortran.

You should only use the Legacy libraries if your application requires object-level interoperability with OpenMP library versions provided prior to Intel compilers version 10.0.

Guidelines for Using Different Intel Compiler Versions

To avoid possible linking or run-time problems, follow these guidelines:

- If you compile your application using only the Intel compilers, avoid mixing the Compatibility and Legacy OpenMP runtime libraries. That is, you must link the entire application with either the Compatibility or Legacy libraries.
- When using the Legacy libraries, use the most recent Intel compiler to link the entire application. However, be aware that the Legacy libraries are deprecated, so for a future release, you will need to link the entire application with the Compatibility libraries.
- Use dynamic instead of static OpenMP libraries to avoid linking multiple copies of the libraries into a single program. For details, see OpenMP Support Libraries.

Guidelines for Using Intel and Non-Intel Compilers

To avoid possible linking or run-time problems, follow these guidelines:

- Always link the entire application using the Intel compiler OpenMP Compatibility libraries. This avoids linking multiple copies of the OpenMP runtime libraries from different compilers. It is easiest if you use the Intel compiler command (driver) to link the application, but it is possible to link with the Intel compiler OpenMP Compatibility libraries when linking the application using the GNU* or Visual C++ compiler (or linker) commands.
- If possible, compile all the OpenMP sources with the same compiler. If you compile (not link) using multiple compilers such as the Microsoft Visual C++* or GNU compilers that provide object-level interoperability with the Compatibility libraries, see the instructions in Using the OpenMP Compatibility Libraries.
- Use dynamic instead of static OpenMP libraries to avoid linking multiple copies of the libraries into a single program. For details, see OpenMP Support Libraries.

Limitations When Using OpenMP Compatibility Libraries with Other Compilers

Limitations of threadprivate objects on object-level interoperability:

- On Windows OS systems, the Microsoft Visual C++* compiler uses a different mechanism than the Intel compilers to reference threadprivate data. If you declare a variable as threadprivate in your code and you compile the code with both Intel compilers and Visual C++ compilers, the code compiled by the Intel compiler and the code compiled by the Visual C++* compiler will reference different locations for the variable even when referenced by the same thread. Thus, use the same compiler to compile all source modules that use the same threadprivate objects.
- On Linux OS systems, the GNU* compilers use a different mechanism than the Intel compilers to reference threadprivate data. If you declare a variable as threadprivate in your code and you compile the code with both Intel compilers and GNU compilers, the code compiled by the Intel compiler and the code compiled by the GNU compiler will reference different locations for the variable even when referenced by the same thread. Thus, use the same compiler to compile all source modules that use the same threadprivate objects.
- On Mac OS* X systems, the operating system does not currently support the mechanism used by the GNU* compiler to support threadprivate data. Threadprivate data objects will only be accessible by name from object files compiled by the Intel compilers.

Using OpenMP*

Using OpenMP* in your application requires several steps. To use OpenMP, you must do the following:

1. Add OpenMP directives to your application source code.
2. Compile the application with `-openmp` (Linux* and Mac OS* X) or `/Qopenmp` (Windows*) option.
3. For applications with large local or temporary arrays, you may need to increase the stack space available at run-time. In addition, you may need to increase the stack allocated to individual threads by using the KMP_STACKSIZE environment variable or by setting the corresponding library routines.

You can set other environment variables for the multi-threaded code execution.

Add OpenMP Support to the Application

Add the OpenMP API routine declarations to your application by adding a statement similar to the following in your code:

Example
`use omp_lib`

OpenMP Directive Syntax

OpenMP directives use a specific format and syntax. Intel Extension Routines to OpenMP* describes the OpenMP extensions to the specification that have been added to the Intel® compiler.

The following syntax illustrates using the directives in your source.

Example
`<prefix> <directive> [<clause>[[,]<clause>...]]`

where:

- <*prefix*> - Required for all OpenMP directives. For free form source input, the prefix is `!$OMP` only; for fixed form source input, the prefix is `!$OMP` or *`C$OMP`*.
- <*directive*> - A valid OpenMP directive. Must immediately follow the prefix; for example: `!$OMP PARALLEL`.
- [<*clause*>] - Optional. Clauses can be in any order and repeated as necessary, unless otherwise restricted.
- [<*newline*>] - A required component of directive syntax. It precedes the structured block which is enclosed by this directive.
- [,]: Optional. Commas between more than one <*clause*> are optional.

The directives are interpreted as comments if you omit the `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows*) option.

The OpenMP constructs defining a parallel region have one of the following syntax forms:

Example

`!$OMP <directive>`
`  <structured block of code>`
`!$OMP END <directive>`
`or`
`!$OMP <directive>`
`  <structured block of code>`
`or`
`!$OMP <directive>`

The following example demonstrates one way of using an OpenMP directive to parallelize a loop.

Example

```
subroutine simple_omp(a, N)
  use omp_lib
  integer :: N, a(N)
!$OMP PARALLEL DO
  do i = 1, N
    a(i) = i*2
  end do
end subroutine simple_omp
```

See OpenMP* Examples for more examples on using directives in specific circumstances.

Compile the Application

The `-openmp` (Linux* and Mac OS* X) or `/Qopenmp` (Windows*) option enables the parallelizer to generate multi-threaded code based on the OpenMP directives in the source. The code can be executed in parallel on single processor, multi-processor, or multi-core processor systems.

NOTE. IA-64 Architecture: Specifying this option implies `-opt-mem-bandwith1` (Linux) or `/Qopt-mem-bandwidth1` (Windows).

The `openmp` option works with both `-O0` (Linux and Mac OS X) and `/Od` (Windows) and with any optimization level of `-O1`, `-O2` and `-O3` (Linux and Mac OS X) or `/O1`, `/O2` and `/O3` (Windows).

Specifying `-O0` (Linux and Mac OS X) or `/Od` (Windows) with the OpenMP option helps to debug OpenMP applications.

Compile your application using commands similar to those shown below:

Operating System	Description
Linux and Mac OS X	`ifort -openmp source_file`
Windows	`ifort /Qopenmp source_file`

Assume that you compile the sample above, using the commands similar to the following, where `-c` (Linux and Mac OS X) or `/c` (Windows) instructs the compiler to compile the code without generating an executable:

Operating System	Example
Linux and Mac OS X	`ifort -openmp -c parallel.f90`
Windows	ifort /Qopenmp /c parallel.f90

The compiler might return a message similar to the following:

```
parallel.f90(20) : (col. 6) remark: OpenMP DEFINED LOOP WAS PARALLELIZED.
```

Configure the OpenMP Environment

Before you run the multi-threaded code, you can set the number of desired threads using the OpenMP environment variable, `OMP_NUM_THREADS`. See the OpenMP Environment Variables.

Parallel Processing Model

A program containing OpenMP* API compiler directives begins execution as a single thread, called the initial thread of execution. The initial thread executes sequentially until the first parallel construct is encountered.

In the OpenMP API, the `PARALLEL` and `END PARALLEL` directives define the extent of the parallel construct. When the initial thread encounters a parallel construct, it creates a team of threads, with the initial thread becoming the master of the team. All program statements enclosed by the parallel construct are executed in parallel by each thread in the team, including all routines called from within the enclosed statements.

The statements enclosed lexically within a construct define the static extent of the construct. The dynamic extent includes all statements encountered during the execution of a construct by a thread, including all called routines.

When a thread encounters the end of a structured block enclosed by a parallel construct, the thread waits until all threads in the team have arrived. When that happens the team is dissolved, and only the master thread continues execution of the code following the parallel construct. The other threads in the team enter a wait state until they are needed to form another team. You can specify any number of parallel constructs in a single program. As a result, thread teams can be created and dissolved many times during program execution.

The following example illustrates, from a high level, the execution model for the OpenMP constructs. The comments in the code explain the structure of each construct or section.

Example

```
PROGRAM MAIN           ! Begin serial execution.
  ...                  ! Only the initial thread executes.
 !$OMP PARALLEL        ! Begin a Parallel construct, form a team.
   ...                 ! This code is executed by each team member.
  !$OMP SECTIONS       ! Begin a worksharing construct.
    !$OMP SECTION      ! One unit of work.
     ...               !
    !$OMP SECTION      ! Another unit of work.
     ...               !
   !$OMP END SECTIONS  ! Wait until both units of work complete.
   ...                 ! More Replicated Code.
  !$OMP DO             ! Begin a worksharing construct,
     DO                ! each iteration is a unit of work.
     ...               ! Work is distributed among the team.
     END DO            !
  !$OMP END DO NOWAIT  ! End of worksharing construct, NOWAIT
                       ! is specified (threads need not wait).
                       ! This code is executed by each team member.
  !$OMP CRITICAL       ! Begin critical construct.
     ...               ! One thread executes at a time.
  !$OMP END CRITICAL   ! End the critical construct.
   ...                 ! This code is executed by each team member.
  !$OMP BARRIER        ! Wait for all team members to arrive.
   ...                 ! This code is executed by each team member.
 !$OMP END PARALLEL    ! End of parallel onstruct, disband team.
```

Example

```
                        ! and continue with serial execution.
  ...                   ! Possibly more parallel constructs.
END PROGRAM MAIN        ! End serial execution.
```

Using Orphaned Directives

In routines called from within parallel constructs, you can also use directives. Directives that are not in the static extent of the parallel construct, but are in the dynamic extent, are called orphaned directives. Orphaned directives allow you to execute portions of your program in parallel with only minimal changes to the sequential version of the program. Using this functionality, you can code parallel constructs at the top levels of your program call tree and use directives to control execution in any of the called routines. For example:

Example

```
subroutine F
...
!$OMP PARALLEL...
   call G
...
subroutine G
!$OMP DO... ! This is an orphaned directive.
...
```

This is an orphaned `DO` loop directive since the parallel region is not lexically present in `subroutine G`.

Data Environment Controls

You can control the data environment within parallel and worksharing constructs. Using directives and data environment clauses on directives, you can privatize named global-lifetime objects by using `THREADPRIVATE` directive, or control data scope attributes by using the data environment clauses for directives that support them.

The data scope attribute clauses are:

- DEFAULT
- PRIVATE
- FIRSTPRIVATE
- LASTPRIVATE
- REDUCTION
- SHARED

The data copying clauses are:

- COPYIN
- COPYPRIVATE

You can use several directive clauses to control the data scope attributes of variables for the duration of the construct in which you specify them; however, if you do not specify a data scope attribute clause on a directive, the behavior for the variable is determined by the default scoping rules, which are described in the OpenMP API specification, for the variables affected by the directive.

Determining How Many Threads to Use

For applications where the workload depends on application input that can vary widely, delay the decision about the number of threads to employ until runtime when the input sizes can be examined. Examples of workload input parameters that affect the thread count include things like matrix size, database size, image/video size and resolution, depth/breadth/bushiness of tree based structures, and size of list based structures. Similarly, for applications designed to run on systems where the processor count can vary widely, defer the number of threads to employ until application run-time when the machine size can be examined.

For applications where the amount of work is unpredictable from the input data, consider using a calibration step to understand the workload and system characteristics to aid in choosing an appropriate number of threads. If the calibration step is expensive, the calibration results can be made persistent by storing the results in a permanent place like the file system.

Avoid simultaneously using more threads than the number of processing units on the system. This situation causes the operating system to multiplex the processors and typically yields sub-optimal performance.

When developing a library as opposed to an entire application, provide a mechanism whereby the user of the library can conveniently select the number of threads used by the library, because it is possible that the user has higher-level parallelism that renders the parallelism in the library unnecessary or even disruptive.

Use the `NUM_THREADS` clause on parallel regions to control the number of threads employed and use the if clause on parallel regions to decide whether to employ multiple threads at all. The `OMP_SET_NUM_THREADS` routine can also be used, but it also affects parallel regions created by the calling thread. The `NUM_THREADS` clause is local in its effect, so it does not impact other parallel regions.

By default, the Intel OpenMP runtime lets you to create a large number of threads and active nested parallel regions. Use `OMP_GET_THREAD_LIMIT()` and `OMP_GET_MAX_ACTIVE_LEVELS()` to determine the limits. Developers should carefully consider their thread usage and nesting of parallelism to avoid overloading the system. The `OMP_THREADS_LIMIT` environment variable limits the number of OpenMP threads to use for the whole OpenMP program. The `OMP_MAX_ACTIVE_LEVELS` environment variable limits the number of active nested parallel regions.

Verifying OpenMP* Using Parallel Lint

To accelerate migration of sequential applications to parallel applications using OpenMP, parallel lint can be very helpful by reducing application development and debugging time. This topic explains how to use parallel lint to optimize your parallel application. Parallel lint performs static

global analysis of a program to diagnose existing and potential issues with parallelization. One of the advantages of parallel lint is that it makes its checks considering the whole stack of parallel regions and worksharing constructs, even when placed in different routines.

Example

```
1        parameter (N = 100)
2        real, dimension(N) :: x,y
3
4   !$OMP PARALLEL DEFAULT(SHARED)
5   !$OMP SECTIONS
6   !$OMP SECTION
7        do i = 1, N
8        call work(x, N, i)
9        call output(x, N)
10        end do
11   !$OMP SECTION
12        call work(y, N, N)
13        call output(y, N)
14   !$OMP END SECTIONS
15   !$OMP END PARALLEL
16       print *, x, y
17       end
18
19
20       subroutine work(x, N, i)
21         real, dimension(N) :: x
22         x(i) = i*10.0
23       end subroutine work
24
```

Example

```
25        subroutine output(x, N)
26        real, dimension(N) :: x
27  !$OMP SINGLE
28          print *, x
29  !$OMP END SINGLE
tst.f(27): error #12200: SINGLE directive is not allowed in
the dynamic extent of SECTIONS directive (file:tst.f line:5)
```

This makes parallel lint a powerful tool for diagnosing OpenMP directives in whole program context. Parallel lint also provides checks to debug errors connected with data dependencies and race conditions.

Example

```
1         parameter (N = 10)
2         integer i
3         integer, dimension(N) :: factorial
4
5         factorial(1) = 1
6   !$OMP PARALLEL DO
7         do i = 2, N
8             factorial(i) = i * factorial(i-1)
9         end do
10         print *, factorial
11         end
tst.f(8): warning #12246: flow data dependence from
(file:tst.f line:8) to (file:tst.f line:8), due to
"FACTORIAL" may lead to incorrect program execution in parallel mode
```

Basics of Compilation

To enable parallel lint analysis, pass the `/Qdiag-enable:sc-parallel[n]` (Windows), `-diag-enable sc-parallel[n]` (Linux and Mac OS) option to the compiler.

Parallel lint is available for IA-32 and Intel® 64 architectures only.

Parallel lint requires the OpenMP option, `/Qopenmp` (Windows) `-openmp` (Linux and Mac OS). This option forces the compiler to process OpenMP directives to make parallelization specifics available for parallel lint analysis. If parallel lint is used without OpenMP, the compiler issues the following error message:

```
command line error: parallel lint not called due to lack of OpenMP

parallelization option, please add option /Qopenmp when using parallel lint.
```

If you are using Microsoft Visual Studio*, you should create a separate build configuration devoted to parallel lint, since object and library files produced by parallel lint should not be used to build your product.

Basic Checks

Parallel lint provides a broad set of OpenMP checks which are useful both for beginners in parallel programming using OpenMP and for advanced parallel developers. See the Overview section of this manual.

The examples below highlight the most useful features of parallel lint.

Case 1: Nested Regions

An OpenMP program is much more difficult to debug if it has nested parallel regions. Various restrictions apply to nested parallel constructs. Parallel lint can check nested parallel statements even if they are located in different files.

In the example below, a worksharing construct may not be closely nested inside a WORKSHARING, CRITICAL, ORDERED, or MASTER construct.

Example

```
1        parameter (N = 10)
2        real, dimension(N,N) :: x, y, z
3        x = 1.0
4        y = 2.0
5  !$OMP PARALLEL DEFAULT(SHARED)
6  !$OMP MASTER
7        call work(x, y, z, N)
8  !$OMP END MASTER
9  !$OMP END PARALLEL
10        print *, z
11        end
12
13        subroutine work(x, y, z, N)
14        real, dimension(N,N) :: x, y, z
15  !$OMP DO
16        do i = 1, N
17          do j = 1, N
18            z(i,j) = x(i,j) + y(j,i)
19          end do
20        end do
21        end subroutine work
tst.f(15): error #12200: LOOP directive is not allowed in
the dynamic extent of MASTER directive (file:tst.f line:6)
```

Case 2: Data-Sharing Attribute Clauses

Parallelization of an existing serial application requires accurate placement of data sharing clauses. Parallel lint can help determine not only improper usage of sharing clauses but also lack of proper data sharing directives.

The example below demonstrates the OpenMP standard restriction: "If the LASTPRIVATE clause is used on a construct to which NOWAIT is also applied, then the original list item remains undefined until a barrier synchronization has been performed to ensure that the thread that executed the sequentially last iteration, or the lexically last SECTION construct, has stored that list item." [OpenMP standard]

Example

```
1        integer, parameter :: N=10
2        integer last, i
3        real, dimension(N) :: a, b, c
4        b = 10.0
5        c = 50.0
6  !$OMP PARALLEL SHARED(a, b, c, last)
7  !$OMP DO LASTPRIVATE(last)
8        do i = 1, N
9          a(i) = b(i) + c(i)
10          last = i
11        end do
12  !$OMP END DO NOWAIT
13  !$OMP SINGLE
14        call sub(last)
15  !$OMP END SINGLE
16  !$OMP END PARALLEL
17        end
18
19        subroutine sub(last)
20        integer last
21        print *, last
22        end subroutine sub
tst.f(14): error #12220: LASTPRIVATE variable "LAST" in NOWAIT
```

Example

```
work-sharing construct is used before barrier synchronization
```

The next example demonstrates OpenMP standard restriction: "Private pointers that become allocated during the execution of parallel region should be explicitly deallocated by the program prior to the end of parallel region to avoid memory leaks."

Example

```
1        integer :: OMP_GET_THREAD_NUM
2        integer, pointer :: ptr
3        integer, pointer :: a(:)
4
5        call OMP_SET_NUM_THREADS(2)
6        allocate(ptr)
7        allocate(a(2))
8        ptr = 5
9        print *, ptr
10  !$OMP PARALLEL PRIVATE(ptr) SHARED(a)
11        allocate(ptr)
12        ptr = 3
13  !$OMP CRITICAL
14        a(OMP_GET_THREAD_NUM()+1) = ptr
15  !$OMP END CRITICAL
16  !$OMP END PARALLEL
17        print *, a
18        end
as_44_1.f(11): error #12359: private pointer "PTR" should be explicitly deallocated by
the
program prior to the end of parallel region (file:as_44_1.f line:10) to avoid memory
leaks.
```

Case 3: Data Dependence

Data dependency issues are very difficult to debug in parallel programs due to non-deterministic behavior. Parallel lint is able to determine data dependency issues in programs without executing them.

To turn on data dependency analysis you should specify severity level 3 parallel lint in diagnostics.

Example

```
1        integer i, a(4)
2  !$OMP PARALLEL DO  SHARED(i) NUM_THREADS(4)
3        do i=1,4
4           a(i) = loc(i)
5        end do
6  !$OMP END PARALLEL DO
7        print *,a
8        end
tst.f(3): warning #12246: flow data dependence from
(file:tst.f line:3) to (file:tst.f line:3), due to "I"
may lead to incorrect program execution in parallel mode
```

Case 4: Treadprivate Variables

Example

```
1        integer a(1000)
2  !$OMP THREADPRIVATE(a)
3        integer i, sum
4
5  !$OMP PARALLEL DO
6        do i=1,1000
7           a(i) = i
8        end do
9  !$OMP END PARALLEL DO
10  !$OMP PARALLEL DO REDUCTION(+:sum)
11        do i=10,1000
12           sum = sum + a(i)
13        end do
14  !$OMP END PARALLEL DO
15        print *,sum
16        end
tst.f(12): error #12344: THREADPRIVATE variable "A"
is used in loops with different initial values. See
loops (file:tst.f line:6) and (file:tst.f line:11).
```

Case 5: Reductions

Reductions are widely used in parallel programming, but there are a lot of hidden and explicit restrictions. Parallel lint helps avoid potential problems connected to reductions. In this case explicit constraint from the OpenMP API, variables that appear in a `REDUCTION` clause must be `SHARED` in the enclosing context, is illustrated.

Example

```
1        integer i, j
2        real a
3
4  !$OMP PARALLEL PRIVATE(a)
5        do i = 1, 10
6        call sub(a,i)
7        end do
8  !$OMP SINGLE
9        print *, a
10  !$OMP END SINGLE
11  !$OMP END PARALLEL
12        end
13
14        subroutine sub(a,i)
15        integer i
16        real a
17  !$OMP DO REDUCTION(+: a)
18          do j = 1, 10
19              a = a + i + j
20          end do
21        end subroutine sub
as_35_1.f(17): error #12208: variable "A" must be SHARED in the enclosing
```

Example
`context since it is specified in a REDUCTION clause at (file:as_35_1.f line:4)`

OpenMP* Clauses”

Data Scope Attribute Clauses Overview

You can use several directive clauses to control the data scope attributes of variables for the duration of the construct in which you specify them. If you do not specify a data scope attribute clause on a directive, the default is `SHARED` for those variables affected by the directive.

Each of the data scope attribute clauses accepts a list, which is a comma-separated list of named variables or named common blocks that are accessible in the scoping unit. When you specify named common blocks, they must appear between slashes (/*name*/).

Not all of the clauses are allowed on all directives, but the directives to which each clause applies are listed in the clause descriptions.

The data scope attribute clauses are:

- `COPYIN`
- `DEFAULT`
- `PRIVATE`
- `FIRSTPRIVATE`
- `LASTPRIVATE`
- `REDUCTION`
- `SHARED`

Specifying Schedule Type and Chunk Size

The `SCHEDULE` clause of the `DO` or `PARALLEL DO` directive specifies a scheduling algorithm that determines how iterations of the `DO` loop are divided among and dispatched to the threads of the team. The `SCHEDULE` clause applies only to the current `DO` or `PARALLEL DO` directive.

Within the `SCHEDULE` clause, you must specify a *`schedule type`* and, optionally, a *`chunk size`*. A *`chunk`* is a contiguous group of iterations dispatched to a thread. Chunk size must be a scalar integer expression.

The following list describes the schedule types and how the chunk size affects scheduling:

Schedule Type	Description
STATIC	The iterations are divided into pieces having a size specified by chunk. The pieces are statically dispatched to threads in the team in a round-robin manner in the order of thread number. When chunk is not specified, the iterations are first divided into contiguous pieces by dividing the number of iterations by the number of threads in the team. Each piece is then dispatched to a thread before loop execution begins.
DYNAMIC	The iterations are divided into pieces having a size specified by chunk. As each thread finishes its currently dispatched piece of the iteration space, the next piece is dynamically dispatched to the thread. When no chunk is specified, the default is 1.
GUIDED	The chunk size is decreased exponentially with each succeeding dispatch. Chunk specifies the minimum number of iterations to dispatch each time. If there are less than chunk number of iterations remaining, the rest are dispatched. When no chunk is specified, the default is 1.
AUTO	When SCHEDULE(AUTO) is specified, the decision regarding scheduling is delegated to the compiler. The programmer gives the compiler the freedom to choose any possible mapping of iterations to threads in the team.
RUNTIME	The decision regarding scheduling is deferred until run time. The schedule type and chunk size can be chosen at run time by using the OMP_SCHEDULE environment variable. When you specify RUNTIME, you cannot specify a chunk size.

The following list shows which schedule type is used, in priority order:

1. The schedule type specified in the SCHEDULE clause of the current DO or PARALLEL DO directive.
2. If the schedule type for the current DO or PARALLEL DO directive is RUNTIME, the default value specified in the OMP_SCHEDULE environment variable.
3. The compiler default schedule type of STATIC.

The following list shows which chunk size is used, in priority order:

- The chunk size specified in the SCHEDULE clause of the current DO or PARALLEL DO directive.
- For STATIC schedule type, the loop iteration space is divided evenly (approximately) by the number of threads in the team.
- For RUNTIME schedule type, the value specified in the OMP_SCHEDULE environment variable.
- For DYNAMIC and GUIDED schedule types, the default value 1.

COPYIN Clause

Use the COPYIN clause on the PARALLEL, PARALLEL DO, and PARALLEL SECTIONS directives to copy the data in the master thread variable or common block to the thread private copies of the variables or common block. The copy occurs at the beginning of the parallel region. The COPYIN clause applies only to variables or common blocks that have been declared THREADPRIVATE.

You do not have to specify a whole common block to be copied in; you can specify named variables that appear in the THREADPRIVATE common block.

Example

```
INTEGER, SAVE:: X

!OMP THREADPRIVATE(X)

!OMP PARALLEL COPYIN(X)
```

In the following example, the common blocks BLK1 and FIELDS are specified as thread private, but only one of the variables in common block FIELDS is specified to be copied.

Example

```
COMMON /BLK1/ SCRATCH
COMMON /FIELDS/ XFIELD, YFIELD, ZFIELD
!$OMP THREADPRIVATE(/BLK1/, /FIELDS/)
!$OMP PARALLEL DEFAULT(PRIVATE),COPYIN(/BLK1/,ZFIELD)
```

DEFAULT Clause

Use the DEFAULT clause on the PARALLEL, PARALLEL DO, PARALLEL SECTIONS and TASK directives to specify a default data scope attribute for all variables within the lexical extent of a parallel region. Variables in THREADPRIVATE common blocks are not affected by this clause. You can specify only one DEFAULT clause on a directive. The default data scope attribute can be one of the following:

Attribute	Description
PRIVATE	Makes all named objects in the lexical extent of the parallel or task region private to a thread. The objects include common block variables, but exclude THREADPRIVATE variables.
FIRSTPRIVATE	Makes all named objects in the lexical extent of the parallel or task region private to a thread, and initialized from the original object. The objects include common block variables, but exclude THREADPRIVATE variables.
SHARED	Makes all named objects in the lexical extent of the parallel or task region shared among all the threads in the team.
NONE	Declares that there is no implicit default as to whether variables are PRIVATE, FIRSTPRIVATE, or SHARED. You must

Attribute	Description
	explicitly specify the scope attribute for each variable in the lexical extent of the parallel or task region.

If you do not specify the DEFAULT clause, the default is DEFAULT (SHARED). However, loop control variables are always PRIVATE by default.

You can exempt variables from the default data scope attribute by using other scope attribute clauses on the parallel region as shown in the following example:

Example

```
!$OMP PARALLEL DO DEFAULT(PRIVATE), FIRSTPRIVATE(I),SHARED(X),
!$OMP& SHARED(R) LASTPRIVATE(I)
```

PRIVATE, FIRSTPRIVATE, and LASTPRIVATE Clauses

PRIVATE

Use the PRIVATE clause on the PARALLEL, DO, SECTIONS, SINGLE, PARALLEL DO, and PARALLEL SECTIONS directives to declare variables to be private to each thread in the team.

The behavior of variables declared PRIVATE is as follows:

- A new object of the same type and size is declared once for each thread in the team, and the new object is no longer storage associated with the original object.
- All references to the original object in the lexical extent of the directive construct are replaced with references to the private object.
- Variables defined as PRIVATE are undefined for each thread on entering the construct, and the corresponding shared variable is undefined on exit from a parallel construct.
- Contents, allocation state, and association status of variables defined as PRIVATE are undefined when they are referenced outside the lexical extent, but inside the dynamic extent, of the construct unless they are passed as actual arguments to called routines.

In the following example, the values of *I* and *J* are undefined on exit from the parallel region:

Example

```
INTEGER I,J
I = 1
J = 2
!$OMP PARALLEL PRIVATE(I) FIRSTPRIVATE(J)
I = 3
J = J + 2
!$OMP END PARALLEL
PRINT *, I, J
```

FIRSTPRIVATE

Use the FIRSTPRIVATE clause on the PARALLEL, DO, SECTIONS, SINGLE, PARALLEL DO, and PARALLEL SECTIONS directives to provide a superset of the PRIVATE clause functionality.

In addition to the PRIVATE clause functionality, private copies of the variables are initialized from the original object existing before the parallel construct.

LASTPRIVATE

Use the LASTPRIVATE clause on the DO, SECTIONS, PARALLEL DO, and PARALLEL SECTIONS directives to provide a superset of the PRIVATE clause functionality.

When the LASTPRIVATE clause appears on a DO or PARALLEL DO directive, the thread that executes the sequentially last iteration updates the version of the object it had before the construct.

When the LASTPRIVATE clause appears on a SECTIONS or PARALLEL SECTIONS directive, the thread that executes the lexically last section updates the version of the object it had before the construct.

Sub-objects that are not assigned a value by the last iteration of the DO loop or the lexically last SECTION directive are undefined after the construct.

Correct execution sometimes depends on the value that the last iteration of a loop assigns to a variable. You must list all such variables as arguments to a LASTPRIVATE clause so that the values of the variables are the same as when the loop is executed sequentially. As shown in the following example, the value of I at the end of the parallel region is equal to *N*+1, as it would be with sequential execution.

Example

```
!$OMP PARALLEL
  !$OMP DO LASTPRIVATE(I
    DO I=1,N
      A(I) = B(I) + C(I)
    END DO
  !$OMP END PARALLEL
CALL REVERSE(I)
```

REDUCTION Clause

Use the REDUCTION clause on the PARALLEL, DO, SECTIONS, PARALLEL DO, and PARALLEL SECTIONS directives to perform a reduction on the specified variables by using an operator or intrinsic as shown:

Example

REDUCTION (operator or intrinsic: *list*)

where:

- Operator can be one of the following: +, *, –, .AND., .OR., .EQV., or .NEQV..
- Intrinsic can be one of the following: MAX, MIN, IAND, IOR, or IEOR.

The specified variables must be named variables of intrinsic type and must be shared in the enclosing context. Deferred-shape and assumed-size arrays are not allowed. A private copy of each specified variable is created for each thread as if you had used the PRIVATE clause. The private copy is initialized to a value that depends on the operator or intrinsic as shown in the following table. The actual initialization value is consistent with the data type of the reduction variable.

Operators/Intrinsics and Initialization Values for Reduction Variables

Operators/Intrinsic	Initialization Value
+	0
*	1
-	0
.AND.	.TRUE.
.OR.	.FALSE.
.EQV.	.TRUE.
.NEQV.	.FALSE.
MAX	Largest representable number
MIN	Smallest representable number
IAND	All bits on
IOR	0
IEOR	0

At the end of the construct to which the reduction applies, the shared variable is updated to reflect the result of combining the original value of the shared reduction variable with the final value of each of the private copies using the specified operator.

Except for subtraction, all of the reduction operators are associative and the compiler can freely reassociate the computation of the final value. The partial results of a subtraction reduction are added to form the final value.

The value of the shared variable becomes undefined when the first thread reaches the clause containing the reduction, and it remains undefined until the reduction computation is complete. Normally, the computation is complete at the end of the `REDUCTION` construct. However, if you use the `REDUCTION` clause on a construct to which `NOWAIT` is also applied, the shared variable remains undefined until a barrier synchronization has been performed. This ensures that all of the threads have completed the `REDUCTION` clause.

The REDUCTION clause is intended to be used on a region or worksharing construct in which the reduction variable is used only in reduction statements having one of the following forms:

Form	Description
x = x operator expr	x is a scalar variable of intrinsic type. Arrays are allowed.
x = expr operator x	except for subtraction
x = intrinsic (x, expr)	intrinsic is either MAX, MIN, IAND, IOR, or IEOR
x = intrinsic (expr, x)	operator is either +, *, –, /, .AND., .OR., .EQV., or .NEQV.

Some reductions can be expressed in other forms. For instance, a MAX reduction might be expressed as follows:

Example
IF (x .LT. expr) x = expr

Alternatively, the reduction might be hidden inside a subroutine call. Be careful that the operator specified in the REDUCTION clause matches the reduction operation.

Any number of reduction clauses can be specified on the directive, but a variable can appear only once in a REDUCTION clause for that directive as shown in the following example:

Example
!$OMP DO REDUCTION(+: A, Y),REDUCTION(.OR.: AM)

The following example shows how to use the REDUCTION clause:

Example

```
!$OMP PARALLEL DO DEFAULT(PRIVATE),SHARED(A,B),REDUCTION(+: A,B)
  DO I=1,N
  CALL WORK(ALOCAL,BLOCAL)
  A = A + ALOCAL
  B = B + BLOCAL
  END DO
!$OMP END PARALLEL DO
```

SHARED Clause

Use the SHARED clause on the PARALLEL, PARALLEL DO, and PARALLEL SECTIONS directives to make variables shared among all the threads in a team.

In the following example, the variables *X* and *NPOINTS* are shared among all the threads in the team:

Example

```
!$OMP PARALLEL DEFAULT(PRIVATE),SHARED(X,NPOINTS)
  IAM = OMP_GET_THREAD_NUM()
  NP = OMP_GET_NUM_THREADS()
  IPOINTS = NPOINTS/NP
  CALL SUBDOMAIN(X,IAM,IPOINTS)
!$OMP END PARALLEL
```

OpenMP* Directives

Programming with OpenMP*

The Intel® compiler accepts a Fortran program containing OpenMP* directives as input and produces a multithreaded version of the code. When the parallel program begins execution, a single thread exists. This thread is called the initial thread.

The initial thread can become the master thread, of a team, when it encounters a parallel region. The initial thread will continue to process serially until it encounters a parallel region.

Parallel Region

A parallel region is a block of code that must be executed by a team of threads in parallel. In the OpenMP API, a parallel construct is defined by placing OpenMP directive `PARALLEL` at the beginning and directive `END PARALLEL` at the end of the code segment. Code segments thus bounded can be executed in parallel.

A structured block of code is a collection of one or more executable statements with a single point of entry at the top and a single point of exit at the bottom.

The compiler supports worksharing and synchronization constructs. Each of these constructs consists of one or two specific OpenMP directives and sometimes the enclosed or following structured block of code.

At the end of the parallel region, threads wait until all team members have arrived. The team is logically disbanded (but may be reused in the next parallel region), and the master thread continues serial execution until it encounters the next parallel region.

Worksharing Construct

A worksharing construct divides the execution of the enclosed code region among the members of the team created on entering the enclosing parallel region. When the master thread enters a parallel region, a team of threads is formed. Starting from the beginning of the parallel region, code is executed by all team members until a worksharing construct is encountered. A worksharing construct divides the execution of the enclosed code among the members of the team that encounter it.

The OpenMP `SECTIONS` or `DO` constructs are defined as worksharing constructs because they distribute the enclosed work among the threads of the current team. A worksharing construct is only distributed if it is encountered during dynamic execution of a parallel region. If the

worksharing construct occurs lexically inside of the parallel region, then it is always executed by distributing the work among the team members. If the worksharing construct is not lexically (explicitly) enclosed by a parallel region (that is, it is orphaned), then the worksharing construct will be distributed among the team members of the closest dynamically-enclosing parallel region, if one exists. Otherwise, it will be executed serially.

When a thread reaches the end of a worksharing construct, it may wait until all team members within that construct have completed their work. When all of the work defined by the worksharing construct is finished, the team exits the worksharing construct and continues executing the code that follows.

A combined parallel/worksharing construct denotes a parallel region that contains only one worksharing construct.

Parallel Processing Directive Groups

The parallel processing directives include the following groups:

Parallel Region Directives

- `PARALLEL` and `END PARALLEL`

Worksharing Construct Directives

- The `DO` and `END DO` directives specify parallel execution of loop iterations.
- The `SECTIONS` and `END SECTIONS` directives specify parallel execution for arbitrary blocks of sequential code. Each `SECTION` is executed once by a thread in the team.
- The `SINGLE` and `END SINGLE` directives define a section of code where exactly one thread is allowed to execute the code; threads not chosen to execute this section ignore the code.

Combined Parallel/Worksharing Construct Directives

The combined parallel/worksharing constructs provide an abbreviated way to specify a parallel region that contains a single worksharing construct. The combined parallel/worksharing constructs are:

- `PARALLEL DO` and `END PARALLEL DO`
- `PARALLEL SECTIONS` and `END PARALLEL SECTIONS`
- `WORKSHARE` and `PARALLEL WORKSHARE`

Synchronization and MASTER Directives

Synchronization is the interthread communication that ensures the consistency of shared data and coordinates parallel execution among threads. Shared data is consistent within a team of threads when all threads obtain the identical value when the data is accessed. A synchronization construct is used to insure this consistency of the shared data.

The OpenMP synchronization directives are CRITICAL, ORDERED, ATOMIC, FLUSH, and BARRIER.

Directive	Usage
CRITICAL	Within a parallel region or a worksharing construct only one thread at a time is allowed to execute the code within a CRITICAL construct.
ORDERED	Used in conjunction with a DO or SECTIONS construct to impose a serial order on the execution of a section of code.
ATOMIC	Used to update a memory location in an uninterruptable fashion.
FLUSH	Used to insure that all threads in a team have a consistent view of memory.
BARRIER	Forces all team members to gather at a particular point in code. Each team member that executes a BARRIER waits at the BARRIER until all of the team members have arrived. A BARRIER cannot be used within worksharing or other synchronization constructs due to the potential for deadlock.
MASTER	The directive is used to force execution by the master thread.

See the list of OpenMP Directives and Clauses.

Data Sharing

Data sharing is specified at the start of a parallel region or worksharing construct by using the `SHARED` and `PRIVATE` clauses. All variables in the `SHARED` clause are shared among the members of a team. The application must do the following:

- Synchronize access to these variables.
- Insure that all variables in the `PRIVATE` clause are private to each team member. For the entire parallel region, assuming `t` team members, there are `t+1` copies of all the variables in the PRIVATE clause: one global copy that is active outside parallel regions and a `PRIVATE` copy for each team member.
- Initialize `PRIVATE` variables at the start of a parallel region, unless the `FIRSTPRIVATE` clause is specified. In this case, the `PRIVATE` copy is initialized from the global copy at the start of the construct at which the `FIRSTPRIVATE` clause is specified.
- Update the global copy of a `PRIVATE` variable at the end of a parallel region. However, the `LASTPRIVATE` clause of a `DO` directive enables updating the global copy from the team member that executed serially the last iteration of the loop.

In addition to `SHARED` and `PRIVATE` variables, individual variables and entire common blocks can be privatized using the `THREADPRIVATE` directive.

Orphaned Directives

OpenMP contains a feature called orphaning that dramatically increases the expressiveness of parallel directives. Orphaning is a situation when directives related to a parallel region are not required to occur lexically within a single program unit. Directives such as `CRITICAL`, `BARRIER`, `SECTIONS`, `SINGLE`, `MASTER`, `DO`, and `TASK` can occur by themselves in a program unit, dynamically "binding" to the enclosing parallel region at run time.

Orphaned directives enable parallelism to be inserted into existing code with a minimum of code restructuring. Orphaning can also improve performance by enabling a single parallel region to bind with multiple DO directives located within called subroutines. Consider the following code segment:

Example

```
subroutine phase1
  integer :: i
  !$OMP DO PRIVATE(i) SHARED(n)
  do i = 1, 200
    call some_work(i)
  end do
  !$OMP END DO
end
subroutine phase2
  integer :: j
  !$OMP DO PRIVATE(j) SHARED(n)
  do j = 1, 100
    call more_work(j)
  end do
  !$OMP END DO
end
program par
  !$OMP PARALLEL
  call phase1
  call phase2
  !$OMP END PARALLEL
end program par
```

Orphaned Directives Usage Rules

The following orphaned directives usage rules apply:

- Any collective operation (worksharing construct or `BARRIER`) executed inside of a worksharing construct is illegal.
- It is illegal to execute a collective operation (worksharing construct or `BARRIER`) from within a synchronization region (`CRITICAL`/`ORDERED`).
- The opening and closing directives of a directive pair (for example, `DO` and `END DO`) must occur in a single block of the program.
- Private scoping of a variable can be specified at a worksharing construct. Shared scoping must be specified at the parallel region.

Preparing Code for OpenMP Processing

The following are the major stages and steps of preparing your code for using OpenMP. Typically, the first two stages can be done on uniprocessor or multiprocessor systems; later stages are typically done on dual core processor and multiprocessor systems.

Before Inserting OpenMP Directives

Before inserting any OpenMP parallel directives, verify that your code is safe for parallel execution by doing the following:

- Place local variables on the stack. This is the default behavior of the Intel Compiler when `-openmp` (Linux* and Mac OS* X) or `/Qopenmp` (Windows*) is specified.
- Use `-automatic` or `-auto-scalar` (Linux and Mac OS X) or `/automatic` (Windows) to make the locals automatic. This is the default behavior of the Intel® compiler when the `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows) compiler option is specified. Avoid using the `-save` (Linux and Mac OS X) or `/Qsave` (Windows) option, which inhibits stack allocation of local variables. By default, automatic local variables become shared across threads, so you may need to add synchronization code to ensure proper access by threads.

Analyze

The analysis includes the following major actions:

1. Profile the program to find out where it spends most of its time. This is the part of the program that benefits most from parallelization efforts. This stage can be accomplished using basic PGO options.
2. Wherever the program contains nested loops, choose the outer-most loop, which has very few cross-iteration dependencies.

Restructure

To restructure your program for successful OpenMP implementation, you can perform some or all of the following actions:

- If a chosen loop is able to execute iterations in parallel, introduce a `PARALLEL DO` construct around this loop.
- Try to remove any cross-iteration dependencies by rewriting the algorithm.
- Synchronize the remaining cross-iteration dependencies by placing `CRITICAL` constructs around the uses and assignments to variables involved in the dependencies.
- List the variables that are present in the loop within appropriate `SHARED`, `PRIVATE`, `LASTPRIVATE`, `FIRSTPRIVATE`, or `REDUCTION` clauses.
- List the `DO` index of the parallel loop as `PRIVATE`. This step is optional.
- `COMMON` block elements must not be placed on the `PRIVATE` list if their global scope is to be preserved. The `THREADPRIVATE` directive can be used to privatize to each thread the `COMMON` block containing those variables with global scope. `THREADPRIVATE` creates a copy of the `COMMON` block for each of the threads in the team.
- Any I/O in the parallel region should be synchronized.
- Identify more parallel loops and restructure them.
- If possible, merge adjacent `PARALLEL DO` constructs into a single parallel region containing multiple `DO` directives to reduce execution overhead.

Tune

The tuning process should include minimizing the sequential code in critical sections and load balancing by using the `SCHEDULE` clause or the `OMP_SCHEDULE` environment variable.

NOTE. This step is typically performed on dual core processor and multiprocessor systems.

Combined Parallel and Worksharing Constructs

The combined parallel/worksharing constructs provide an abbreviated way to specify a parallel region that contains a single worksharing construct. The combined parallel/worksharing constructs are:

- `PARALLEL DO` and `END PARALLEL DO`
- `PARALLEL SECTIONS` and `END PARALLEL SECTIONS`
- `PARALLEL WORKSHARE` and `END PARALLEL WORKSHARE`

For more details on these directives, see OpenMP* Fortran Compiler Directives.

PARALLEL DO and END PARALLEL DO

Use the `PARALLEL DO` directive to specify a parallel region that implicitly contains a single `DO` directive. You can specify one or more of the clauses for the `PARALLEL DO` directives.

The following example shows how to parallelize a simple loop. The loop iteration variable is private by default, so it is not necessary to declare it explicitly. The `END PARALLEL DO` directive is optional:

Example

```
subroutine par(a, b, N)
  integer :: i, N, a(N), b(N)
  !$OMP PARALLEL DO
  do i= 1, N
    b(i) = (a(i) + a(i-1)) / 2.0
  end do
  !$OMP END PARALLEL DO
end subroutine par
```

PARALLEL SECTIONS and END PARALLEL SECTIONS

Use the `PARALLEL SECTIONS` directive to specify a parallel region that implicitly contains a single `SECTIONS` directive. You can specify one or more of the clauses for the `PARALLEL SECTIONS` directives.

The last section ends at the `END PARALLEL SECTIONS` directive.

In the following example, subroutines `X_AXIS`, `Y_AXIS`, and `Z_AXIS` can be executed concurrently. The first `SECTION` directive is optional. Note that all `SECTION` directives must appear in the lexical extent of the `PARALLEL SECTIONS`/`END PARALLEL SECTIONS` construct:

Example

```
!$OMP PARALLEL SECTIONS
!$OMP SECTION
      CALL X_AXIS
!$OMP SECTION
      CALL Y_AXIS
!$OMP SECTION
      CALL Z_AXIS
!$OMP END PARALLEL SECTIONS
```

PARALLEL WORKSHARE and END PARALLEL WORKSHARE

Use the `WORKSHARE` directive to divide work within blocks of worksharing statements or constructs into different units. This directive distributes the work of executing the units to threads of the team so each unit is only executed once.

Use the `PARALLEL WORKSHARE` directive to specify parallel regions, in an abbreviated way, that contain a single `WORKSHARE` directive.

When using either directive, be aware that your code cannot branch in to or out of the block defined by these directives.

Parallel Region Directives

The `PARALLEL` and `END PARALLEL` directives define a parallel region as follows:

Example

```
!$OMP PARALLEL
  ! parallel region
!$OMP END PARALLEL
```

When a thread encounters a parallel region, it creates a team of threads and becomes the master of the team. You can control the number of threads in a team by the use of an environment variable, run-time library call, or using the NUM_THREADS clause, or by combining these means.

Clauses Used

The PARALLEL directive takes an optional comma-separated list of clauses that specify as follows:

- IF: whether the statements in the parallel region are executed in parallel by a team of threads or serially by a single thread.
- NUM_THREADS: number of threads in a team.
- PRIVATE, FIRSTPRIVATE, SHARED, or REDUCTION: variable types
- DEFAULT: variable data scope attribute
- COPYIN: master thread common block values are copied to THREADPRIVATE copies of the common block

Changing the Number of Threads

Once created, the number of threads in the team remains constant for the duration of that parallel region. To explicitly change the number of threads used in the next parallel region, you can call the NUM_THREADS clause, call the OMP_SET_NUM_THREADS run-time library routine from a serial portion of the program, or use the OMP_NUM_THREADS environment variable. The order of precedence, or priority, is NUM_THREADS clause, OMP_SET_NUM_THREADS run-time library routine, then OMP_NUM_THREADS environment variable. For example, calling the NUM_THREADS clause overrides the OMP_SET_NUM_THREADS routine, and so forth.

Assuming you have used the OMP_NUM_THREADS environment variable to set the number of threads to 6, you can change the number of threads between parallel regions as follows:

Example

```
!$OMP PARALLEL
... ! This region is executed by 6 threads.
!$OMP END PARALLEL
CALL OMP_SET_NUM_THREADS(3)
!$OMP PARALLEL
... ! This region is executed by 3 threads.
!$OMP PARALLEL
!$OMP PARALLEL NUM_THREADS(4)
... ! This region is executed by 4 threads.
!$OMP END PARALLEL
```

Setting Units of Work

Use the worksharing directives such as DO, SECTIONS, and SINGLE to divide the statements in the parallel region into units of work and to distribute those units so that each unit is executed by one thread.

In the following example, the !$OMP DO and !$OMP END DO directives and all the statements enclosed by them comprise the static extent of the parallel region:

Example

```
!$OMP PARALLEL
  !$OMP DO
    DO I=1,N
      B(I) = (A(I) + A(I-1))/ 2.0
    END DO
  !$OMP END DO
!$OMP END PARALLEL
```

In the following example, the DO and END DO directives and all the statements enclosed by them, including all statements contained in the WORK subroutine, comprise the dynamic extent of the parallel region:

Example

```
!$OMP PARALLEL DEFAULT(SHARED)
  !$OMP DO
    DO I=1,N
      CALL WORK(I,N)
    END DO
  !$OMP END DO
!$OMP END PARALLEL
```

Setting Conditional Parallel Region Execution

When an IF clause is present on the PARALLEL directive, the enclosed code region is executed in parallel only if the scalar logical expression evaluates to .TRUE.. Otherwise, the parallel region is serialized. When there is no IF clause, the region is executed in parallel by default.

In the following example, the statements enclosed within the DO and END DO directives are executed in parallel only if there are more than three processors available. Otherwise the statements are executed serially:

Example

```
!$OMP PARALLEL IF (OMP_GET_NUM_PROCS() .GT. 3)
  !$OMP DO
    DO I=1,N
      Y(I) = SQRT(Z(I))
    END DO
  !$OMP END DO
!$OMP END PARALLEL
```

If a thread executing a parallel region encounters another parallel region, it creates a new team and becomes the master of that new team. By default, nested parallel regions are always executed by a team of one thread.

NOTE. To achieve better performance than sequential execution, a parallel region must contain one or more worksharing constructs so that the team of threads can execute work in parallel. It is the contained worksharing constructs that lead to the performance enhancements offered by parallel processing.

For more details on this directive, see OpenMP* Fortran Compiler Directives.

Synchronization Constructs

Synchronization constructs are used to ensure the consistency of shared data and to coordinate parallel execution among threads.

The synchronization constructs are:

- `ATOMIC` directive
- `BARRIER` directive
- `CRITICAL` directive
- `FLUSH` directive
- `MASTER` directive
- `ORDERED` directive

For more details on these directives, see OpenMP* Fortran Compiler Directives.

ATOMIC Directive

Use the `ATOMIC` directive to ensure that a specific memory location is updated atomically instead of exposing the location to the possibility of multiple, simultaneously writing threads.

This directive applies only to the immediately following statement, which must have one of the following forms:

Form	Description
`x = x operator expr`	*x* is a scalar variable of intrinsic type

Form	Description
`x = expr operator x`	*expr* is a scalar expression that does not reference `x`
`x = intrinsic (x, expr)`	*intrinsic* is either MAX, MIN, IAND, IOR or IEOR
`x = intrinsic (expr, x)`	`operator` is either `+`, `*`, `-`, `/`, `.AND.`, `.OR.`, `.EQV.`, or `.NEQV.`

This directive permits optimization beyond that of a critical section around the assignment. An implementation can replace all `ATOMIC` directives by enclosing the statement in a critical section. All of these critical sections must use the same unique name.

Only the load and store of *x* are atomic; the evaluation of `expr` is not atomic. To avoid race conditions, all updates of the location in parallel must be protected by using the `ATOMIC` directive, except those that are known to be free of race conditions. The function *intrinsic*, the operator *operator*, and the assignment must be the intrinsic function, operator, and assignment.

This restriction applies to the `ATOMIC` directive: All references to storage location *x* must have the same type parameters.

In the following example, the collection of `Y` locations is updated atomically:

Example

```
!$OMP ATOMIC
  Y = Y + B(I)
```

BARRIER Directive

To synchronize all threads within a parallel region, use the `BARRIER` directive. You can use this directive only within a parallel region defined by using the `PARALLEL` directive. You cannot use the `BARRIER` directive within the `DO`, `PARALLEL DO`, `SECTIONS`, `PARALLEL SECTIONS`, and `SINGLE` constructs.

When encountered, each thread waits at the `BARRIER` directive until all threads have reached the directive.

In the following example, the BARRIER directive ensures that all threads have executed the first loop and that it is safe to execute the second loop:

Example

```
!$OMP PARALLEL
  !$OMP DO PRIVATE(i)
    DO i = 1, 100
      b(i) = i
    END DO
  !$OMP BARRIER
  !$OMP DO PRIVATE(i)
    DO i = 1, 100
      a(i) = b(101-i)
    END DO
!$OMP END PARALLEL
```

CRITICAL and END CRITICAL

Use the CRITICAL and END CRITICAL directives to restrict access to a block of code, referred to as a critical section, to one thread at a time.

A thread waits at the beginning of a critical section until no other thread in the team is executing a critical section having the same name.

When a thread enters the critical section, a latch variable is set to closed and all other threads are locked out. When the thread exits the critical section at the END CRITICAL directive, the latch variable is set to open, allowing another thread access to the critical section.

If you specify a critical section name in the CRITICAL directive, you must specify the same name in the END CRITICAL directive. If you do not specify a name for the CRITICAL directive, you cannot specify a name for the END CRITICAL directive.

All unnamed CRITICAL directives map to the same name. Critical section names are global to the program.

The following example includes several CRITICAL directives, and illustrates a queuing model in which a task is dequeued and worked on. To guard against multiple threads dequeuing the same task, the dequeuing operation must be in a critical section. Because there are two independent queues in this example, each queue is protected by CRITICAL directives having different names, X_AXIS and Y_AXIS, respectively:

Example

```
!$OMP PARALLEL DEFAULT(PRIVATE),SHARED(X,Y)
  !$OMP CRITICAL(X_AXIS)
   CALL DEQUEUE(IX_NEXT, X)
  !$OMP END CRITICAL(X_AXIS)
    CALL WORK(IX_NEXT, X)
  !$OMP CRITICAL(Y_AXIS)
    CALL DEQUEUE(IY_NEXT,Y)
  !$OMP END CRITICAL(Y_AXIS)
  CALL WORK(IY_NEXT, Y)
!$OMP END PARALLEL
```

FLUSH Directive

Use the FLUSH directive to identify a synchronization point at which a consistent view of memory is provided. Thread-visible variables are written back to memory at this point.

To avoid flushing all thread-visible variables at this point, include a list of comma-separated named variables to be flushed. The following example uses the FLUSH directive for point-to-point synchronization between thread 0 and thread 1 for the variable ISYNC:

Example

```
!$OMP PARALLEL DEFAULT(PRIVATE),SHARED(ISYNC)
  IAM = OMP_GET_THREAD_NUM()
  ISYNC(IAM) = 0
  !$OMP BARRIER
  CALL WORK()
  ! Synchronize With My Neighbor
  ISYNC(IAM) = 1
  !$OMP FLUSH(ISYNC)
  ! Wait Till Neighbor Is Done
  DO WHILE (ISYNC(NEIGH) .EQ. 0)
  !$OMP FLUSH(ISYNC)
  END DO
. . .
!$OMP END PARALLEL
```

MASTER and END MASTER

Use the MASTER and END MASTER directives to identify a block of code that is executed only by the master thread.

The other threads of the team skip the code and continue execution. There is no implied barrier at the `END MASTER` directive. In the following example, only the master thread executes the routines `OUTPUT` and `INPUT`:

Example

```
!$OMP PARALLEL DEFAULT(SHARED)
  CALL WORK(X)
  !$OMP MASTER
    CALL OUTPUT(X)
    CALL INPUT(Y)
  !$OMP END MASTER
  CALL WORK(Y)
!$OMP END PARALLEL
```

ORDERED and END ORDERED

Use the `ORDERED` and `END ORDERED` directives within a `DO` construct to allow work within an ordered section to execute sequentially while allowing work outside the section to execute in parallel.

When you use the `ORDERED` directive, you must also specify the `ORDERED` clause on the `DO` directive.

Only one thread at a time is allowed to enter the ordered section, and then only in the order of loop iterations. In the following example, the code prints out the indexes in sequential order:

Example

```
!$OMP DO ORDERED,SCHEDULE(DYNAMIC)
  DO I=LB,UB,ST
    CALL WORK(I)
  END DO
SUBROUTINE WORK(K)
  !$OMP ORDERED
    WRITE(*,*) K
  !$OMP END ORDERED
END
```

THREADPRIVATEthreadprivate Directive

You can make named common blocks private to a thread, but global within the thread, by using the `THREADPRIVATE` directive.

Each thread gets its own copy of the common block with the result that data written to the common block by one thread is not directly visible to other threads. During serial portions and master sections of the program, accesses are to the master thread copy of the common block.

You cannot use a thread private variable in any clause other than the following:

- `COPYIN`
- `COPYPRIVATE`
- `SCHEDULE`
- `NUM_THREADS`
- `IF`

In the following example common blocks BLK1 and FIELDS are specified as thread private:

Example

```
COMMON /BLK1/ SCRATCH
COMMON /FIELDS/ XFIELD, YFIELD, ZFIELD
!$OMP THREADPRIVATE(/BLK1/,/FIELDS/)
```

For more details on this directive, see OpenMP* Fortran Compiler Directives.

Worksharing Construct Directives

A worksharing construct must be enclosed dynamically within a parallel region if the worksharing directive is to execute in parallel. No new threads are launched and there is no implied barrier on entry to a worksharing construct.

The worksharing constructs are:

- DO and END DO directives
- SECTIONS, SECTION, and END SECTIONS directives
- SINGLE and END SINGLE directives

For more details on these directives, see OpenMP* Fortran Compiler Directives.

DO and END DO

The DO directive specifies that the iterations of the immediately following DO loop must be dispatched across the team of threads so that each iteration is executed by a single thread. The loop that follows a DO directive cannot be a DO WHILE or a DO loop that does not have loop control. The iterations of the DO loop are dispatched among the existing team of threads.

The DO directive optionally lets you:

- Control data scope attributes
- Use the SCHEDULE clause to specify schedule type and chunk size (see Specifying Schedule Type and Chunk Size)

Clauses Used

The clauses for DO directive specify:

- Whether variables are PRIVATE, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION
- How loop iterations are scheduled onto threads
  - In addition, the ORDERED clause must be specified if the ORDERED directive appears in the dynamic extent of the DO directive.
  - If you do not specify the optional NOWAIT clause on the END DO directive, threads synchronize at the END DO directive. If you specify NOWAIT, threads do not synchronize, and threads that finish early proceed directly to the instructions following the END DO directive.

Usage Rules

- You cannot use a GOTO statement, or any other statement, to transfer control onto or out of the DO construct.
- If you specify the optional END DO directive, it must appear immediately after the end of the DO loop. If you do not specify the END DO directive, an END DO directive is assumed at the end of the DO loop, and threads synchronize at that point.
- The loop iteration variable is private by default, so it is not necessary to declare it explicitly.

SECTIONS, SECTION and END SECTIONS

Use the noniterative worksharing SECTIONS directive to divide the enclosed sections of code among the team. Each section is executed just one time by one thread.

Each section should be preceded with a SECTION directive, except for the first section, in which the SECTION directive is optional. The SECTION directive must appear within the lexical extent of the SECTIONS and END SECTIONS directives.

The last section ends at the END SECTIONS directive. When a thread completes its section and there are no undispatched sections, it waits at the END SECTION directive unless you specify NOWAIT.

The SECTIONS directive takes an optional comma-separated list of clauses that specifies which variables are PRIVATE, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION.

The following example shows how to use the SECTIONS and SECTION directives to execute subroutines X_AXIS, Y_AXIS, and Z_AXIS in parallel. The first SECTIONS directive is optional:

Example

```
!$OMP PARALLEL
  !$OMP SECTIONS
    !$OMP SECTION
      CALL X_AXIS
    !$OMP SECTION
      CALL Y_AXIS
    !$OMP SECTION
      CALL Z_AXIS
  !$OMP END SECTIONS
!$OMP END PARALLEL
```

SINGLE and END SINGLE

Use the SINGLE and END SINGLE directives when you want just one thread of the team to execute the enclosed block of code.

Threads that are not executing the SINGLE construct wait at the END SINGLE directive unless you specify NOWAIT.

The SINGLE directive takes an optional comma-separated list of clauses that specifies which variables are PRIVATE or FIRSTPRIVATE.

When the END SINGLE directive is encountered, an implicit barrier is erected and threads wait until all threads have finished. This can be overridden by using the NOWAIT option.

In the following example, the first thread that encounters the SINGLE directive executes subroutines OUTPUT and INPUT:

Example

```
!$OMP PARALLEL DEFAULT(SHARED)
  CALL WORK(X)
  !$OMP BARRIER
  !$OMP SINGLE
    CALL OUTPUT(X)
    CALL INPUT(Y)
  !$OMP END SINGLE
  CALL WORK(Y)
!$OMP END PARALLEL
```

Tasking Directives

The tasking model implemented by the Intel® compiler enables OpenMP* to parallelize a large range of applications. The directives used for tasking are:

- TASK and END TASK
- TASKWAIT

TASK and END TASK

The TASK and END TASK directives define an explicit task region as follows:

Example

```
!$OMP TASK
  ! explicit task region
!$OMP END TASK
```

The binding thread set of the task region is the current parallel team. A task region binds to the innermost enclosing PARALLEL region. When a thread encounters a task construct, a task is generated from the structured block enclosed in the construct. The encountering thread may

immediately execute the task, or defer its execution. A task construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

Clauses Used

The `TASK` directive takes an optional comma-separated list of clauses. The data environment of the task is created according to the data-sharing attribute clauses on the task construct and any defaults that apply. These clauses are:

- `IF`: whether the task has to be executed immediately or can be deferred.
- `UNTIED`: whether any thread in the team may resume a suspended task
- `PRIVATE`, `FIRSTPRIVATE`, or `SHARED: variable types`
- `DEFAULT`: variable data scope attribute

This example shows a way to generate N tasks with one thread and execute them with the threads in the parallel team:

Example

```
!$OMP PARALLEL SHARED(DATA)
  !$OMP SINGLE PRIVATE (I)
    DO I = 1, N
      !$OMP TASK FIRSTPRIVATE(I), SHARED(DATA)
        CALL WORK(DATA(I))
      !$OMP END TASK
    END DO
  !$OMP END SINGLE
!$OMP END PARALLEL
```

OpenMP* Advanced Issues

This topic discusses how to use the OpenMP* library functions and environment variables and discusses some guidelines for enhancing performance with OpenMP*.

OpenMP* provides specific function calls, and environment variables. See the following topics to refresh you memory about the primary functions and environment variable used in this topic:

- OpenMP* Run-time Library Routines
- OpenMP* Environment Variables

To use the function calls, include the `omp_lib.h` header file or specify `use omp_lib` to use the module file, which are installed in the `INCLUDE` directory during the compiler installation, and compile the application using the `-openmp` (Linux* and Mac OS* X) or `/Qopenmp` (Windows*) option.

The following example, which demonstrates how to use the OpenMP* functions to print the alphabet, also illustrates several important concepts.

First, when using functions instead of directives, your code must be rewritten; rewrites can mean extra debugging, testing, and maintenance efforts.

Second, it becomes difficult to compile without OpenMP support.

Third, it is very easy to introduce simple bugs, as in the loop (below) that fails to print all the letters of the alphabet when the number of threads is not a multiple of 26.

Fourth, you lose the ability to adjust loop scheduling without creating your own work-queue algorithm, which is a lot of extra effort. You are limited by your own scheduling, which is mostly likely static scheduling as shown in the example.

Example

```
include "omp_lib.h"
integer i
integer LettersPerThread, ThisThreadNum, StartLetter, EndLetter
call omp_set_num_threads(4)
  !$OMP PARALLEL PRIVATE(i)
    ! OMP_NUM_THREADS is not a multiple of 26,
    ! which can be considered a bug in this code.
    LettersPerThread = 26 / omp_get_num_threads()
    ThisThreadNum = omp_get_thread_num()
    StartLetter = 'a'+ThisThreadNum*LettersPerThread
    EndLetter = 'a'+ThisThreadNum*LettersPerThread+LettersPerThread
    DO i = StartLetter, EndLetter - 1
       write( *,FMT='(A)',ADVANCE='NO') char(i)
    END DO
  !$OMP END PARALLEL
write(*,*)
end
```

Debugging threaded applications is a complex process, because debuggers change the run-time performance, which can mask race conditions. Even `print` statements can mask issues, because they use synchronization and operating system functions. OpenMP* itself also adds some complications, because it introduces additional structure by distinguishing private variables and shared variables, and inserts additional code. A specialized debugger that supports OpenMP, such as the Intel® Debugger, can help you to examine variables and step through threaded code. You can also use the Intel® Thread Checker to detect many hard-to-find threading errors analytically. Sometimes, a process of elimination can help identify problems without resorting to sophisticated debugging tools.

Remember that most mistakes are race conditions. Most race conditions are caused by shared variables that really should have been declared private. Start by looking at the variables inside the parallel regions and make sure that the variables are declared private when necessary. Next, check functions called within parallel constructs.

The `DEFAULT(NONE)` clause, shown below, can be used to help find those hard-to-spot variables. If you specify `DEFAULT(NONE)`, then every variable must be declared with a data-sharing attribute clause.

Example

```
!$OMP PARALLEL DO DEFAULT(NONE) PRIVATE(x,y) SHARED(a,b)
```

Another common mistake is using uninitialized variables. Remember that private variables do not have initial values upon entering a parallel construct. Use the `FIRSTPRIVATE` and `LASTPRIVATE` clauses to initialize them only when necessary, because doing so adds extra overhead.

If you still can't find the bug, then consider the possibility of reducing the scope. Try a binary-hunt. Another method is to force large chunks of a parallel region to be critical sections. Pick a region of the code that you think contains the bug and place it within a critical section. Try to find the section of code that suddenly works when it is within a critical section and fails when it is not. Now look at the variables, and see if the bug is apparent. If that still doesn't work, try setting the entire program to run in serial by setting the compiler-specific environment variable `KMP_LIBRARY=serial`.

If the code is still not working, compile it without the `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows) option to make sure the serial version works.

Performance

OpenMP threaded application performance is largely dependent upon the following things:

- The underlying performance of the single-threaded code.
- CPU utilization, idle threads, and load balancing.
- The percentage of the application that is executed in parallel by multiple threads.
- The amount of synchronization and communication among the threads.
- The overhead needed to create, manage, destroy, and synchronize the threads, made worse by the number of single-to-parallel or parallel-to-single transitions called fork-join transitions.
- Performance limitations of shared resources such as memory, bus bandwidth, and CPU execution units.
- Memory conflicts caused by shared memory or falsely shared memory.

Performance always begins with a properly constructed parallel algorithm or application. For example, parallelizing a bubble-sort, even one written in hand-optimized assembly language, is not a good place to start. Keep scalability in mind; creating a program that runs well on two CPUs is not as efficient as creating one that runs well on *n* CPUs. With OpenMP, the number of threads is chosen by the compiler, so programs that work well regardless of the number of threads are highly desirable. Producer/consumer architectures are rarely efficient, because they are made specifically for two threads.

Once the algorithm is in place, make sure that the code runs efficiently on the targeted Intel® architecture; a single-threaded version can be a big help. Turn off the `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows) option to generate a single-threaded version, or build with `-openmp-stubs` (Linux and Mac OS X) or `/Qopenmp-stubs` (Windows), and run the single-threaded version through the usual set of optimizations.

Once you have gotten the single-threaded performance, it is time to generate the multi-threaded version and start doing some analysis.

Optimizations are really a combination of patience, experimentation, and practice. Make little test programs that mimic the way your application uses the computer resources to get a feel for what things are faster than others. Be sure to try the different scheduling clauses for the parallel sections of code.

OpenMP* Examples

The following examples show how to use several OpenMP* features.

A Simple Difference Operator

This example shows a simple parallel loop where the amount of work in each iteration is different. Dynamic scheduling is used to improve load balancing.

The END DO has a NOWAIT because there is an implicit barrier at the end of the parallel region.

Example

```
subroutine do_1(a,b,n)
  real a(n,n), b(n,n)
  !$OMP PARALLEL SHARED(A,B,N)
     !$OMP DO SCHEDULE(DYNAMIC,1) PRIVATE(I,J)
       do i = 2, n
          do j = 1, i
            b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
          end do
      end do
  !$OMP END DO NOWAIT
!$OMP END PARALLEL
end
```

Two Difference Operators: DO Loop Version

The example uses two parallel loops fused to reduce fork/join overhead. The first `END DO` directive has a `NOWAIT` clause because all the data used in the second loop is different than all the data used in the first loop.

Example

```
subroutine do_2(a,b,c,d,m,n)
  real a(n,n), b(n,n), c(m,m), d(m,m)
  !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
    !$OMP DO SCHEDULE(DYNAMIC,1)
      do i = 2, n
        do j = 1, i
          b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
        end do
      end do
    !$OMP END DO NOWAIT
    !$OMP DO SCHEDULE(DYNAMIC,1)
      do i = 2, m
        do j = 1, i
          d(j,i) = ( c(j,i) + c(j,i-1) ) / 2.0
        end do
      end do
    !$OMP END DO NOWAIT
  !$OMP END PARALLEL
end
```

Two Difference Operators: SECTIONS Version

The example demonstrates the use of the SECTIONS directive. The logic is identical to the preceding DO example, but uses SECTIONS instead of DO. Here the speedup is limited to 2 because there are only two units of work whereas in the example above there are n-1 + m-1 units of work.

Example

```
subroutine sections_1(a,b,c,d,m,n)
  real a(n,n), b(n,n), c(m,m), d(m,m)
  !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
    !$OMP SECTIONS
       !$OMP SECTION
          do i = 2, n
             do j = 1, i
                b(j,i)=( a(j,i) + a(j,i-1) ) / 2.0
             end do
          end do
       !$OMP SECTION
          do i = 2, m
             do j = 1, i
                d(j,i)=( c(j,i) + c(j,i-1) ) / 2.0
             end do
          end do
    !$OMP END SECTIONS NOWAIT
  !$OMP END PARALLEL
end
```

Updating a Shared Scalar

This example demonstrates how to use a `SINGLE` construct to update an element of the shared array `a`. The optional nowait after the first loop is omitted because it is necessary to wait at the end of the loop before proceeding into the `SINGLE` construct.

Example

```
subroutine sp_1a(a,b,n)
  real a(n), b(n)
  !$OMP PARALLEL SHARED(A,B,N) PRIVATE(I)
    !$OMP DO
       do i = 1, n
         a(i) = 1.0 / a(i)
       end do
    !$OMP SINGLE
      a(1) = min( a(1), 1.0 )
    !$OMP END SINGLE
    !$OMP DO
      do i = 1, n
        b(i) = b(i) / a(i)
      end do
    !$OMP END DO NOWAIT
  !$OMP END PARALLEL
end
```

Libraries, Directives, Clauses, and Environmental Variables

OpenMP* Environment Variables

The Intel® Compiler supports OpenMP* environment variables (with the OMP_ prefix) and extensions in the form of Intel-specific environment variables (with the KMP_ prefix).

OpenMP Environment Variables

The syntax examples assume bash on Linux* and Mac OS* X. Use the `set` command for Windows*.

Variable Name	Default	Description and Syntax
`OMP_NUM_THREADS`	Number of processors visible to the operating system.	Sets the maximum number of threads to use for OpenMP* parallel regions if no other value is specified in the application. This environment variable applies to both `-openmp` and `-parallel` (Linux and Mac OS X) or `/Qopenmp` and `/Qparallel` (Windows). Example syntax: `export OMP_NUM_THREADS=value`
`OMP_SCHEDULE`	`STATIC`, no chunk size specified	Sets the run-time schedule type and an optional chunk size. Example syntax: `export OMP_SCHEDULE="kind[,chunk_size]"`
`OMP_DYNAMIC`	`.FALSE.` 0	Enables (`.TRUE.`) or disables (`.FALSE.`) the dynamic adjustment of the number of threads. Example syntax: `export OMP_DYNAMIC=value`

Variable Name	Default	Description and Syntax
OMP_NESTED	.FALSE. 0	Enables (.TRUE.) or disables (.FALSE.)nested parallelism. Example syntax: export OMP_NESTED=value
OMP_STACKSIZE	IA-32 architecture: 2M Intel® 64 and IA-32 Architecures: 4M	Sets the number of bytes to allocate for each OpenMP thread to use as the private stack for the thread. Recommended size is 16M. Use the optional suffixes: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If only value is specified and B, K, M, G, or T is not specified, then size is assumed to be K (Kilobytes). This variable does not affect the native operating system threads created by the user program nor the thread executing the sequential part of an OpenMP program or parallel programs created using -parallel (Linux and Mac OS X) or /Qparallel (Windows). kmp_{set,get}_stacksize_s() routines set/retrieve the value. kmp_set_stacksize_s() routine must be called from sequential part, before first

Variable Name	Default	Description and Syntax
		parallel region is created. Otherwise, calling `kmp_set_stacksize_s()` has no effect. Related env variables: `KMP_STACKSIZE`. `KMP_STACKSIZE` overrides `OMP_STACKSIZE`. Example syntax: `export OMP_STACKSIZE=value`
`OMP_MAX_ACTIVE_LEVELS`	No enforced limit	Limits the number of simultaneously executing threads in an OpenMP program. If this limit is reached and another native operating system thread encounters OpenMP API calls or constructs, the program can abort with an error message. If this limit is reached when an OpenMP parallel region begins, a one-time warning message might be generated indicating that the number of threads in the team was reduced, but the program will continue. This environment variable is only used for programs compiled with the following options: `-openmp` or `-openmp-profile` or `-parallel`

Variable Name	Default	Description and Syntax
OMP_THREAD_LIMIT	No enforced limit	(Linux and Mac OS X) and /Qopenmp or /Qopenmp-profile or /Qparallel (Windows). omp_get_thread_limit() routine returns the value of the limit. Related env variable: KMP_ALL_THREADS. OMP_THREAD_LIMIT overrides KMP_ALL_THREADS. Example syntax: export OMP_THREAD_LIMIT=value Limits the number of simultaneously executing threads in an OpenMP* program. If this limit is reached and another native operating system thread encounters OpenMP* API calls or constructs, the program can abort with an error message. If this limit is reached when an OpenMP parallel region begins, a one-time warning message might be generated indicating that the number of threads in the team was reduced, but the program will continue.

Variable Name	Default	Description and Syntax
		This environment variable is only used for programs compiled with the following options: -openmp or `-openmp-profile` or `-parallel` (Linux and Mac OS X) and `/Qopenmp` or `/Qopenmp-profile` or `/Qparallel` (Windows). omp_get_thread_limit() routine returns the value of the limit. Related environment variable: KMP_ALL_THREADS. Its value overrides OMP_THREAD_LIMIT. Example syntax: `export OMP_THREAD_LIMIT=value`

Intel Environment Variables Extensions

Variable Name	Default	Description
`KMP_ALL_THREADS`	No enforced limit	Limits the number of simultaneously executing threads in an OpenMP* program. If this limit is reached and another native operating system thread encounters OpenMP* API calls or constructs, the program can

Variable Name	Default	Description
		abort with an error message. If this limit is reached when an OpenMP parallel region begins, a one-time warning message might be generated indicating that the number of threads in the team was reduced, but the program will continue. This environment variable is only used for programs compiled with the following options: `-openmp` or `-openmp-profile` (Linux and Mac OS X) and `/Qopenmp` or `/Qopenmp-profile` (Windows).
`KMP_BLOCKTIME`	200 milliseconds	Sets the time, in milliseconds, that a thread should wait, after completing the execution of a parallel region, before sleeping. Use the optional character suffixes: `s` (seconds), `m` (minutes), `h` (hours), or `d` (days) to specify the units. Specify `infinite` for an unlimited wait time. See also the throughput execution mode and the `KMP_LIBRARY` environment variable.

Variable Name	Default	Description
KMP_LIBRARY	throughput	Selects the OpenMP run-time library execution mode. The options for the variable value are throughput, turnaround, and serial.
KMP_SETTINGS	0	Enables (1) or disables (0) the printing OpenMP run-time library environment variables during program execution. Two lists of variables are printed: user-defined environment variables settings and effective values of variables used by OpenMP run-time library.
KMP_STACKSIZE	IA-32 architecture: 2m Intel® 64 and IA-64 architectures: 4m	Sets the number of bytes to allocate for each OpenMP* thread to use as the private stack for the thread. Recommended size is 16m. Use the optional suffixes: b (bytes), k (kilobytes), m (megabytes), g (gigabytes), or t (terabytes) to specify the units. This variable does not affect the native operating system threads created by the user program nor the thread executing the sequential part of an OpenMP* program or parallel programs created

Variable Name	Default	Description
		using `-parallel` (Linux and Mac OS X) or `/Qparallel` (Windows).
`KMP_MONITOR_STACKSIZE`	max (32k, system minimum thread stack size)	Sets the number of bytes to allocate for the monitor thread, which is used for book-keeping during program execution. Use the optional suffixes: `b` (bytes), `k` (kilobytes), `m` (megabytes), `g` (gigabytes), or `t` (terabytes) to specify the units.
`KMP_VERSION`	`.FALSE.` 0	Enables (`.TRUE.`) or disables (`.FALSE.`) the printing of OpenMP run-time library version information during program execution.
`KMP_AFFINITY`	`noverbose, respect, granularity=core`	Enables run-time library to bind threads to physical processing units. See Thread Affinity Interface for more information on the default and the affect this environment variable has on the parallel environment.
`KMP_CPUINFO_FILE`	`none`	Specifies an alternate file name for file containing machine topology description. The file must be in the same format as `/proc/cpuinfo`.

GNU Environment Variables Extensions

These environment variables are GNU extensions. They are recognized by the Intel OpenMP compatibility library.

Variable Name	Default	Description
GOMP_STACKSIZE	See OMP_STACKSIZE description	OMP_STACKSIZE overrides GOMP_STACKSIZE. KMP_STACKSIZE overrides OMP_STACKSIZE and GOMP_STACKSIZE
GOMP_CPU_AFFINITY	TBD	

OpenMP* Directives and Clauses Summary

This is a summary of the OpenMP* directives and clauses supported in the Intel® Compiler. For detailed information about the OpenMP API, see the *OpenMP Application Program Interface* Version 2.5 specification, which is available from the OpenMP web site (http://www.openmp.org/).

OpenMP Directives

Directive	Description
PARALLEL END PARALLEL	Defines a parallel region.
TASK END TASK	Defines a task region.
DO END DO	Identifies an iterative worksharing construct in which the iterations of the associated loop should be divided among threads in a team.
SECTIONS END SECTIONS	Identifies a non-iterative worksharing construct that specifies a set of structured blocks that are to be divided among threads in a team.
SECTION	Indicates that the associated structured block should be executed in parallel as part of the enclosing sections construct.

Directive	Description
SINGLE END SINGLE	Identifies a construct that specifies that the associated structured block is executed by only one thread in the team.
PARALLEL DO END PARALLEL DO	A shortcut for a PARALLEL region that contains a single DO directive.
	 **NOTE.** The OpenMP PARALLEL DO or DO directive must be immediately followed by a DO statement (DO-stmt as defined by R818 of the ANSI Fortran standard). If you place another statement or an OpenMP directive between the PARALLEL DO or DO directive and the DO statement, the compiler issues a syntax error.
PARALLEL SECTIONS END PARALLEL SECTIONS	Provides a shortcut form for specifying a parallel region containing a single SECTIONS construct.
MASTER END MASTER	Identifies a construct that specifies a structured block that is executed by only the master thread of the team.
CRITICAL[*name*] END CRITICAL[*name*]	Identifies a construct that restricts execution of the associated structured block to a single thread at a time. Each thread waits at the beginning of the critical construct until no other thread is executing a critical construct with the same name argument.
TASKWAIT	Indicates a wait on the completion of child tasks generated since the beginning of the current task.
BARRIER	Synchronizes all the threads in a team. Each thread waits until all of the other threads in that team have reached this point.
ATOMIC	Ensures that a specific memory location is updated atomically, rather than exposing it to the possibility of multiple, simultaneously writing threads.

Directive	Description
FLUSH [(*list*)]	Specifies a cross-thread sequence point at which the implementation is required to ensure that all the threads in a team have a consistent view of certain objects in memory. The optional *list* argument consists of a comma-separated list of variables to be flushed.
ORDERED END ORDERED	The enclosed structured block is executed in the order in which iterations would be executed in a sequential loop.
THREADPRIVATE (*list*)	Makes the named COMMON blocks or variables private to a thread. The list argument consists of a comma-separated list of COMMON blocks or variables.

OpenMP Clauses

Clause	Description
PRIVATE (*list*)	Declares variables in *list* to be PRIVATE to each thread in a team.
FIRSTPRIVATE (*list*)	Same as PRIVATE, but the copy of each variable in the *list* is initialized using the value of the original variable existing before the construct.
LASTPRIVATE (*list*)	Same as PRIVATE, but the original variables in *list* are updated using the values assigned to the corresponding PRIVATE variables in the last iteration in the DO construct loop or the last SECTION construct.
COPYPRIVATE (*list*)	Uses private variables in *list* to broadcast values, or pointers to shared objects, from one member of a team to the other members at the end of a single construct.
NOWAIT	Specifies that threads need not wait at the end of worksharing constructs until they have completed execution. The threads may proceed past the end of the worksharing constructs as soon as there is no more work available for them to execute.
SHARED (*list*)	Shares variables in *list* among all the threads in a team.

Clause	Description
DEFAULT (*mode*)	Determines the default data-scope attributes of variables not explicitly specified by another clause. Possible values for *mode* are PRIVATE, SHARED, or NONE.
REDUCTION ({*operator*|*intrinsic*}:*list*)	Performs a reduction on variables that appear in *list* with the operator operator or the intrinsic procedure name intrinsic; operator is one of the following: +, *, .AND., .OR., .EQV., .NEQV.; intrinsic refers to one of the following: MAX, MIN, IAND, IOR, or IEOR.
ORDERED END ORDERED	Used in conjunction with a DO or SECTIONS construct to impose a serial order on the execution of a section of code. If ORDERED constructs are contained in the dynamic extent of the DO construct, the ordered clause must be present on the DO directive.
IF (*expression*)	The enclosed parallel region is executed in parallel only if the *expression* evaluates to .TRUE., otherwise the parallel region is serialized. The expression must be scalar logical.
NUM_THREADS (*expression*)	Requests the number of threads specified by expression for the parallel region. The expressions must be scalar integers.
SCHEDULE (*type*[,*chunk*])	Specifies how iterations of the DO construct are divided among the threads of the team. Possible values for the *type* argument are STATIC, DYNAMIC, GUIDED, and RUNTIME. The optional *chunk* argument must be a positive scalar integer expression.
COLLAPSE (n)	Specifies how many loops are associated with the OpenMP loop construct for collapsing.
COPYIN (*list*)	Provide a mechanism to specify that the master thread data values be copied to the THREADPRIVATE copy of the common blocks or variables specified in *list* at the beginning of the parallel region.

Clause	Description
UNTIED	Indicates that a resumed task does not have to be executed by same thread executing it before it was suspended.

Directives and Clauses Cross-reference

See Data Scope Attribute Clauses Overview.

Directive	Use these Clauses
PARALLEL END PARALLEL	• IF • NUM_THREADS • DEFAULT • PRIVATE • FIRSTPRIVATE • SHARED • COPYIN • REDUCTION
DO END DO	• SCHEDULE • PRIVATE • FIRSTPRIVATE • LASTPRIVATE • REDUCTION • ORDERED • NOWAIT • COLLAPSE

OpenMP* Library Support

OpenMP* Run-time Library Routines

OpenMP* provides several run-time library routines to help you manage your program in parallel mode. Many of these run-time library routines have corresponding environment variables that can be set as defaults. The run-time library routines let you dynamically change these factors to assist in controlling your program. In all cases, a call to a run-time library routine overrides any corresponding environment variable.

This topic provides a summary of the OpenMP run-time library routines. See OpenMP* Support Overview for additional resources; refer to the OpenMP API Version 3.0 specification for detailed information about using these routines.

The following tables specify the interfaces to these routines. (The names for the routines are in user name space.)

Execution Environment Routines

Use these routines to monitor and influence threads and the parallel environment.

Function	Description
`SUBROUTINE OMP_SET_NUM_THREADS(num_threads)` `INTEGER num_threads`	Sets the number of threads to use for subsequent parallel regions created by the calling thread.
`INTEGER FUNCTION OMP_GET_NUM_THREADS()`	Returns the number of threads that are being used in the current parallel region.

Function	Description
	This function does not return the value inherited by the calling thread from the `OMP_SET_NUM_THREADS()` function.
`INTEGER FUNCTION OMP_GET_MAX_THREADS()`	Returns the number of threads available to subsequent parallel regions created by the calling thread. This function returns the value inherited by the calling thread from the `OMP_SET_NUM_THREADS()` function.
`INTEGER FUNCTION OMP_GET_THREAD_NUM()`	Returns the thread number of the calling thread, within the context of the current parallel region..
`INTEGER FUNCTION OMP_GET_NUM_PROCS()`	Returns the number of processors available to the program.
`LOGICAL FUNCTION OMP_IN_PARALLEL()`	Returns `.TRUE.` if called within the dynamic extent of a parallel region executing in parallel; otherwise returns `.FALSE.`.
`SUBROUTINE` OMP_SET_DYNAMIC(dynamic_threads) LOGICAL dynamic_threads	Enables or disables dynamic adjustment of the number of threads used to execute a parallel region. If *`dynamic_threads`* is `.TRUE.`, dynamic threads are enabled. If *`dynamic_threads`* is `.FALSE.`, dynamic threads are disabled. Dynamic threads are disabled by default.
`LOGICAL FUNCTION OMP_GET_DYNAMIC()`	Returns `.TRUE.` if dynamic thread adjustment is enabled, otherwise returns `.FALSE.`.
`SUBROUTINE OMP_SET_NESTED(nested)` `LOGICAL nested`	Enables or disables nested parallelism. If *`nested`* is `.TRUE.`, nested parallelism is enabled. If *`nested`* is `.FALSE.`, nested parallelism is disabled. Nested parallelism is disabled by default.

Function	Description
`LOGICAL FUNCTION OMP_GET_NESTED()`	Returns `.TRUE.` if nested parallelism is enabled, otherwise returns `.FALSE.`.
SUBROUTINE OMP_SET_SCHEDULE(kind,modifier) INTEGER(KIND=omp_sched_t) kind INTEGER modifier	Determines the schedule of a worksharing loop that is applied when 'runtime' is used as schedule kind.

`SUBROUTINE OMP_GET_SCHEDULE(kind,modifier)`
`INTEGER(KIND=omp_sched_t) kind`
`INTEGER modifier`
	Returns the schedule of a worksharing loop that is applied when the 'runtime' schedule is used.

`INTEGER FUNCTION OMP_GET_THREAD_LIMIT()`	Returns the maximum number of simultaneously executing threads in an OpenMP* program.
`SUBROUTINE OMP_SET_MAX_ACTIVE_LEVELS(max_active_levels)` `INTEGER max_active_levels`	Limits the number of nested active parallel regions. The call is ignored if negative max_active_levels specified.
`INTEGER FUNCTION OMP_GET_MAX_ACTIVE_LEVELS()`	Returns the maximum number of nested active parallel regions.
`INTEGER FUNCTION OMP_GET_ACTIVE_LEVEL()`	Returns the number of nested, active parallel regions enclosing the task that contains the call.
`INTEGER FUNCTION OMP_GET_LEVEL()`	Returns the number of nested parallel regions (whether active or inactive) enclosing the task that contains the call, not including the implicit parallel region.
`INTEGER FUNCTION OMP_GET_ANCESTOR_THREAD_NUM(level)` `INTEGER level`	Returns the thread number of the ancestor at a given nest level of the current thread.

Function	Description
`INTEGER FUNCTION OMP_GET_TEAM_SIZE(level) INTEGER level`	Returns the size of the thread team to which the ancestor belongs.

Lock Routines

Use these routines to affect OpenMP locks.

Function	Description
`SUBROUTINE OMP_INIT_LOCK(lock) INTEGER (KIND=OMP_LOCK_KIND)::lock`	Initializes the lock associated with *lock* for use in subsequent calls.
`SUBROUTINE OMP_DESTROY_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock`	Causes the lock specified by *lock* to become undefined or uninitialized. The lock must be initialized and not locked.
`SUBROUTINE OMP_SET_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock`	Forces the executing thread to wait until the lock associated with *lock* is available. The thread is granted ownership of the lock when it becomes available. The lock must be initialized.
`SUBROUTINE OMP_UNSET_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock`	Releases the executing thread from ownership of the lock associated with *lock*. The behavior is undefined if the executing thread does not own the lock associated with *lock*.
`LOGICAL OMP_TEST_LOCK(lock) INTEGER(KIND=OMP_LOCK_KIND)::lock`	Attempts to set the lock associated with *lock*. If successful, returns `.TRUE.`, otherwise returns `.FALSE.`. The lock must be initialized.
`SUBROUTINE OMP_INIT_NEST_LOCK(lock) INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock`	Initializes the nested lock associated with *lock* for use in the subsequent calls.
`SUBROUTINE OMP_DESTROY_NEST_LOCK(lock)`	Causes the nested lock associated with *lock* to become undefined or uninitialized. The lock must be initialized and not locked.

Function	Description
`INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock`	
`SUBROUTINE OMP_SET_NEST_LOCK(lock)` `INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock`	Forces the executing thread to wait until the nested lock associated with `lock` is available. The thread is granted ownership of the nested lock when it becomes available. The lock must be initialized.
`SUBROUTINE OMP_UNSET_NEST_LOCK(lock)` `INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock`	Releases the executing thread from ownership of the nested lock associated with `lock` if the nesting count is zero. Behavior is undefined if the executing thread does not own the nested lock associated with `lock`.
`INTEGER OMP_TEST_NEST_LOCK(lock)` `INTEGER(KIND=OMP_NEST_LOCK_KIND)::lock`	Attempts to set the nested lock specified by `lock`. If successful, returns the nesting count, otherwise returns zero.

Timing Routines

Function	Description
`DOUBLE PRECISION FUNCTION OMP_GET_WTIME()`	Returns a double precision value equal to the elapsed wall clock time (in seconds) relative to an arbitrary reference time. The reference time does not change during program execution.
`DOUBLE PRECISION FUNCTION OMP_GET_WTICK()`	Returns a double precision value equal to the number of seconds between successive clock ticks.

Intel Extension Routines to OpenMP*

The Intel® Compiler implements the following group of routines as an extensions to the OpenMP* run-time library:

- Getting and setting the execution environment
- Getting and setting stack size for parallel threads

- Memory allocation
- Getting and setting thread sleep time for the throughput execution mode

The Intel extension routines described in this section can be used for low-level tuning to verify that the library code and application are functioning as intended. These routines are generally not recognized by other OpenMP-compliant compilers, which may cause the link stage to fail in other compiler. These OpenMP routines require that you use the `-openmp-stubs` (Linux* and Mac OS* X) or `/Qopenmp-stubs` (Windows*) command-line option to execute.

See OpenMP* Run-time Library Routines for details about including support for these declarations in your source, and see OpenMP* Support Libraries for detailed information about execution environment (mode).

In most cases, environment variables can be used in place of the extension library routines. For example, the stack size of the parallel threads may be set using the `OMP_STACKSIZE` environment variable rather than the `KMP_SET_STACKSIZE_S()` library routine.

NOTE. A run-time call to an Intel extension routine takes precedence over the corresponding environment variable setting.

Execution Environment Routines

Function	Description
`SUBROUTINE KMP_SET_DEFAULTS(STRING) CHARACTER*(*) STRING`	Sets OpenMP environment variables defined as a list of variables separated by "|" in the argument.
`SUBROUTINE KMP_SET_LIBRARY_THROUGHPUT()`	Sets execution mode to throughput, which is the default. Allows the application to determine the runtime environment. Use in multi-user environments.
`SUBROUTINE KMP_SET_LIBRARY_TURNAROUND()`	Sets execution mode to turnaround. Use in dedicated parallel (single user) environments.
`SUBROUTINE KMP_SET_LIBRARY_SERIAL()`	Sets execution mode to serial.
`SUBROUTINE KMP_SET_LIBRARY(LIBNUM) INTEGER (KIND=OMP_INTEGER_KIND) LIBNUM`	Sets execution mode indicated by the value passed to the function. Valid values are:

Function	Description
	• 1 - serial mode • 2 - turnaround mode • 3 - throughput mode Call this routine before the first parallel region is executed.

`FUNCTION KMP_GET_LIBRARY()`
`INTEGER (KIND=OMP_INTEGER_KIND)`
`KMP_GET_LIBRARY`
	Returns a value corresponding to the current execution mode: 1 (serial), 2 (turnaround), or 3 (throughput).

Stack Size

For IA-64 architecture it is recommended to always use `KMP_SET_STACKSIZE_S()` and `KMP_GET_STACKSIZE_S()`. The `_S()` variants must be used if you need to set a stack size ≥ 2**31 bytes (2 gigabytes).

Function	Description

`FUNCTION KMP_GET_STACKSIZE_S()`
`INTEGER(KIND=KMP_SIZE_T_KIND) &`
`KMP_GET_STACKSIZE_S`
	Returns the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can be changed with `KMP_SET_STACKSIZE_S()` routine, prior to the first parallel region or via the `KMP_STACKSIZE` environment variable.

`FUNCTION KMP_GET_STACKSIZE()` `INTEGER KMP_GET_STACKSIZE`	Provided for backwards compatibility only. Use `KMP_GET_STACKSIZE_S()` routine for compatibility across different families of Intel processors.
`SUBROUTINE KMP_SET_STACKSIZE_S(`*`size`*`)` `INTEGER (KIND=KMP_SIZE_T_KIND)`*`size`*	Sets to *`size`* the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can also be set via the `KMP_STACKSIZE` environment variable. In order for `KMP_SET_STACKSIZE_S()kmp_set_stacksize_s()`

Function	Description
	to have an effect, it must be called before the beginning of the first (dynamically executed) parallel region in the program.
`SUBROUTINE KMP_SET_STACKSIZE_S(size)` `INTEGER size`	Provided for backward compatibility only. Use `KMP_SET_STACKSIZE_S(size)` for compatibility across different families of Intel processors.

Memory Allocation

The Intel® compiler implements a group of memory allocation routines as an extension to the OpenMP* run-time library to enable threads to allocate memory from a heap local to each thread. These routines are: `KMP_MALLOC()`, `KMP_CALLOC()`, and `KMP_REALLOC()`.

The memory allocated by these routines must also be freed by the `KMP_FREE()` routine. While it is legal for the memory to be allocated by one thread and freed by a different thread, this mode of operation has a slight performance penalty.

Working with the local heap might lead to improved application performance since synchronization is not required.

Function	Description

`FUNCTION KMP_MALLOC(size)`
`INTEGER(KIND=KMP_POINTER_KIND)KMP_MALLOC`
`INTEGER(KIND=KMP_SIZE_T_KIND)size`
	Allocate memory block of *size* bytes from thread-local heap.

`FUNCTION KMP_CALLOC(nelem,elsize)`
`INTEGER(KIND=KMP_POINTER_KIND)KMP_CALLOC`
`INTEGER(KIND=KMP_SIZE_T_KIND)nelem`
`INTEGER(KIND=KMP_SIZE_T_KIND)elsize`
	Allocate array of *nelem* elements of size *elsize* from thread-local heap.

`FUNCTION KMP_REALLOC(ptr, size)`
`INTEGER(KIND=KMP_POINTER_KIND)KMP_REALLOC`
`INTEGER(KIND=KMP_POINTER_KIND) ptr`
`INTEGER(KIND=KMP_SIZE_T_KIND)size`
	Reallocate memory block at address *ptr* and *size* bytes from thread-local heap.

Function	Description
SUBROUTINE KMP_FREE(*ptr*) INTEGER (KIND=KMP_POINTER_KIND)*ptr*	Free memory block at address *ptr* from thread-local heap. Memory must have been previously allocated with KMP_MALLOC(), KMP_CALLOC(), or KMP_REALLOC().

Thread Sleep Time

In the throughput execution mode, threads wait for new parallel work at the ends of parallel regions, and then sleep, after a specified period of time. This time interval can be set by the KMP_BLOCKTIME environment variable or by the KMP_SET_BLOCKTIME() function.

Function	Description
FUNCTION KMP_GET_BLOCKTIME(INTEGER KMP_GET_BLOCKTIME	Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping, as set either by the KMP_BLOCKTIME environment variable or by KMP_SET_BLOCKTIME().
FUNCTION KMP_SET_BLOCKTIME(*msec*) INTEGER *msec*	Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping. This routine affects the block time setting for the calling thread and any OpenMP team threads formed by the calling thread. The routine does not affect the block time for any other threads.

OpenMP* Support Libraries

The Intel® Compiler provides support libraries for OpenMP*. There are several kinds of libraries:

- Performance: supports parallel OpenMP execution.
- Profile: supports parallel OpenMP execution and allows use of Intel® Thread Profiler.
- Stubs: supports serial execution of OpenMP applications.

Each kind of library is available for both dynamic and static linking.

NOTE. The use of static OpenMP libraries is not recommended, because they might cause multiple libraries to be linked in an application. The condition is not supported and could lead to unpredictable results.

This section describes the compatibility libraries and legacy libraries provided with the Intel compiler, as well as the selection of run-time execution modes.

Compatibility Libraries

To use the Compatibility OpenMP libraries, specify the (default) `/Qopenmp-lib:compat` (Windows OS) or `-openmp-lib compat` (Linux OS and Mac OS X) compiler option during linking.

On Linux and Mac OS X systems, to use dynamically linked libraries during linking, specify `-openmp-link=dynamic` option; to use static linking, specify the `-openmp-link=static` option.

On Windows systems, to use dynamically linked libraries during linking, specify the `/MD` and `/Qopenmp-link:dynamic` options; to use static linking, specify the `/MT` and `/Qopenmp-link:static` options.

To provide run-time support for dynamically linked applications, the supplied DLL (Windows OS) or shared library (Linux OS and Mac OS X) must be available to the application at run time.

Performance Libraries

To use these libraries, specify the `-openmp` (Linux* and Mac OS* X) or `/Qopenmp` (Windows*) compiler option.

Operating System	Dynamic Link	Static Link
Linux	`libiomp5.so`	`libiomp5.a`
Mac OS X	`libiomp5.dylib`	`libiomp5.a`
Windows	`libiomp5md.lib` `libiomp5md.dll`	`libiomp5mt.lib`

Profile Libraries

To use these libraries, specify `-openmp-profile` (Linux* and Mac OS* X) or `/Qopenmp-profile` (Windows*) compiler option. These allow you to use Intel® Thread Profiler to analyze OpenMP applications.

Operating System	Dynamic Link	Static Link
Linux	`libiompprof5.so`	`libiompprof5.a`
Mac OS X	`libiompprof5.dylib`	`libiompprof5.a`
Windows	`libiompprof5md.lib` `libiompprof5md.dll`	`libiompprof5mt.lib`

Stubs Libraries

To use these libraries, specify `-openmp-stubs` (Linux* and Mac OS* X) or `/Qopenmp-stubs` (Windows*) compiler option. These allow you to compile OpenMP applications in serial mode and provide stubs for OpenMP routines and extended Intel-specific routines.

Operating System	Dynamic Link	Static Link
Linux	`libiompstubs5.so`	`libiompstubs5.a`
Mac OS X	`libiompstubs5.dylib`	`libiompstubs5.a`
Windows	`libiompstubs5md.lib` `libiompstubs5md.dll`	`libiompstubs5mt.lib`

Legacy Libraries

To use the Legacy OpenMP libraries, specify the `/Qopenmp-lib:legacy` (Windows OS) or `-openmp-lib legacy` (Linux OS and Mac OS X) compiler options during linking. Legacy libraries are deprecated.

On Linux and Mac OS X systems, to use dynamically linked libraries during linking, specify the `-openmp-link:dynamic` option; to use static linking, specify the `-openmp-link:static` option.

On Windows systems, to use dynamically linked libraries during linking, specify the `/MD` and `/Qopenmp-link=dynamic` options; to use static linking, specify the `/MT` and `/Qopenmp-link=static` options.

To provide run-time support for dynamically linked applications, the supplied DLL (Windows OS) or shared library (Linux OS and Mac OS X) must be available to the application at run time.

Performance Libraries

To use these libraries, specify `-openmp` (Linux* and Mac OS* X) or `/Qopenmp` (Windows*) compiler option.

Operating System	Dynamic Link	Static Link
Linux	`libguide.so`	`libguide.a`
Mac OS X	`libguide.dylib`	`libguide.a`
Windows	`libguide40.lib` `libguide40.dll`	`libguide.lib`

Profile Libraries

To use these libraries, specify `-openmp-profile` (Linux* and Mac OS* X) or `/Qopenmp-profile` (Windows*) compiler option. These allow you to use Intel® Thread Profiler to analyze OpenMP applications.

Operating System	Dynamic Link	Static Link
Linux	`libguide_stats.so`	`libguide_stats.a`
Mac OS X	`libguide_stats.dylib`	`libguide_stats.a`
Windows	`libguide40_stats.lib` `libguide40_stats.dll`	`libguide_stats.lib`

Stubs Libraries

To use these libraries, specify `-openmp-stubs` (Linux* and Mac OS* X) or `/Qopenmp-stubs` (Windows*) compiler option. These allow you to compile OpenMP applications in serial mode and provide stubs for OpenMP routines and extended Intel-specific routines.

Operating System	Dynamic Link	Static Link
Linux	`libompstub.so`	`libompstub.a`
Mac OS X	`libompstub.dylib`	`libompstub.a`

Operating System	Dynamic Link	Static Link
Windows	libompstub40.lib libompstub40.dll	libompstub.lib

Execution modes

The Intel compiler enables you to run an application under different execution modes specified at run time; the libraries support the turnaround, throughput, and serial modes. Use the KMP_LIBRARY environment variable to select the modes at run time.

Mode	Description
throughput (default)	The throughput mode allows the program to detect its environment conditions (system load) and adjust resource usage to produce efficient execution in a dynamic environment. In a multi-user environment where the load on the parallel machine is not constant or where the job stream is not predictable, it may be better to design and tune for throughput. This minimizes the total time to run multiple jobs simultaneously. In this mode, the worker threads yield to other threads while waiting for more parallel work. After completing the execution of a parallel region, threads wait for new parallel work to become available. After a certain period of time has elapsed, they stop waiting and sleep. Until more parallel work becomes available, sleeping allows processor and resources to be used for other work by non-OpenMP threaded code that may execute between parallel regions, or by other applications. The amount of time to wait before sleeping is set either by the KMP_BLOCKTIME environment variable or by the

Mode	Description
turnaround	`KMP_SET_BLOCKTIME()` function. A small blocktime value may offer better overall performance if your application contains non-OpenMP threaded code that executes between parallel regions. A larger blocktime value may be more appropriate if threads are to be reserved solely for use for OpenMP execution, but may penalize other concurrently-running OpenMP or threaded applications. The turnaround mode is designed to keep active all processors involved in the parallel computation, which minimizes execution time of a single job. In this mode, the worker threads actively wait for more parallel work, without yielding to other threads. In a dedicated (batch or single user) parallel environment where all processors are exclusively allocated to the program for its entire run, it is most important to effectively use all processors all of the time.  **NOTE.** Avoid over-allocating system resources. The condition can occur if either too many threads have been specified, or if too few processors are available at run time. If system resources are over-allocated, this mode will cause poor performance. The throughput mode should be used instead if this occurs.
serial	The serial mode forces parallel applications to run as a single thread.

Using the OpenMP Compatibility Libraries

This section describes the steps needed to set up and use the OpenMP Compatibility Libraries from the command line. On Windows* systems, you can also build applications compiled with the OpenMP Compatibility libraries in the Microsoft Visual Studio* development environment.

For a summary of the support provided by the Compatibility and Legacy libraries provided with Intel compilers, see OpenMP* Source Compatibility and Interoperability with Other Compilers.

For a list of the options and libraries used by the OpenMP libraries, see OpenMP Support Libraries.

Set up your environment for access to the Intel compiler to ensure that the appropriate OpenMP library is available during linking. On Windows systems, you can either execute the appropriate batch (.bat) file or use the command-line window supplied in the compiler program folder that already has the environment set up. On Linux and Mac OS systems, you can source the appropriate script file (see Using the ifortvars File to Specify Location of Components.

During C/C++ compilation, ensure the version of `omp.h` used when compiling is the version provided by that compiler. For example, on Linux systems when compiling with the GNU C/C++ compiler, use the `omp.h` provided with the GNU C/C++ compiler. Similarly, during Fortran compilation, ensure that the version of `omp_lib.h` or `omp_lib.mod` used when compiling is the version provided by that compiler.

The following table lists the commands used by the various command-line compilers for both C and C++ source files.:

Operating System	C Source Module	C++ Source Module
Linux*	GNU: `gcc` Intel: `icc`	GNU: `g++` Intel: `icpc`
Mac OS* X	GNU: `gcc` Intel: `icc`	GNU: `g++` Intel: `icpc`
Windows*	Visual C++: `cl` Intel: `icl`	Visual C++: `cl` Intel: `icl`

The command for the Intel® Fortran compiler is `ifort` on Linux, Mac OS X, and Windows operating systems.

For information on the OpenMP libraries and options used by the Intel compiler, see OpenMP Support Libraries.

Command-Line Examples, Windows OS

On Windows systems, to use the Compatibility Libraries with Microsoft Visual C++ in the Microsoft Visual Studio* environment, see Using the OpenMP Compatibility Libraries from Visual Studio*.

To compile and link (build) the entire application with one command using the Compatibility libraries, specify the following Intel compiler command:

Type of File	Commands
Fortran source, dynamic link	`ifort /MD /Qopenmp /Qopenmp-lib:compat hello.f90`

By default, the Intel compilers perform a dynamic link of the OpenMP libraries. To perform a static link (not recommended), use the `/MT` option in place of the `/MD` option above and add the option `/Qopenmp-link:static`. The Intel compiler option `/Qopenmp-link` controls whether the linker uses static or dynamic OpenMP libraries on Windows OS systems (default is `/Qopenmp-link:dynamic`).

When using Microsoft Visual C++ compiler, you should link with the Intel OpenMP compatibility library. You need to avoid linking the Microsoft OpenMP run-time library (vcomp) and explicitly pass the name of the Intel OpenMP compatibility library as linker options (following `/link`):

Type of File	Commands
C source, dynamic link	`icl /MD /openmp hello.c /link /nodefaultlib:vcomp libiomp5md.lib`
C++ source, dynamic link	`icl /MD /openmp hello.cpp /link /nodefaultlib:vcomp libiomp5md.lib`

Performing a static link is not recommended, but would require use of the `/MT` option in place of the `/MD` option above.

You can also use both Intel C++ and Visual C++ compilers to compile parts of the application and create object files (object-level interoperability). In this example, the Intel compiler links the entire application:

Type of File	Commands

C source, dynamic link	`icl /MD /openmp hello.cpp /c f1.c f2.c`
	`icl /MD /Qopenmp /Qopenmp-lib:compat /c f3.c f4.c`
	`icl /MD /Qopenmp /Qopenmp-lib:compat f1.obj f2.obj f3.obj f4.obj /Feapp /link /nodefaultlib:vcomp`

The first command produces two object files compiled by Visual C++ compiler, and the second command produces two more object files compiled by Intel C++ Compiler. The final command links all four object files into an application.

Alternatively, the third line below uses the Visual C++ linker to link the application and specifies the Compatibility library `libiomp5md.lib` at the end of the third command:

Type of File	Commands

C source, dynamic link	`icl /MD /openmp hello.cpp /c f1.c f2.c`
	`icl /MD /Qopenmp /Qopenmp-lib:compat /c f3.c f4.c`
	`link f1.obj f2.obj f3.obj f4.obj /out:app.exe /nodefaultlib:vcomp libiomp5md.lib`

The following example shows the use of interprocedural optimization by the Intel compiler on several files, the Visual C++ compiler compiles several files, and the Visual C++ linker links the object files to create the executable:

Type of File	Commands

C source, dynamic link	`icl /MD /Qopenmp /Qopenmp-lib:compat /O3 /Qipo /Qipo-c f1.c f2.c f3.c`
	`cl /MD /openmp /O2 /c f4.c f5.c`
	`cl /MD /openmp /O2 ipo_out.obj f4.obj f5.obj /Feapp /link /nodefaultlib:vcomp libiomp5md.lib`

The first command uses the Intel® C++ Compiler to produce an optimized multi-file object file named `ipo_out.obj` by default (the `/Fe` option is not required; see Using IPO). The second command uses the Visual C++ compiler to produce two more object files. The third command uses the Visual C++ `cl` command to link all three object files using the Intel compiler OpenMP Compatibility library. Performing a static link (not recommended) requires use of the `/MT` option in place of the `/MD` option in each line above.

Command-Line Examples, Linux OS and Mac OS X

To compile and link (build) the entire application with one command using the Compatibility libraries, specify the following Intel compiler command:

Type of File	Commands
Fortran source	`ifort -openmp -openmp-lib=compat hello.f90`

By default, the Intel compilers perform a dynamic link of the OpenMP libraries. To perform a static link (not recommended), add the option `-openmp-link static`. The Intel compiler option `-openmp-link` controls whether the linker uses static or dynamic OpenMP libraries on Linux OS and Mac OS X systems (default is `-openmp-link dynamic`).

You can also use both Intel C++ `icc/icpc` and GNU `gcc/g++` compilers to compile parts of the application and create object files (object-level interoperability). In this example, the GNU compiler compiles the C file `foo.c` (the `gcc` option `-fopenmp` enables OpenMP support), and the Intel compiler links the application using the OpenMP Compatibility library:

Type of File	Commands
C source	`gcc -fopenmp -c foo.c` `icc -openmp -openmp-lib=compat foo.o`
C++ source	`g++ -fopenmp -c foo.cpp` `icpc -openmp -openmp-lib=compat foo.o`

When using GNU `gcc` or `g++` compiler to link the application with the Intel compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP compatibility library name using the `-l` option, the GNU `pthread` library using the `-l` option, and path to the Intel libraries where the Intel C++ compiler is installed using the `-L` option:

Type of File	Commands
C source	`gcc -fopenmp -c foo.c bar.c` `gcc foo.o bar.o -liomp5 -lpthread -L<icc_dir>/lib`

You can mix object files, but it is easier to use the Intel compiler to link the application so you do not need to specify the `gcc -l` option, `-L` option, and the `-lpthread` option:

Type of File	Commands

C source	`gcc -fopenmp -c foo.c`
	`icc -openmp -c bar.c`
	`icc -openmp -openmp=compat foo.o bar.o`

You can mix OpenMP object files compiled with the GNU gcc compiler, the Intel® C++ Compiler, and the Intel® Fortran Compiler. This example uses use the Intel Fortran Compiler to link all the objects:

Type of File	Commands
Mixed C and Fortran sources	`ifort -openmp -c foo.f` `icc -openmp -c ibar.c`

Type of File	Commands
	gcc -fopenmp -c gbar.c ifort -openmp -openmp-lib=compat foo.o ibar.o gbar.o

When using the Intel Fortran compiler, if the main program does not exist in a Fortran object file that is compiled by the Intel Fortran Compiler `ifort`, specify the `-nofor-main` option on the `ifort` command line during linking.

NOTE. Do not mix objects created by the Intel Fortran Compiler (`ifort`) with the GNU Fortran Compiler (`gfortran`); instead, recompile all Fortran sources with the same Fortran compiler. The GNU Fortran Compiler is only available on Linux operating systems.

Similarly, you can mix object files compiled with the Intel® C++ Compiler, the GNU C/C++ compiler, and the GNU Fortran Compiler (gfortran), if you link with the GNU Fortran Compiler (`gfortran`). When using GNU `gfortran` compiler to link the application with the Intel compiler OpenMP compatibility library, you need to explicitly pass the Intel OpenMP compatibility library name and the Intel `irc` libraries using the `-l` options, the GNU `pthread` library using the `-l` option, and path to the Intel libraries where the Intel C++ compiler is installed using the `-L`. option. You do not need to specify the `-fopenmp` option on the link line:

Type of File	Commands
Mixed C and GNU Fortran sources	gfortran -fopenmp -c foo.f icc -openmp -c ibar.c gcc -fopenmp -c gbar.c gfortran foo.o ibar.o gbar.o -lirc -liomp5 -lpthread -lc -L<icc_dir>/lib

Alternatively, you could use the Intel compiler to link the application, but need to pass multiple `gfortran` libraries using the `-l` options on the link line:

Type of File	Commands
Mixed C and Fortran sources	gfortran -fopenmp -c foo.f icc -openmp -c ibar.c icc -openmp -openmp-lib=compat foo.o bar.o -lgfortranbegin -lgfortran

Using the OpenMP Compatibility Libraries from Visual Studio

When using systems running a Windows OS, you can make certain changes in the Visual C++ Visual Studio 2005 development environment to allow you to use the Intel C++ Compiler and Visual C++ to create applications that use the Intel compiler OpenMP Compatibility libraries.

NOTE. Microsoft Visual C++ must have the symbol `_OPENMP_NOFORCE_MANIFEST` defined or it will include the manifest for the `vcomp90` dlls. While this may not appear to cause a problem on the build system, it will cause a problem when the application is moved to another system that does not have this DLL installed.

Set the project Property Pages to indicate the Intel OpenMP run-time library location:

1. Open the project's property pages in from the main menu: Project > Properties (or right click the Project name and select Properties) .
2. Select Configuration Properties > Linker > General > Additional Library Directories
3. Enter the path to the Intel compiler libraries. For example, for an IA-32 architecture system, enter: `< Intel_compiler_installation_path>\IA32\LIB`

Make the Intel OpenMP dynamic run-time library accessible at run-time, you must specify the corresponding path:

1. Open the project's property pages in from the main menu: Project > Properties (or right click the Project name and select Properties).
2. Select Configuration Properties > Debugging > Environment
3. Enter the path to the Intel compiler libraries. For example, for an IA-32 architecture system, enter:

```
PATH=%PATH%;< Intel_compiler_installation_path>\IA32\Bin
```

Add the Intel OpenMP run-time library name to the linker options and exclude the default Microsoft OpenMP run-time library:

1. Open the project's property pages in from the main menu: Project > Properties (or right click the Project name and select Properties).
2. Select Configuration Properties > Linker > Command Line > Additional Options
3. Enter the OpenMP library name and the Visual C++ linker option `/nodefaultlib`:

Thread Affinity Interface (Linux* and Windows*)

The Intel® runtime library has the ability to bind OpenMP threads to physical processing units. The interface is controlled using the `KMP_AFFINITY` environment variable. Depending on the system (machine) topology, application, and operating system, thread affinity can have a dramatic effect on the application speed.

`Thread affinity` restricts execution of certain threads (virtual execution units) to a subset of the physical processing units in a multiprocessor computer. Depending upon the topology of the machine, thread affinity can have a dramatic effect on the execution speed of a program.

Thread affinity is supported on Windows OS systems and versions of Linux OS systems that have kernel support for thread affinity, but is not supported by Mac OS* X. The thread affinity interface is supported only for Intel® processors.

The Intel compiler's OpenMP runtime library has the ability to bind OpenMP threads to physical processing units. There are three types of interfaces you can use to specify this binding, which are collectively referred to as the Intel OpenMP Thread Affinity Interface:

- The high-level affinity interface uses an environment variable to determine the machine topology and assigns OpenMP threads to the processors based upon their physical location in the machine. This interface is controlled entirely by the KMP_AFFINITY environment variable.
- The mid-level affinity interface uses an environment variable to explicitly specifies which processors (labeled with integer IDs) are bound to OpenMP threads. This interface provides compatibility with the GNU gcc* GOMP_CPU_AFFINITY environment variable, but you can also invoke it by using the KMP_AFFINITY environment variable. The GOMP_CPU_AFFINITY environment variable is supported on Linux systems only, but users on Windows or Linux systems can use the similar functionality provided by the KMP_AFFINITY environment variable.
- The low-level affinity interface uses APIs to enable OpenMP threads to make calls into the OpenMP runtime library to explicitly specify the set of processors on which they are to be run. This interface is similar in nature to `sched_setaffinity` and related functions on Linux* systems or to `SetThreadAffinityMask` and related functions on Windows* systems. In addition, you can specify certain options of the KMP_AFFINITY environment variable to affect the behavior of the low-level API interface. For example, you can set the affinity type KMP_AFFINITY to disabled, which disables the low-level affinity interface, or you could use the KMP_AFFINITY or GOMP_CPU_AFFINITY environment variables to set the initial affinity mask, and then retrieve the mask with the low-level API interface.

The following terms are used in this section

- The total number of processing elements on the machine is referred to as the number of *`OS thread contexts.`*
- Each processing element is referred to as an Operating System processor, or *`OS proc`*.

- Each OS processor has a unique integer identifier associated with it, called an *OS proc ID*.
- The term *package* refers to a single or multi-core processor chip.
- The term *OpenMP Global Thread ID* (GTID) refers to an integer which uniquely identifies all threads known to the Intel OpenMP runtime library. The thread that first initializes the library is given GTID 0. In the normal case where all other threads are created by the library and when there is no nested parallelism, then *n-threads-var* - 1 new threads are created with GTIDs ranging from 1 to *ntheads-var* - 1, and each thread's GTID is equal to the OpenMP thread number returned by function `omp_get_thread_num()`. The high-level and mid-level interfaces rely heavily on this concept. Hence, their usefulness is limited in programs containing nested parallelism. The low-level interface does not make use of the concept of a GTID, and can be used by programs containing arbitrarily many levels of parallelism.

The KMP_AFFINITY Environment Variable

The `KMP_AFFINITY` environment variable uses the following general syntax:

Syntax
KMP_AFFINITY=[<*modifier*>,...]<*type*>[,<*permute*>][,<*offset*>]

For example, to list a machine topology map, specify `KMP_AFFINITY=verbose,none` to use a *modifier* of `verbose` and a *type* of `none`.

The following table describes the supported specific arguments.

Argument	**Default**	**Description**

modifier	`noverbose`
	`respect`
	`granularity=core`
		Optional. String consisting of keyword and specifier.
		• `granularity=`<*specifier*> takes the following specifiers: `fine`, `thread`, and `core`
		• `norespect`
		• `noverbose`
		• `nowarnings`
		• `proclist={`<*proc-list*>`}`
		• `respect`

Argument	Default	Description
		• verbose • warnings The syntax for <*proc-list*> is explained in mid-level affinity interface.
type	none	Required string. Indicates the thread affinity to use. • compact • disabled • explicit • none • scatter • logical (deprecated; instead use compact, but omit any permute value) • physical (deprecated; instead use scatter, possibly with an offset value) The logical and physical types are deprecated but supported for backward compatibility.
permute	0	Optional. Positive integer value. Not valid with type values of explicit, none, or disabled.

Argument	Default	Description
offset	0	Optional. Positive integer value. Not valid with type values of explicit, none, or disabled.

Affinity Types

Type is the only required argument.

type = none (default)

Does not bind OpenMP threads to particular thread contexts; however, if the operating system supports affinity, the compiler still uses the OpenMP thread affinity interface to determine machine topology. Specify KMP_AFFINITY=verbose,none to list a machine topology map.

type = compact

Specifying compact assigns the OpenMP thread <*n*>+1 to a free thread context as close as possible to the thread context where the <*n*> OpenMP thread was placed. For example, in a topology map, the nearer a node is to the root, the more significance the node has when sorting the threads.

type = disabled

Specifying disabled completely disables the thread affinity interfaces. This forces the OpenMP run-time library to behave as if the affinity interface was not supported by the operating system. This includes the low-level API interfaces such as kmp_set_affinity and kmp_get_affinity, which have no effect and will return a nonzero error code.

type = explicit

Specifying explicit assigns OpenMP threads to a list of OS proc IDs that have been explicitly specified by using the proclist= modifier, which is required for this affinity type. See Explicitly Specifying OS Proc IDs (GOMP_CPU_AFFINITY).

type = scatter

Specifying scatter distributes the threads as evenly as possible across the entire system. scatter is the opposite of compact; so the leaves of the node are most significant when sorting through the machine topology map.

Deprecated Types: logical and physical

Types `logical` and `physical` are deprecated and may become unsupported in a future release. Both are supported for backward compatibility.

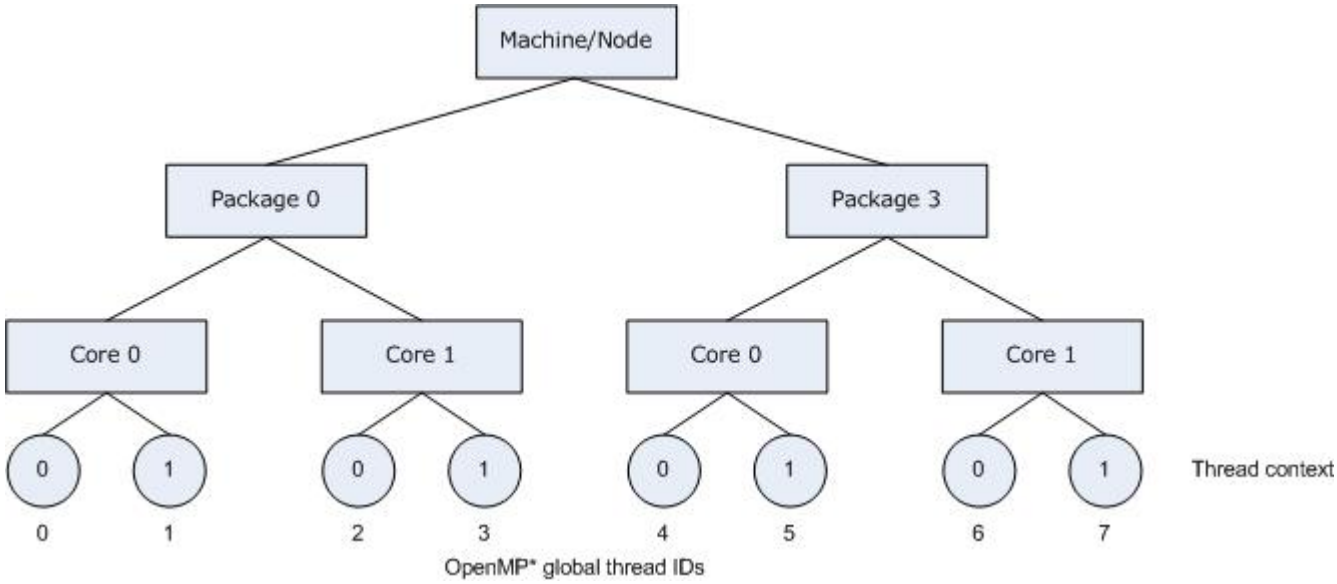
For `logical` and `physical` affinity types, a single trailing integer is interpreted as an `offset` specifier instead of a `permute` specifier. In contrast, with `compact` and `scatter` types, a single trailing integer is interpreted as a `permute` specifier.

- Specifying `logical` assigns OpenMP threads to consecutive logical processors, which are also called hardware thread contexts. The type is equivalent to `compact`, except that the `permute` specifier is not allowed. Thus, `KMP_AFFINITY=logical,n` is equivalent to `KMP_AFFINITY=compact,0,n` (this equivalence is true regardless of the whether or not a `granularity=fine` modifier is present).
- Specifying `physical` assigns threads to consecutive physical processors (cores). For systems where there is only a single thread context per core, the type is equivalent to `logical`. For systems where multiple thread contexts exist per core, `physical` is equivalent to `compact` with a `permute` specifier of 1; that is, `KMP_AFFINITY=physical,n` is equivalent to `KMP_AFFINITY=compact,1,n` (regardless of the whether or not a `granularity=fine` modifier is present). This equivalence means that when the compiler sorts the map it should permute the innermost level of the machine topology map to the outermost, presumably the thread context level. This type does not support the `permute` specifier.

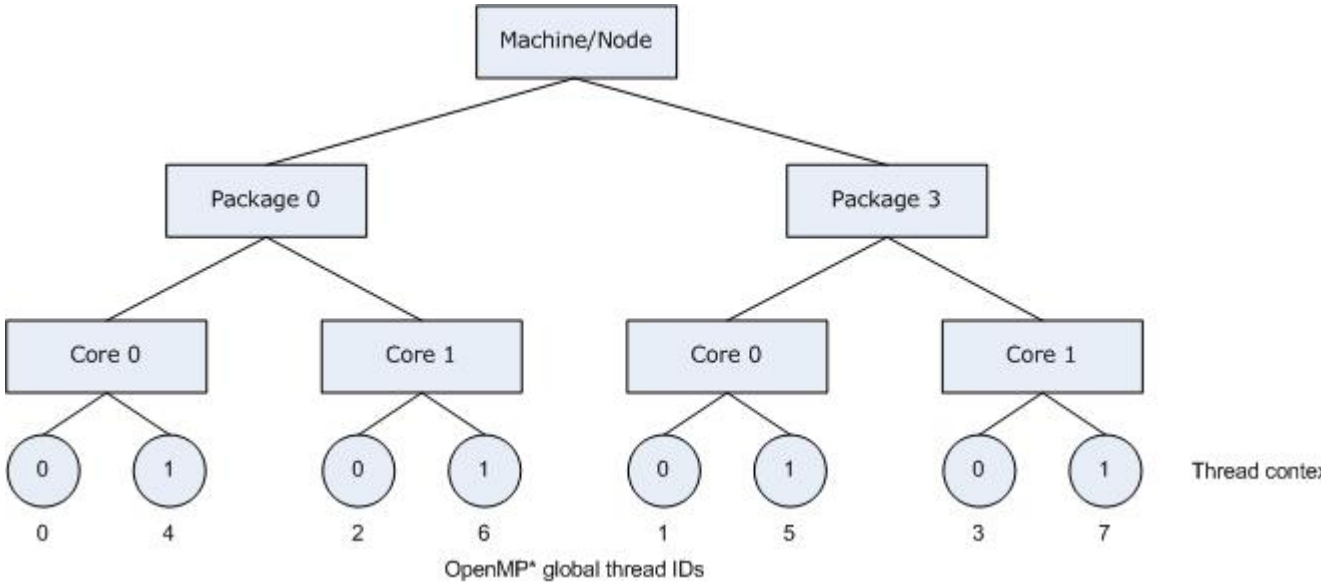
Examples of Types `compact` and `scatter`

The following figure illustrates the topology for a machine with two processors, and each processor has two cores; further, each core has Hyper-Threading Technology (HT Technology) enabled.

The following figure also illustrates the binding of OpenMP thread to hardware thread contexts when specifying `KMP_AFFINITY=granularity=fine,compact`.



Specifying `scatter` on the same system as shown in the figure above, the OpenMP threads would be assigned the thread contexts as shown in the following figure, which shows the result of specifying `KMP_AFFINITY=granularity=fine,scatter`.



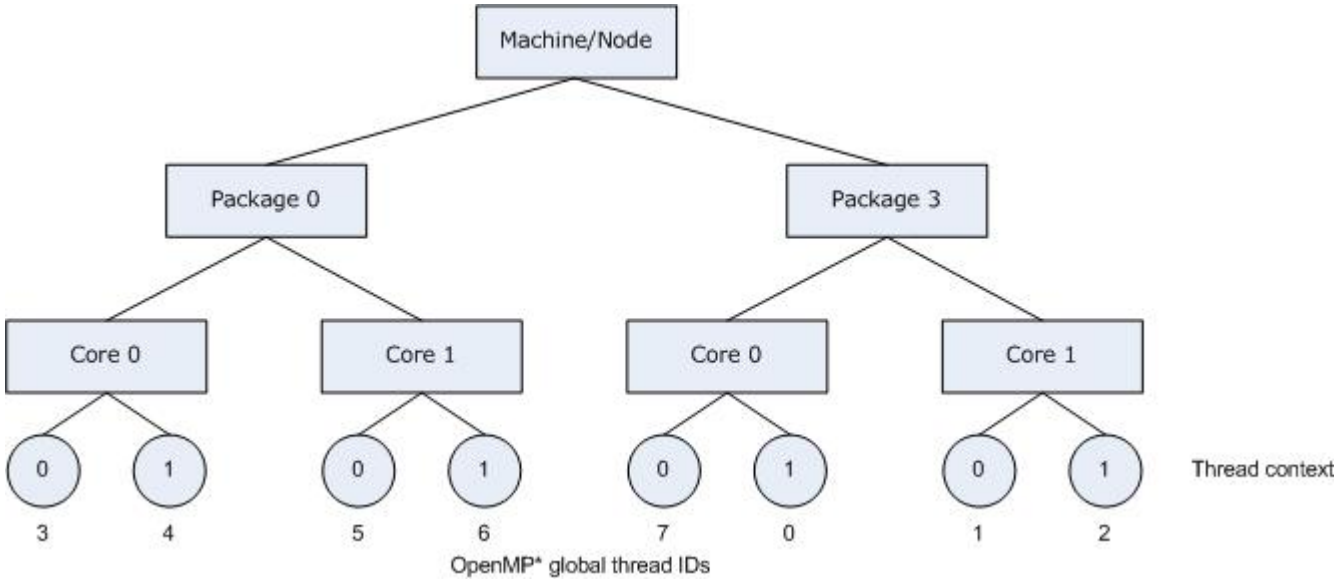
permute and offset combinations

For both `compact` and `scatter`, `permute` and `offset` are allowed; however, if you specify only one integer, the compiler interprets the value as a permute specifier. Both `permute` and `offset` default to 0.

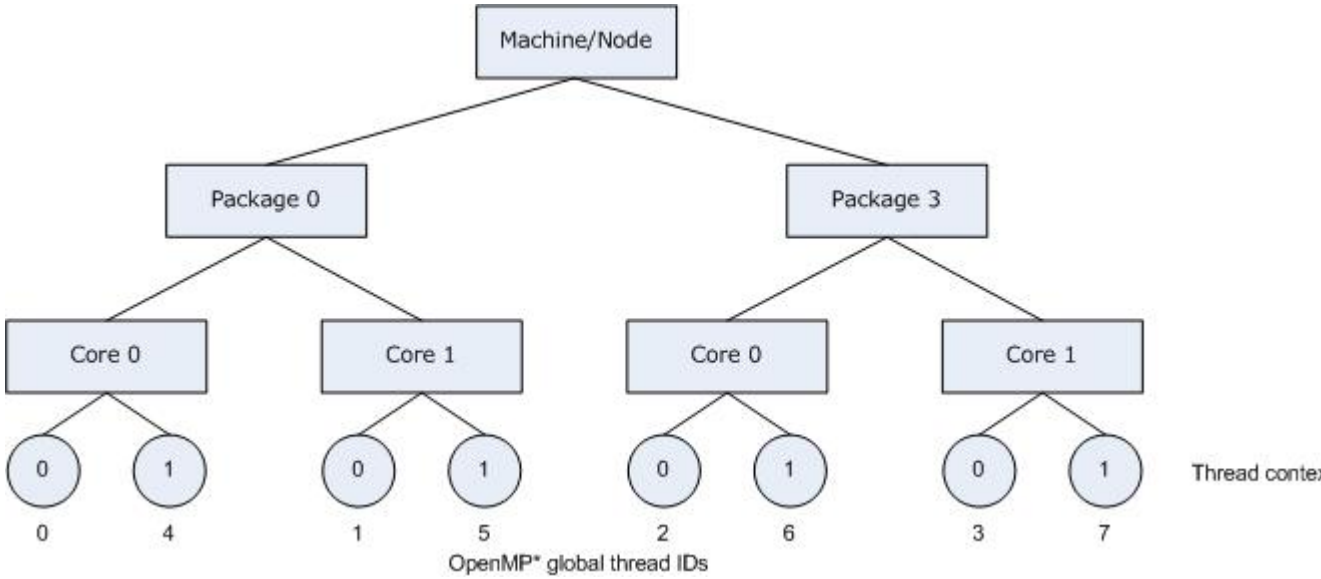
The `permute` specifier controls which levels are most significant when sorting the machine topology map. A value for permute forces the mappings to make the specified number of most significant levels of the sort the least significant, and it inverts the order of significance. The root node of the tree is not considered a separate level for the sort operations.

The `offset` specifier indicates the starting position for thread assignment.

The following figure illustrates the result of specifying `KMP_AFFINITY=granularity=fine,compact,0,3`.



Consider the hardware configuration from the previous example, running an OpenMP application which exhibits data sharing between consecutive iterations of loops. We would therefore like consecutive threads to be bound close together, as is done with `KMP_AFFINITY=compact`, so that communication overhead, cache line invalidation overhead, and page thrashing are minimized. Now, suppose the application also had a number of parallel regions which did not utilize all of the available OpenMP threads. It is desirable to avoid binding multiple threads to the same core and leaving other cores not utilized, since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core. Since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core, you might want to avoid binding multiple threads to the same core while leaving other cores unused. The following figure illustrates this strategy of using `KMP_AFFINITY=granularity=fine,compact,1,0` as a setting.



The OpenMP thread *n*+1 is bound to a thread context as close as possible to OpenMP thread *n*, but on a different core. Once each core has been assigned one OpenMP thread, the subsequent OpenMP threads are assigned to the available cores in the same order, but they are assigned on different thread contexts.

Modifier Values for Affinity Types

Modifiers are optional arguments that precede type. If you do not specify a modifier, the `noverbose`, `respect`, and `granularity=core` modifiers are used automatically.

Modifiers are interpreted in order from left to right, and can negate each other. For example, specifying `KMP_AFFINITY=verbose,noverbose,scatter` is therefore equivalent to setting `KMP_AFFINITY=noverbose,scatter`, or just `KMP_AFFINITY=scatter`.

modifier = noverbose (default)

Does not print verbose messages.

modifier = verbose

Prints messages concerning the supported affinity. The messages include information about the number of packages, number of cores in each package, number of thread contexts for each core, and OpenMP thread bindings to physical thread contexts.

Information about binding OpenMP threads to physical thread contexts is indirectly shown in the form of the mappings between hardware thread contexts and the operating system (OS) processor (proc) IDs. The affinity mask for each OpenMP thread is printed as a set of OS processor IDs.

For example, specifying `KMP_AFFINITY=verbose,scatter` on a dual core system with two processors, with Hyper-Threading Technology (HT Technology) disabled, results in a message listing similar to the following when then program is executed:

Verbose, scatter message

```
...
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
{0,1,2,3}
KMP_AFFINITY: 4 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0]
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 [thread 0]
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 [thread 0]
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 [thread 0]
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {1}
```

The verbose modifier generates several standard, general messages. The following table summarizes how to read the messages.

Message String	Description
"affinity capable"	Indicates that all components (compiler, operating system, and hardware) support affinity, so thread binding is possible.

Message String	Description
"using global cpuid info"	Indicates that the machine topology was discovered by binding a thread to each operating system processor and decoding the output of the `cpuid` instruction.
"using local cpuid info"	Indicates that compiler is decoding the output of the `cpuid` instruction, issued by only the initial thread, and is assuming a machine topology using the number of operating system processors.
"using /proc/cpuinfo"	Linux* only. Indicates that `cpuinfo` is being used to determine machine topology.
"using flat"	Operating system processor ID is assumed to be equivalent to physical package ID. This method of determining machine topology is used if none of the other methods will work, but may not accurately detect the actual machine topology.
"uniform topology of"	The machine topology map is a full tree with no missing leaves at any level.

The mapping from the operating system processors to thread context ID is printed next. The binding of OpenMP thread context ID is printed next unless the affinity type is `none`. The thread level is contained in brackets (in the listing shown above). This implies that there is no representation of the thread context level in the machine topology map. For more information, see Determining Machine Topology.

modifier = granularity

Binding OpenMP threads to particular packages and cores will often result in a performance gain on systems with Intel processors with Hyper-Threading Technology (HT Technology) enabled; however, it is usually not beneficial to bind each OpenMP thread to a particular thread context on a specific core. Granularity describes the lowest levels that OpenMP threads are allowed to float within a topology map.

This modifier supports the following additional specifiers.

Specifier	Description
`core`	Default. Broadest granularity level supported. Allows all the OpenMP threads bound to a core to float between the different thread contexts.
`fine` or `thread`	The finest granularity level. Causes each OpenMP thread to be bound to a single thread context. The two specifiers are functionally equivalent.

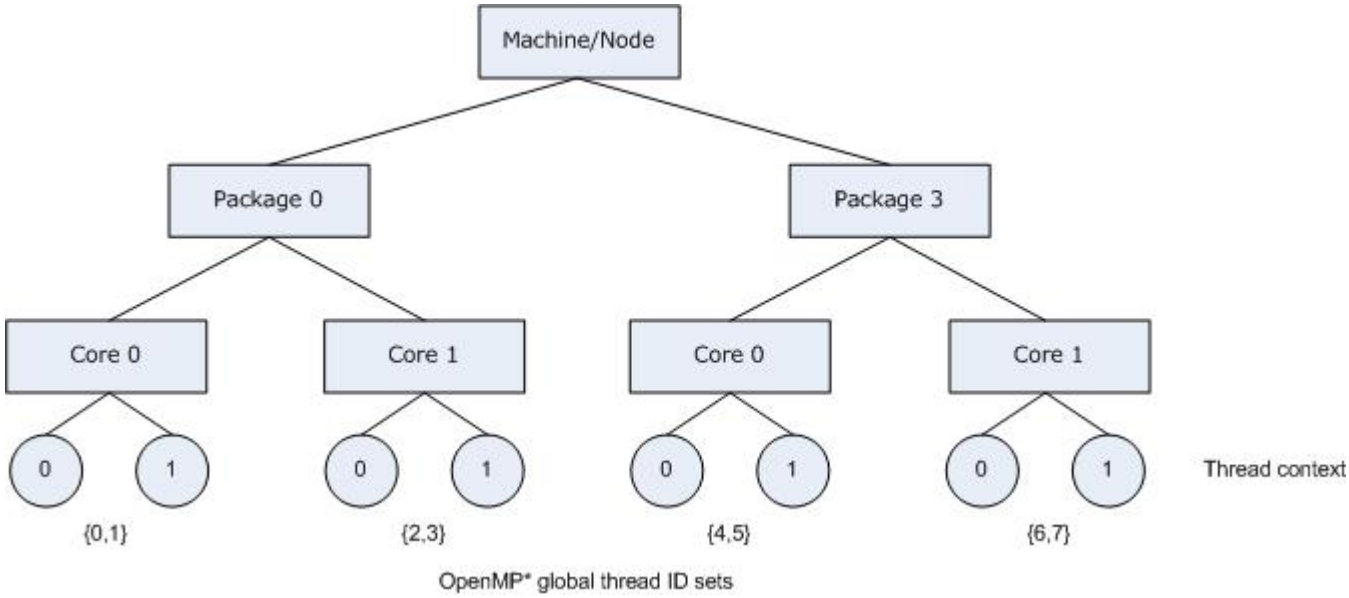
Specifying `KMP_AFFINITY=verbose,granularity=core,compact` on the same dual core system with two processors as in the previous section, but with HT Technology enabled, results in a message listing similar to the following when the program is executed:

Verbose, granularity=core,compact message

```
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
{0,1,2,3,4,5,6,7}
KMP_AFFINITY: 8 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to package 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to package 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 thread 0
KMP_AFFINITY: OS proc 5 maps to package 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to package 3 core 1 thread 1
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0,4}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {0,4}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2,6}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {2,6}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {1,5}
KMP_AFFINITY: Internal thread 5 bound to OS proc set {1,5}
KMP_AFFINITY: Internal thread 6 bound to OS proc set {3,7}
KMP_AFFINITY: Internal thread 7 bound to OS proc set {3,7}
```

The affinity mask for each OpenMP thread is shown in the listing (above) as the set of operating system processor to which the OpenMP thread is bound.

The following figure illustrates the machine topology map, for the above listing, with OpenMP thread bindings.



In contrast, specifying `KMP_AFFINITY=verbose,granularity=fine,compact` or `KMP_AFFINITY=verbose,granularity=thread,compact` binds each OpenMP thread to a single hardware thread context when the program is executed:

Verbose, granularity=fine,compact message

```
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
{0,1,2,3,4,5,6,7}
KMP_AFFINITY: 8 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to package 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to package 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 thread 0
KMP_AFFINITY: OS proc 5 maps to package 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to package 3 core 1 thread 1
KMP_AFFINITY: Internal thread 0 bound to OS proc set {0}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {4}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {2}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {6}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {1}
KMP_AFFINITY: Internal thread 5 bound to OS proc set {5}
KMP_AFFINITY: Internal thread 6 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 7 bound to OS proc set {7}
```

The OpenMP to hardware context binding for this example was illustrated in the first example.

Specifying `granularity=fine` will always cause each OpenMP thread to be bound to a single OS processor. This is equivalent to `granularity=thread`, currently the finest granularity level.

modifier = respect (default)

Respect the process' original affinity mask, or more specifically, the affinity mask in place for the thread that initializes the OpenMP run-time library. The behavior differs between Linux and Windows OS:

- On Windows: Respect original affinity mask for the process.
- On Linux: Respect the affinity mask for the thread that initializes the OpenMP run-time library.

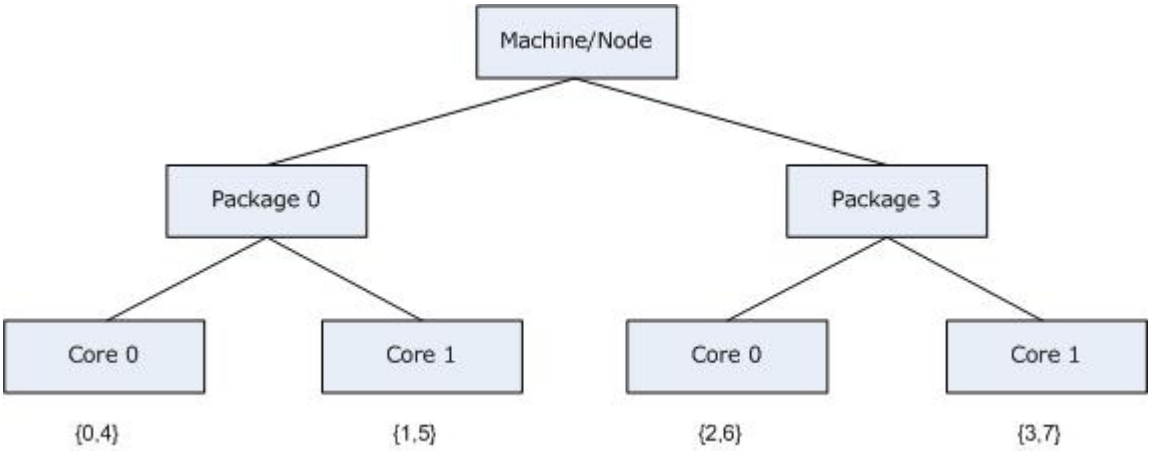
Specifying `KMP_AFFINITY=verbose,compact` for the same system used in the previous example, with HT Technology enabled, and invoking the library with an initial affinity mask of {4,5,6,7} (thread context 1 on every core) causes the compiler to model the machine as a dual core, two-processor system with HT Technology disabled.

Verbose,compact message

```
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected:
{4,5,6,7}
KMP_AFFINITY: 4 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 4 maps to package 0 core 0 [thread 1]
KMP_AFFINITY: OS proc 6 maps to package 0 core 1 [thread 1]
KMP_AFFINITY: OS proc 5 maps to package 3 core 0 [thread 1]
KMP_AFFINITY: OS proc 7 maps to package 3 core 1 [thread 1]
KMP_AFFINITY: Internal thread 0 bound to OS proc set {4}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {6}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {5}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {7}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {4}
KMP_AFFINITY: Internal thread 5 bound to OS proc set {6}
KMP_AFFINITY: Internal thread 6 bound to OS proc set {5}
KMP_AFFINITY: Internal thread 7 bound to OS proc set {7}
```

Because there are eight thread contexts on the machine, by default the compiler created eight threads for an OpenMP `parallel` construct.

The brackets around thread 1 indicate that the thread context level is ignored, and is not present in the topology map. The following figure illustrates the corresponding machine topology map.



OpenMP* global thread ID sets

When using the local `cpuid` information to determine the machine topology, it is not always possible to distinguish between a machine that does not support Hyper-Threading Technology (HT Technology) and a machine that supports it, but has it disabled. Therefore, the compiler does not include a level in the map if the elements (nodes) at that level had no siblings, with the exception that the package level is always modeled. As mentioned earlier, the package level will always appear in the topology map, even if there only a single package in the machine.

modifier = norespect

Do not respect original affinity mask for the process. Binds OpenMP threads to all operating system processors.

In early versions of the OpenMP run-time library that supported only the `physical` and `logical` affinity types, `norespect` was the default and was not recognized as a modifier.

The default was changed to `respect` when types `compact` and `scatter` were added; therefore, thread bindings for the `logical` and `physical` affinity types may have changed with the newer compilers in situations where the application specified a partial initial thread affinity mask.

modifier = nowarnings

Do not print warning messages from the affinity interface.

modifier = warnings (default)

Print warning messages from the affinity interface (default).

Determining Machine Topology

On IA-32 and Intel® 64 architecture systems, if the package has an APIC (Advanced Programmable Interrupt Controller), the compiler will use the `cpuid` instruction to obtain the `package id`, `core id`, and `thread context id`. Under normal conditions, each thread context on the system is assigned a unique APIC ID at boot time. The compiler obtains other pieces of information obtained by using the *`cpuid`* instruction, which together with the number of OS thread contexts (total number of processing elements on the machine), determine how to break the APIC ID down into the `package ID`, `core ID`, and `thread context ID`.

Normally, all `core ids` on a package and all `thread context ids` on a core are contiguous; however, numbering assignment gaps are common for `package ids`, as shown in the figure above.

On IA-64 architecture systems on Linux* operating systems, the compiler obtains this information from `/proc/cpuinfo`. The `package id`, `core id`, and `thread context id` are obtained from the `physical id`, `core id`, and `thread id` fields from `/proc/cpuinfo`. The `core id` and `thread context id` default to 0, but the `physical id` field must be present in order to determine the machine topology, which is not always the case. If the information contained in `/proc/cpuinfo` is insufficient or erroneous, you may create an alternate specification file and pass it to the OpenMP runtime library by using the KMP_CPUINFO_FILE environment variable, as described in KMP_CPUINFO and /proc/cpuinfo.

If the compiler cannot determine the machine topology using either method, but the operating system supports affinity, a warning message is printed, and the topology is assumed to be `flat`. For example, a flat topology assumes the operating system process *`N`* maps to package *`N`*, and there exists only one thread context per core and only one core for each package. (This assumption is always the case for processors based on IA-64 architecture running Windows.)

If the machine topology cannot be accurately determined as described above, the user can manually copy `/proc/cpuinfo` to a temporary file, correct any errors, and specify the machine topology to the OpenMP runtime library via the environment variable `KMP_CPUINFO_FILE=<temp_filename>`, as described in the section KMP_CPUINFO_FILE and /proc/cpuinfo.

Regardless of the method used in determining the machine topology, if there is only one thread context per core for every core on the machine, the thread context level will not appear in the topology map. If there is only one core per package for every package in the machine, the core level will not appear in the machine topology map. The topology map need not be a full tree, because different packages may contain a different number of cores, and different cores may support a different number of thread contexts.

The package level will always appear in the topology map, even if there only a single package in the machine.

KMP_CPUINFO and /proc/cpuinfo

One of the methods the Intel compiler OpenMP runtime library can use to detect the machine topology on Linux* systems is to parse the contents of `/proc/cpuinfo`. If the contents of this file (or a device mapped into the Linux file system) are insufficient or erroneous, you can consider copying its contents to a writable temporary file <*`temp_file`*>,correct it or extend it with the necessary information, and set KMP_CPUINFO_FILE=<*`temp_file`*>.

If you do this, the OpenMP runtime library will read the <*`temp_file`*> location pointed to by KMP_CPUINFO_FILE instead of the information contained in `/proc/cpuinfo` or attempting to detect the machine topology by decoding the APIC IDs. That is, the information contained in the <*`temp_file`*> overrides these other methods. You can use the KMP_CPUINFO_FILE interface on Windows* systems, where `/proc/cpuinfo` does not exist.

The content of `/proc/cpuinfo` or <*`temp_file`*> should contain a list of entries for each processing element on the machine. Each processor element contains a list of entries (descriptive name and value on each line). A blank line separates the entries for each processor element. Only the following fields are used to determine the machine topology from each entry, either in <*`temp_file`*> or `/proc/cpuinfo`:

Field	Description
processor :	Specifies the OS ID for the processing element. The OS ID must be unique. The `processor` and `physical id` fields are the only ones that are required to use the interface.
physical id :	Specifies the package ID, which is a physical chip ID. Each package may contain multiple cores. The package level always exists in the Intel compiler OpenMP run-time library's model of the machine topology.
core id :	Specifies the core ID. If it does not exist, it defaults to 0. If every package on the machine contains only a single core, the core

Field	Description
	level will not exist in the machine topology map (even if some of the core ID fields are non-zero).
thread id :	Specifies the thread ID. If it does not exist, it defaults to 0. If every core on the machine contains only a single thread, the thread level will not exist in the machine topology map (even if some thread ID fields are non-zero).
node_*n* id :	This is a extension to the normal contents of `/proc/cpuinfo` that can be used to specify the nodes at different levels of the memory interconnect on Non-Uniform Memory Access (NUMA) systems. Arbitrarily many levels *n* are supported. The node_0 level is closest to the package level; multiple packages comprise a node at level 0. Multiple nodes at level 0 comprise a node at level 1, and so on.

Each entry must be spelled exactly as shown, in lowercase, followed by optional whitespace, a colon (:), more optional whitespace, then the integer ID. Fields other than those listed are simply ignored.

NOTE. It is common for the `thread id` field to be missing from `/proc/cpuinfo` on many Linux variants, and for a field labeled `siblings` to specify the number of threads per node or number of nodes per package. However, the Intel compiler OpenMP runtime library ignores fields labeled `siblings` so it can distinguish between the `thread id` and `siblings` fields. When this situation arises, the warning message `Physical node/pkg/core/thread ids not unique` appears (unless the `type specified is nowarnings`).

The following is a sample entry for an IA-64 architecture system that has been extended to model the different levels of the memory interconnect:

Sample `/proc/cpuinfo` **or <*temp-file*>**

```
processor : 23
vendor : GenuineIntel
arch : IA-64
family : 32
model : 0
revision : 7
archrev : 0
features : branchlong, 16-byte atomic ops
cpu number : 0
cpu regs : 4
cpu MHz : 1594.000007
itc MHz : 399.000000
BogoMIPS : 3186.68
siblings : 2
node_3 id : 0
node_2 id : 1
node_1 id : 0
node_0 id : 1
physical id : 2563
core id: 1
thread id: 0
```

This example includes the fields from `/proc/cpuinfo` that affect the functionality of the Intel compiler OpenMP Affinity Interface: `processor`, `physical id`, `core id`, and `thread id`. Other fields (`vendor`, `arch`, ..., `siblings`) from `/proc/cpuinfo` are ignored. The four fields `node_n` are extensions.

Explicitly Specifying OS Processor IDs (GOMP_CPU_AFFINITY)

Instead of allowing the library to detect the hardware topology and automatically assign OpenMP threads to processing elements, the user may explicitly specify the assignment by using a list of operating system (OS) processor (proc) IDs. However, this requires knowledge of which processing elements the OS proc IDs represent.

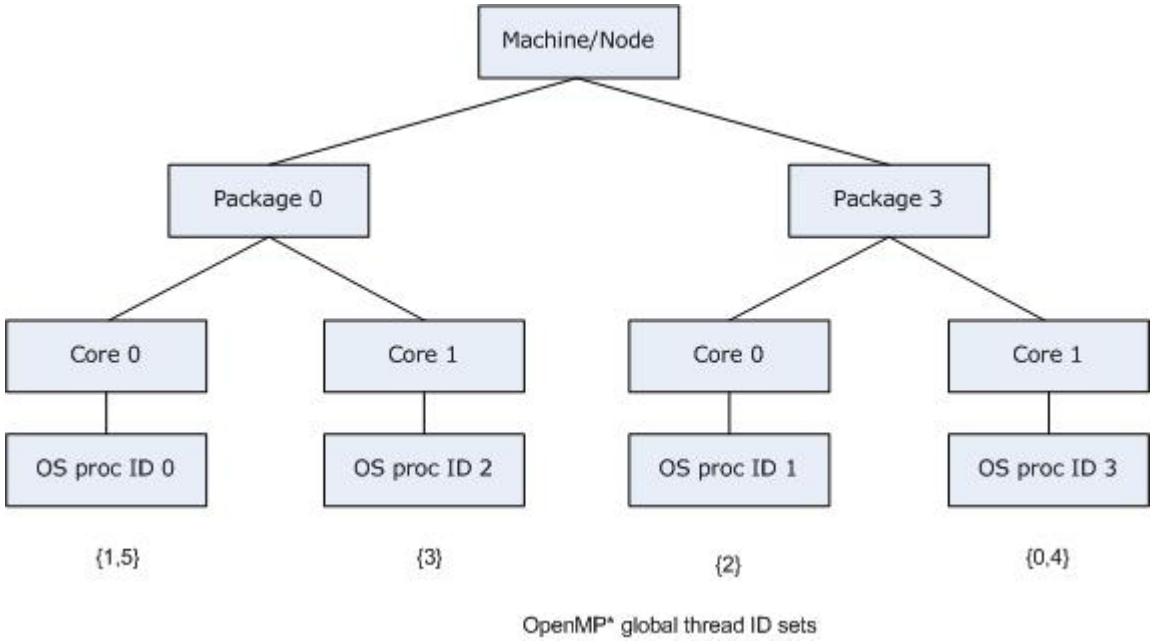
This list may either be specified by using the proclist modifier along with the explicit affinity type in the KMP_AFFINITY environment variable, or by using the GOMP_CPU_AFFINITY environment variable (for compatibility with `gcc`) when using the Intel OpenMP compatibility libraries.

On Linux systems when using the Intel OpenMP compatibility libraries enabled by the compiler option `-openmp-lib compat`, you can use the GOMP_CPU_AFFINITY environment variable to specify a list of OS processor IDs. Its syntax is identical to that accepted by `libgomp` (assume that <*proc_list*> produces the entire GOMP_CPU_AFFINITY environment string):

<*proc_list*> :=	<entry> | <*elem*> , <list> | <elem> <whitespace> <list>
<*elem*> :=	<*proc_spec*> | <*range*>
<*proc_spec*> :=	<*proc_id*>
<*range*> :=	<*proc_id*> - <*proc_id*> | <*proc_id*> - <*proc_id*> : <int>
<*proc_id*> :=	<positive_int>

OS processors specified in this list are then assigned to OpenMP threads, in order of OpenMP Global Thread IDs. If more OpenMP threads are created than there are elements in the list, then the assignment occurs modulo the size of the list. That is, OpenMP Global Thread ID *n* is bound to list element *n* mod <*list_size*>.

Consider the machine previously mentioned: a dual core, dual-package machine without Hyper-Threading Technology (HT Technology) enabled, where the OS proc IDs are assigned in the same manner as the example in a previous figure. Suppose that the application creates 6 OpenMP threads instead of 4 (the default), oversubscribing the machine. If `GOMP_CPU_AFFINITY=3,0-2`, then OpenMP threads are bound as shown in the figure below, just as should happen when compiling with `gcc` and linking with `libgomp`:



OpenMP* global thread ID sets

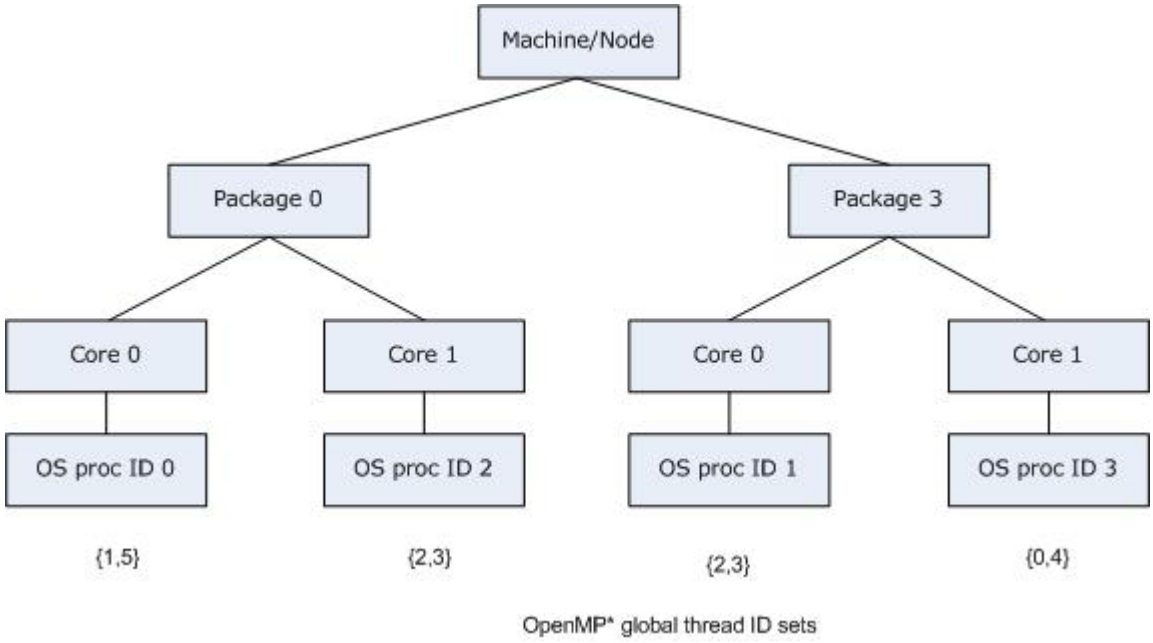
The same syntax can be used to specify the OS proc ID list in the proclist=[<proc_list>] modifier in the KMP_AFFINITY environment variable string. There is a slight difference: in order to have strictly the same semantics as in the `gcc` OpenMP runtime library `libgomp`: the GOMP_CPU_AFFINITY environment variable implies `granularity=fine`. If you specify the OS proc list in the KMP_AFFINITY environment variable without a `granularity=` specifier, then the default `granularity` is not changed. That is, OpenMP threads are allowed to float between the different thread contexts on a single core. Thus GOMP_CPU_AFFINITY=`<proc_list>` is an alias for KMP_AFFINITY=`granularity=fine,proclist=[<proc_list>],explicit`

In the KMP_AFFINITY environment variable string, the syntax is extended to handle operating system processor ID sets. The user may specify a set of operating system processor IDs among which an OpenMP thread may execute ("œfloat") enclosed in brackets:

<*proc_list*> :=	<proc_id> | { <float_list> }
<*float_list*> :=	<proc_id> | <proc_id> , <float_list>

This allows functionality similarity to the `granularity= specifier`, but it is more flexible. The OS processors on which an OpenMP thread executes may exclude other OS processors nearby in the machine topology, but include other distant OS processors. Building upon the

previous example, we may allow OpenMP threads 2 and 3 to "œfloat" between OS processor 1 and OS processor 2 by using KMP_AFFINITY="`granularity=fine,proclist=[3,0,{1,2},{1,2}],explicit`", as shown in the figure below:



If `verbose` were also specified, the output when the application is executed would include:

```
KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"
KMP_AFFINITY: Affinity capable, using global cpuid info
KMP_AFFINITY: Initial OS proc set respected: {0,1,2,3}
KMP_AFFINITY: 4 available OS procs - Uniform topology of
KMP_AFFINITY: 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map ([] => level not in map):
KMP_AFFINITY: OS proc 0 maps to package 0 core 0 [thread 0]
KMP_AFFINITY: OS proc 2 maps to package 0 core 1 [thread 0]
KMP_AFFINITY: OS proc 1 maps to package 3 core 0 [thread 0]
KMP_AFFINITY: OS proc 3 maps to package 3 core 1 [thread 0]
KMP_AFFINITY: Internal thread 0 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 1 bound to OS proc set {0}
KMP_AFFINITY: Internal thread 2 bound to OS proc set {1,2}
KMP_AFFINITY: Internal thread 3 bound to OS proc set {1,2}
KMP_AFFINITY: Internal thread 4 bound to OS proc set {3}
KMP_AFFINITY: Internal thread 5 bound to OS proc set {0}}
```

Low Level Affinity API

Instead of relying on the user to specify the OpenMP thread to OS proc binding by setting an environment variable before program execution starts (or by using the `kmp_settings` interface before the first parallel region is reached), each OpenMP thread may determine the desired set of OS procs on which it is to execute and bind to them with the `kmp_set_affinity` API call.

The Fortran API interfaces follow, where the type name `kmp_affinity_mask_t` is defined in `omp.h` or `omp.mod`:

Syntax	Description
`integer function kmp_set_affinity(mask) integer (kind=kmp_affinity_mask_kind) mask`	Sets the affinity mask for the current OpenMP thread to `mask`, where `mask` is a set of OS proc IDs that has been created using the API calls listed below, and the thread will only execute on OS procs in the set. Returns either a zero (0) upon success or a nonzero error code.
`integer kmp_get_affinity(mask) integer (kind=kmp_affinity_mask_kind) mask`	Retrieves the affinity mask for the current OpenMP thread, and stores it in `mask`, which must have previously been initialized with a call to `kmp_create_affinity_mask()`. Returns either a zero (0) upon success or a nonzero error code.
`integer function kmp_get_affinity_max_proc()`	Returns the maximum OS proc ID that is on the machine, plus 1. All OS proc IDs are guaranteed to be between 0 (inclusive) and `kmp_get_affinity_max_proc()` (exclusive).
`subroutine kmp_create_affinity_mask(mask) integer (kind=kmp_affinity_mask_kind) mask`	Allocates a new OpenMP thread affinity mask, and initializes `mask` to the empty set of OS procs. The implementation is free to use an object of `kmp_affinity_mask_t` either as the set itself, a pointer to the actual set, or an index into a table describing the set. Do not make any assumption as to what the actual representation is.
`subroutine kmp_destroy_affinity_mask(mask) integer (kind=kmp_affinity_mask_kind) mask`	Deallocates the OpenMP thread affinity mask. For each call to `kmp_create_affinity_mask()`, there should be a corresponding call to `kmp_destroy_affinity_mask()`.
`integer function kmp_set_affinity_mask_proc(proc, mask)`	Adds the OS proc ID proc to the set `mask`, if it is not already. Returns either a zero (0) upon success or a nonzero error code.

Syntax	Description

`integer proc`
`integer`
`(kind=kmp_affinity_mask_kind) mask`	

`integer function`
`kmp_unset_affinity_mask_proc(proc,`
`mask)`
`integer proc`
`integer`
`(kind=kmp_affinity_mask_kind) mask`
	If the OS proc ID proc is in the set `mask`, it removes it. Returns either a zero (0) upon success or a nonzero error code.

`integer function`
`kmp_get_affinity_mask_proc(proc,`
`mask)integer proc`
`integer`
`(kind=kmp_affinity_mask_kind) mask`
	Returns 1 if the OS proc ID proc is in the set `mask`; if not, it returns 0.

Once an OpenMP thread has set its own affinity mask via a successful call to `kmp_affinity_set_mask()`, then that thread remains bound to the corresponding OS proc set until at least the end of the parallel region, unless reset via a subsequent call to `kmp_affinity_set_mask()`.

Between parallel regions, the affinity mask (and the corresponding OpenMP thread to OS proc bindings) can be considered thread private data objects, and have the same persistence as described in the OpenMP Application Program Interface. For more information, see the OpenMP API specification (http://www.openmp.org), some relevant parts of which are provided below:

"In order for the affinity mask and thread binding to persist between two consecutive active parallel regions, all three of the following conditions must hold:

- Neither parallel region is nested inside another explicit parallel region.
- The number of threads used to execute both parallel regions is the same.
- The value of the dyn-var internal control variable in the enclosing task region is false at entry to both parallel regions."

Therefore, by creating a parallel region at the start of the program whose sole purpose is to set the affinity mask for each thread, the user can mimic the behavior of the KMP_AFFINITY environment variable with low-level affinity API calls, if program execution obeys the three aforementioned rules from the OpenMP specification. Consider again the example presented

in the previous figure. To mimic KMP_AFFINITY=compact, in each OpenMP thread with global thread ID n, we need to create an affinity mask containing OS proc IDs n modulo c, n modulo c + c, and so on, where c is the number of cores. This can be accomplished by inserting the following C code fragment into the application that gets executed at program startup time:

Example

```
int main() {
#pragma omp parallel
{
int tmax = omp_get_max_threads();
int tnum = omp_get_thread_num();
int nproc = omp_get_num_procs();
int ncores = nproc / 2;
int i;
kmp_affinity_mask_t mask;
kmp_create_affinity_mask(&mask);
for (i = tnum % ncores; i < tmax; i += ncores) {
kmp_set_affinity_mask_proc(i, &mask);
}
if (kmp_set_affinity(&mask) != 0) <error>;
}
```

This program fragment was written with knowledge about the mapping of the OS proc IDs to the physical processing elements of the target machine. On another machine, or on the same machine with a different OS installed, the program would still run, but the OpenMP thread to physical processing element bindings could differ.

Using Parallelism: Automatic Parallelization

27

Auto-parallelization Overview

The auto-parallelization feature of the Intel® compiler automatically translates serial portions of the input program into equivalent multithreaded code. Automatic parallelization determines the loops that are good worksharing candidates, performs the dataflow analysis to verify correct parallel execution, and partitions the data for threaded code generation as needed in programming with OpenMP* directives. The OpenMP and auto-parallelization applications provide the performance gains from shared memory on multiprocessor and dual core systems.

The auto-parallelization feature of the Intel® compiler automatically translates serial portions of the input program into equivalent multithreaded code. The auto-parallelizer analyzes the dataflow of the loops in the application source code and generates multithreaded code for those loops which can safely and efficiently be executed in parallel.

This behavior enables the potential exploitation of the parallel architecture found in symmetric multiprocessor (SMP) systems.

Automatic parallelization frees developers from having to:

- find loops that are good worksharing candidates
- perform the dataflow analysis to verify correct parallel execution
- partition the data for threaded code generation as is needed in programming with OpenMP* directives.

The parallel run-time support provides the same run-time features as found in OpenMP, such as handling the details of loop iteration modification, thread scheduling, and synchronization.

While OpenMP directives enable serial applications to transform into parallel applications quickly, a programmer must explicitly identify specific portions of the application code that contain parallelism and add the appropriate compiler directives.

Auto-parallelization, which is triggered by the `-parallel` (Linux* OS and Mac OS* X) or `/Qparallel` (Windows* OS) option, automatically identifies those loop structures that contain parallelism. During compilation, the compiler automatically attempts to deconstruct the code sequences into separate threads for parallel processing. No other effort by the programmer is needed.

NOTE. IA-64 architecture only: Specifying these options implies `-opt-mem-bandwith1` (Linux) or `/Qopt-mem-bandwidth1` (Windows).

Serial code can be divided so that the code can execute concurrently on multiple threads. For example, consider the following serial code example.

Example 1: Original Serial Code

```
subroutine ser(a, b, c)
  integer, dimension(100) :: a, b, c
  do i=1,100
    a(i) = a(i) + b(i) * c(i)
  enddo
end subroutine ser
```

The following example illustrates one method showing how the loop iteration space, shown in the previous example, might be divided to execute on two threads.

Example 2: Transformed Parallel Code

```
subroutine par(a, b, c)
  integer, dimension(100) :: a, b, c
  ! Thread 1
  do i=1,50
    a(i) = a(i) + b(i) * c(i)
  enddo
  ! Thread 2
  do i=51,100
    a(i) = a(i) + b(i) * c(i)
  enddo
end subroutine par
```

Auto-Vectorization and Parallelization

Auto-vectorization detects low-level operations in the program that can be done in parallel, and then converts the sequential program to process 2, 4, 8 or up to 16 elements in one operation, depending on the data type. In some cases auto-parallelization and vectorization

can be combined for better performance results. For example, in the code below, thread-level parallelism can be exploited in the outermost loop, while instruction-level parallelism can be exploited in the innermost loop.

Example

```
DO I = 1, 100     ! Execute groups of iterations in different hreads (TLP)
  DO J = 1, 32    ! Execute in SIMD style with multimedia extension (ILP)
     A(J,I) = A(J,I) + 1
  ENDDO
ENDDO
```

Auto-vectorization can help improve performance of an application that runs on systems based on Pentium®, Pentium with MMX™ technology, Pentium II, Pentium III, and Pentium 4 processors.

With the right choice of options, you can:

- Increase the performance of your application with minimum effort
- Use compiler features to develop multithreaded programs faster

Additionally, with the relatively small effort of adding OpenMP directives to existing code you can transform a sequential program into a parallel program. The following example shows OpenMP directives within the code.

Example

```
!OMP$ PARALLEL PRIVATE(NUM), SHARED (X,A,B,C)
! Defines a parallel region
```

Example

```
!OMP$ PARALLEL DO
! Specifies a parallel region that
! implicitly contains a single DO directive
DO I = 1, 1000
  NUM = FOO(B(i), C(I))
  X(I) = BAR(A(I), NUM)
! Assume FOO and BAR have no other effect
ENDDO
```

See examples of the auto-parallelization and auto-vectorization directives in the following topics.

Auto-Parallelization Options Quick Reference

These options are supported on IA-32, Intel® 64, and IA-64 architectures.

Linux* and Mac OS* X	Windows*	Description
-parallel	/Qparallel	Enables the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel. IA-64 architecture only: • Implies -opt-mem-bandwidth1 (Linux) or /Qopt-mem-bandwidth1 (Windows). Depending on the program and level of parallelization desired, you might need to set the KMP_STACKSIZE environment variable to an appropriately large size.

Linux* and Mac OS* X	Windows*	Description
`-par-threshold[n]`	`/Qpar-threshold[:n]`	Sets a threshold for the auto of loops based on the probability of profitable execution of the loop in parallel; valid values of *n* can be 0 to 100.
`-par-schedule-keyword`	`/Qpar-schedule-keyword`	Specifies the scheduling algorithm or a tuning method for loop iterations. It specifies how iterations are to be divided among the threads of the team.
`-par-report`	`/Qpar-report`	Controls the diagnostic levels in the auto-parallelizer optimizer.

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

Auto-parallelization: Enabling, Options, Directives, and Environment Variables

To enable the auto-parallelizer, use the `-parallel` (Linux* and Mac OS* X) or `/Qparallel` (Windows*) option. This option detects parallel loops capable of being executed safely in parallel and automatically generates multi-threaded code for these loops.

NOTE. You might need to set the `KMP_STACKSIZE` environment variable to an appropriately large size to enable parallelization with this option.

An example of the command using auto-parallelization is as follows:

Operating System	Description
Linux and Mac OS X	`ifort -c -parallel myprog.f`
Windows	`ifort -c /Qparallel myprog.f`

Auto-parallelization uses two specific directives, `!DEC$ PARALLEL` and `!DEC$ NO PARALLEL`.

Auto-parallelization Directives Format and Syntax

The format of an auto-parallelization compiler directive is:

Syntax

```
<prefix> <directive>
```

where the brackets above mean:

- <xxx>: the prefix and directive are required
  - For fixed form source input, the prefix is !DEC$ or CDEC$
  - For free form source input, the prefix is !DEC$ only

The prefix is followed by the directive name; for example:

Syntax

```
!DEC$ PARALLEL
```

Since auto-parallelization directives begin with an exclamation point, the directives take the form of comments if you omit the -parallel (Linux) or /Qparallel (Windows) option.

The !DEC$ PARALLEL directive instructs the compiler to ignore dependencies that it assumes may exist and which would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored.

The !DEC$ NOPARALLEL directive disables auto-parallelization for the following loop:

Example

```
program main
parameter (n=100
integer x(n),a(n)

!DEC$ NOPARALLEL
do i=1,n
  x(i) = i
enddo
```

Example

```
!DEC$ PARALLEL
do i=1,n
  a( x(i) ) = i
enddo
end
```

Auto-parallelization Environment Variables

Auto-parallelization uses the following OpenMP* environment variables.

- `OMP_NUM_THREADS`
- `OMP_SCHEDULE`
- `KMP_STACKSIZE`

See OpenMP* Environment Variables for more information about the default settings and how to use these variables.

Programming with Auto-parallelization

The auto-parallelization feature implements some concepts of OpenMP*, such as the worksharing construct (with the PARALLEL DO directive) . See Programming with OpenMP for worksharing construct. This section provides details on auto-parallelization.

Guidelines for Effective Auto-parallelization Usage

A loop can be parallelized if it meets the following criteria:

- The loop is countable at compile time: this means that an expression representing how many times the loop will execute (also called "the loop trip count") can be generated just before entering the loop.
- There are no `FLOW` (`READ` after `WRITE`), `OUTPUT` (`WRITE` after `WRITE`) or `ANTI` (`WRITE` after `READ`) loop-carried data dependencies. A loop-carried data dependency occurs when the same memory location is referenced in different iterations of the loop. At the compiler's discretion, a loop may be parallelized if any assumed inhibiting loop-carried dependencies can be resolved by run-time dependency testing.

The compiler may generate a run-time test for the profitability of executing in parallel for loop with loop parameters that are not compile-time constants.

Coding Guidelines

Enhance the power and effectiveness of the auto-parallelizer by following these coding guidelines:

- Expose the trip count of loops whenever possible; specifically use constants where the trip count is known and save loop parameters in local variables.
- Avoid placing structures inside loop bodies that the compiler may assume to carry dependent data, for example, procedure calls, ambiguous indirect references or global references.
- Insert the `!DEC$ PARALLEL` directive to disambiguate assumed data dependencies.
- Insert the `!DEC$ NOPARALLEL` directive before loops known to have insufficient work to justify the overhead of sharing among threads.

Auto-parallelization Data Flow

For auto-parallelization processing, the compiler performs the following steps:

1. Data flow analysis: Computing the flow of data through the program.
2. Loop classification: Determining loop candidates for parallelization based on correctness and efficiency, as shown by threshold analysis.
3. Dependency analysis: Computing the dependency analysis for references in each loop nest.
4. High-level parallelization: Analyzing dependency graph to determine loops which can execute in parallel, and computing run-time dependency.
5. Data partitioning: Examining data reference and partition based on the following types of access: `SHARED`, `PRIVATE`, and `FIRSTPRIVATE`.
6. Multithreaded code generation: Modifying loop parameters, generating entry/exit per threaded task, and generating calls to parallel run-time routines for thread creation and synchronization.

Programming for Multithread Platform Consistency

For applications where most of the computation is carried out in simple loops, Intel compilers may be able to generate a multithreaded version automatically. This information applies to applications built for deployment on symmetric multiprocessors (`SMP`), systems with Hyper-Threading Technology (HT Technology) enabled, and dual core processor systems.

The compiler can analyze dataflow in loops to determine which loops can be safely and efficiently executed in parallel. Automatic parallelization can sometimes result in shorter execution times. Compiler enabled auto-parallelization can help reduce the time spent performing several common tasks:

- searching for loops that are good candidates for parallel execution
- performing dataflow analysis to verify correct parallel execution
- adding parallel compiler directives manually

Parallelization is subject to certain conditions, which are described in the next section. If `-openmp` and `-parallel` (Linux* and Mac OS* X) or `/Qopenmp` and `/Qparallel` (Windows*) are both specified on the same command line, the compiler will only attempt to parallelize those functions that do not contain OpenMP* directives.

The following program contains a loop with a high iteration count:

Example

```
subroutine no_dep
  parameter (n=100000000)
  real a, c(n)
  do i = 1, n
    a = 2 * i - 1
    c(i) = sqrt(a)
  enddo
  print*, n, c(1), c(n)
end subroutine no_dep
```

Dataflow analysis confirms that the loop does not contain data dependencies. The compiler will generate code that divides the iterations as evenly as possible among the threads at runtime. The number of threads defaults to the number of processors but can be set independently using the `OMP_NUM_THREADS` environment variable. The increase in parallel speed for a given loop depends on the amount of work, the load balance among threads, the overhead of thread creation and synchronization, etc., but generally will be less than the number of threads. For a whole program, speed increases depend on the ratio of parallel to serial computation.

For builds with separate compiling and linking steps, be sure to link the OpenMP* runtime library when using automatic parallelization. The easiest way to do this is to use the Intel® compiler driver for linking.

Parallelizing Loops

Three requirements must be met for the compiler to parallelize a loop.

1. The number of iterations must be known before entry into a loop so that the work can be divided in advance. A while-loop, for example, usually cannot be made parallel.
2. There can be no jumps into or out of the loop.
3. The loop iterations must be independent.

In other words, correct results must not logically depend on the order in which the iterations are executed. There may, however, be slight variations in the accumulated rounding error, as, for example, when the same quantities are added in a different order. In some cases, such as summing an array or other uses of temporary scalars, the compiler may be able to remove an apparent dependency by a simple transformation.

Potential aliasing of pointers or array references is another common impediment to safe parallelization. Two pointers are aliased if both point to the same memory location. The compiler may not be able to determine whether two pointers or array references point to the same memory location. For example, if they depend on function arguments, run-time data, or the results of complex calculations. If the compiler cannot prove that pointers or array references are safe and that iterations are independent, the compiler will not parallelize the loop, except in limited cases when it is deemed worthwhile to generate alternative code paths to test explicitly for aliasing at run-time. If you know parallelizing a particular loop is safe and that potential aliases can be ignored, you can instruct the compiler to parallelize the loop using the `!DIR$ PARALLEL` directive.

The compiler can only effectively analyze loops with a relatively simple structure. For example, the compiler cannot determine the thread safety of a loop containing external function calls because it does not know whether the function call might have side effects that introduce dependences. Fortran90 programmers can use the `PURE` attribute to assert that subroutines and functions contain no side effects. You can invoke interprocedural optimization with the `-ipo` (Linux* OS and Mac OS X) or `/Qipo` (Windows) compiler option. Using this option gives the compiler the opportunity to analyze the called function for side effects.

When the compiler is unable to parallelize automatically loops you know to be parallel use OpenMP*. OpenMP* is the preferred solution because you, as the developer, understand the code better than the compiler and can express parallelism at a coarser granularity. On the other hand, automatic parallelization can be effective for nested loops, such as those in a matrix multiply. Moderately coarse-grained parallelism results from threading of the outer loop, allowing the inner loops to be optimized for fine-grained parallelism using vectorization or software pipelining.

If a loop can be parallelized, it's not always the case that it should be parallelized. The compiler uses a threshold parameter to decide whether to parallelize a loop. The `-par-threshold` (Linux* OS and Mac OS X) or `/Qpar-threshold` (Windows) compiler option adjusts this behavior. The threshold ranges from 0 to 100, where 0 instructs the compiler to always parallelize a safe loop and 100 instructs the compiler to only parallelize those loops for which a performance gain is highly probable. Use the `-par-report` (Linux* OS and Mac OS X) or `/Qpar-report`

(Windows) compiler option to determine which loops were parallelized. The compiler will also report which loops could not be parallelized indicate a probably reason why it could not be parallelized. See Auto-parallelization: Threshold Control and Diagnostics for more information on the using these compiler options.

Because the compiler does not know the value of *k*, the compiler assumes the iterations depend on each other, for example if k equals -1, even if the actual case is otherwise. You can override the compiler inserting `!DEC$ parallel`:

Example

```
subroutine add(k, a, b)
  integer :: k
  real :: a(10000), b(10000)
  !$DEC parallel
  do i = 1, 10000
    a(i) = a(i+k) + b(i)
  end do
end subroutine add
```

As the developer, it's your responsibility to not call this function with a value of *k* that is less than 10000; passing a value less than 10000 could to incorrect results.

Thread Pooling

Thread pools offer an effective approach to managing threads. A thread pool is a group of threads waiting for work assignments. In this approach, threads are created once during an initialization step and terminated during a finalization step. This simplifies the control logic for checking for failures in thread creation midway through the application and amortizes the cost of thread creation over the entire application. Once created, the threads in the thread pool wait for work to become available. Other threads in the application assign tasks to the thread pool. Typically, this is a single thread called the thread manager or dispatcher. After completing the task, each thread returns to the thread pool to await further work. Depending upon the work assignment and thread pooling policies employed, it is possible to add new threads to the thread pool if the amount of work grows. This approach has the following benefits:

- Possible runtime failures midway through application execution due to inability to create threads can be avoided with simple control logic.
- Thread management costs from thread creation are minimized. This in turn leads to better response times for processing workloads and allows for multithreading of finer-grained workloads.

A typical usage scenario for thread pools is in server applications, which often launch a thread for every new request. A better strategy is to queue service requests for processing by an existing thread pool. A thread from the pool grabs a service request from the queue, processes it, and returns to the queue to get more work.

Thread pools can also be used to perform overlapping asynchronous I/O. The I/O completion ports provided with the Win32* API allow a pool of threads to wait on an I/O completion port and process packets from overlapped I/O operations.

OpenMP* is strictly a fork/join threading model. In some OpenMP implementations, threads are created at the start of a parallel region and destroyed at the end of the parallel region. OpenMP applications typically have several parallel regions with intervening serial regions. Creating and destroying threads for each parallel region can result in significant system overhead, especially if a parallel region is inside a loop; therefore, the Intel OpenMP implementation uses thread pools. A pool of worker threads is created at the first parallel region. These threads exist for the duration of program execution. More threads may be added automatically if requested by the program. The threads are not destroyed until the last parallel region is executed.

Thread pools can be created on Windows and Linux using the thread creation API.

The function `CheckPoolQueue` executed by each thread in the pool is designed to enter a wait state until work is available on the queue. The thread manager can keep track of pending jobs in the queue and dynamically increase the number of threads in the pool based on the demand.

Using Parallelism: Automatic Vectorization

28

Automatic Vectorization Overview

The automatic vectorizer (also called the auto-vectorizer) is a component of the Intel® compiler that automatically uses SIMD instructions in the MMX™, Intel® Streaming SIMD Extensions (Intel® SSE, SSE2, SSE3 and SSE4 Vectorizing Compiler and Media Accelerators) and Supplemental Streaming SIMD Extensions (SSSE3) instruction sets. The vectorizer detects operations in the program that can be done in parallel, and then converts the sequential operations like one SIMD instruction that processes 2, 4, 8 or up to 16 elements in parallel, depending on the data type.

Automatic vectorization is supported on IA-32 and Intel® 64 architectures.

The section discusses the following topics, among others:

- High-level discussion of compiler options used to control or influence vectorization
- Vectorization Key Programming Guidelines
- Loop parallelization and vectorization
- Discussion and general guidelines on vectorization levels:
  - automatic vectorization
  - vectorization with user intervention
- Examples demonstrating typical vectorization issues and resolutions

The compiler supports a variety of directives that can help the compiler to generate effective vector instructions.

See Vectorization Support.

See *The Software Vectorization Handbook. Applying Multimedia Extensions for Maximum Performance*, A.J.C. Bik. Intel Press, June, 2004, for a detailed discussion of how to vectorize code using the Intel® compiler. Additionally, see the Related Publications topic in this document for other resources.

Automatic Vectorization Options Quick Reference

These options are supported on IA-32 and Intel® 64 architectures.

Linux* OS and Mac OS* X	Windows* OS	Description
-x	/Qx	Generates specialized code to run exclusively on processors with the extensions specified as the processor value. See Targeting IA-32 and Intel® 64 Architecture Processors Automatically for more information about using the option.
-ax	/Qax	Generates, in a single binary, code specialized to the extensions specified as the processor value and also generic IA-32 architecture code. The generic code is usually slower. See Targeting Multiple IA-32 and Intel® 64 Architecture Processors for Run-time Performance for more information about using the option.
-vec	/Qvec	Enables or disables vectorization and transformations enabled for vectorization. The default is that vectorization is enabled. Supported for IA-32 and Intel® 64 architectures only.
-vec-report	/Qvec-report	Controls the diagnostic messages from the vectorizer. See Vectorization Report.

Vectorization within the Intel® compiler depends upon ability of the compiler to disambiguate memory references. Certain options may enable the compiler to do better vectorization.

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

Programming Guidelines for Vectorization

The goal of vectorizing compilers is to exploit single-instruction multiple data (SIMD) processing automatically. Users can help however by supplying the compiler with additional information; for example, by using directives.

Guidelines

You will often need to make some changes to your loops. Follow these guidelines for loop bodies.

Use:

- straight-line code (a single basic block)
- vector data only; that is, arrays and invariant expressions on the right hand side of assignments. Array references can appear on the left hand side of assignments.
- only assignment statements

Avoid:

- function calls
- unvectorizable operations (other than mathematical)
- mixing vectorizable types in the same loop
- data-dependent loop exit conditions

To make your code vectorizable, you will often need to make some changes to your loops. However, you should make only the changes needed to enable vectorization and no others. In particular, you should avoid these common changes:

- loop unrolling; the compiler does it automatically.
- decomposing one loop with several statements in the body into several single-statement loops.

Restrictions

There are a number of restrictions that you should be consider. Vectorization depends on two major factors: hardware and style of source code.

Factor	Description
Hardware	The compiler is limited by restrictions imposed by the underlying hardware. In the case of Streaming SIMD Extensions, the vector memory operations are limited to stride-1 accesses with a preference to 16-byte-aligned memory references. This means that if the compiler abstractly recognizes a loop as vectorizable, it still might not vectorize it for a distinct target architecture.
Style of source code	The style in which you write source code can inhibit optimization. For example, a common problem with global pointers is that they often prevent the compiler from being able to prove that two memory references refer to distinct locations. Consequently, this prevents certain reordering transformations.

Many stylistic issues that prevent automatic vectorization by compilers are found in loop structures. The ambiguity arises from the complexity of the keywords, operators, data references, and memory operations within the loop bodies.

However, by understanding these limitations and by knowing how to interpret diagnostic messages, you can modify your program to overcome the known limitations and enable effective vectorization. The following sections summarize the capabilities and restrictions of the vectorizer with respect to loop structures.

Vectorization and Loops

Combine the `-parallel` (Linux* and Mac OS* X) or `/Qparallel` (Windows*) and `-x` (Linux) or `/Qx` (Windows) options to instructs the compiler to attempt both automatic loop parallelization and automatic loop vectorization in the same compilation.

In most cases, the compiler will consider outermost loops for parallelization and innermost loops for vectorization. If deemed profitable, however, the compiler may even apply loop parallelization and vectorization to the same loop.

See Guidelines for Effective Auto-parallelization Usage and Programming Guidelines for Vectorization.

In some rare cases successful loop parallelization (either automatically or by means of OpenMP* directives) may affect the messages reported by the compiler for a non-vectorizable loop in a non-intuitive way; for example, in the cases where `-vec-report2` (Linux and Mac OS X) or `/Qvec-report2` (Windows) option indicating loops were not successfully vectorized. (See Vectorization Report.)

Types of Vectorized Loops

For integer loops, the 64-bit MMX™ technology and 128-bit Intel® Streaming SIMD Extensions (Intel® SSE) provide SIMD instructions for most arithmetic and logical operators on 32-bit, 16-bit, and 8-bit integer data types.

Vectorization may proceed if the final precision of integer wrap-around arithmetic will be preserved. A 32-bit shift-right operator, for instance, is not vectorized in 16-bit mode if the final stored value is a 16-bit integer. Also, note that because the MMX™ and Intel® SSE instruction sets are not fully orthogonal (shifts on byte operands, for instance, are not supported), not all integer operations can actually be vectorized.

For loops that operate on 32-bit single-precision and 64-bit double-precision floating-point numbers, Intel® SSE provides SIMD instructions for the following arithmetic operators: addition (+), subtraction (-), multiplication (*), and division (/).

Additionally, the Streaming SIMD Extensions provide SIMD instructions for the binary `MIN` and `MAX` and unary `SQRT` operators. SIMD versions of several other mathematical operators (like the trigonometric functions `SIN`, `COS`, and `TAN`) are supported in software in a vector mathematical run-time library that is provided with the Intel® compiler of which the compiler takes advantage.

Statements in the Loop Body

The vectorizable operations are different for floating-point and integer data.

Integer Array Operations

The statements within the loop body may be arithmetic or logical operations (again, typically for arrays). Arithmetic operations are limited to such operations as addition, subtraction, `ABS`, `MIN`, and `MAX`. Logical operations include bitwise `AND`, `OR`, and `XOR` operators. You can mix data types only if the conversion can be done without a loss of precision. Some example operators where you can mix data types are multiplication, shift, or unary operators.

Other Operations

No statements other than the preceding floating-point and integer operations are valid. The loop body cannot contain any function calls other than the ones described above.

Data Dependency

Data dependency relations represent the required ordering constraints on the operations in serial loops. Because vectorization rearranges the order in which operations are executed, any auto-vectorizer must have at its disposal some form of data dependency analysis.

An example where data dependencies prohibit vectorization is shown below. In this example, the value of each element of an array is dependent on the value of its neighbor that was computed in the previous iteration.

Example 1: Data-dependent Loop

```
subroutine dep(data, n)
  real :: data(n)
  integer :: i
 do i = 1, n-1
    data(i) = data(i-1)*0.25 + data(i)*0.5 + data(i+1)*0.25
  end do
end subroutine dep
```

The loop in the above example is not vectorizable because the `WRITE` to the current element `DATA(I)` is dependent on the use of the preceding element `DATA(I-1)`, which has already been written to and changed in the previous iteration. To see this, look at the access patterns of the array for the first two iterations as shown below.

Example 2: Data-dependency Vectorization Patterns

```
I=1: READ DATA(0)
READ DATA(1)
READ DATA(2)
WRITE DATA(1)
I=2: READ DATA(1)
READ DATA(2)
READ DATA(3)
WRITE DATA(2)
```

In the normal sequential version of this loop, the value of `DATA(1)` read from during the second iteration was written to in the first iteration. For vectorization, it must be possible to do the iterations in parallel, without changing the semantics of the original loop.

Data dependency Analysis

Data dependency analysis involves finding the conditions under which two memory accesses may overlap. Given two references in a program, the conditions are defined by:

- whether the referenced variables may be aliases for the same (or overlapping) regions in memory
- for array references, the relationship between the subscripts

For IA-32 architecture, data dependency analyzer for array references is organized as a series of tests, which progressively increase in power as well as in time and space costs.

First, a number of simple tests are performed in a dimension-by-dimension manner, since independency in any dimension will exclude any dependency relationship. Multidimensional arrays references that may cross their declared dimension boundaries can be converted to their linearized form before the tests are applied.

Some of the simple tests that can be used are the fast greatest common divisor (GCD) test and the extended bounds test. The GCD test proves independency if the GCD of the coefficients of loop indices cannot evenly divide the constant term. The extended bounds test checks for potential overlap of the extreme values in subscript expressions.

If all simple tests fail to prove independency, the compiler will eventually resort to a powerful hierarchical dependency solver that uses Fourier-Motzkin elimination to solve the data dependency problem in all dimensions.

Loop Constructs

Loops can be formed with the usual `DO-END DO` and `DO WHILE`, or by using an `IF`/`GOTO` and a label. The loops must have a single entry and a single exit to be vectorized. The following examples illustrate loop constructs that can and cannot be vectorized.

Example: Vectorizable structure

```
subroutine vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
      if (a(i) .lt. 0.0) a(i) = 0.0
        i = i + 1
  enddo
end subroutine vec
```

The following example shows a loop that cannot be vectorized because of the inherent potential for an early exit from the loop.

Example: Non-vectorizable structure

```
subroutine no_vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
! The next statement allows early
!
exit from the loop and prevents
! vectorization of the loop.
    if (a(i) .lt. 0.0) go to 10
    i = i + 1
  enddo
  10 continue
end subroutine no_vecN
END
```

Loop Exit Conditions

Loop exit conditions determine the number of iterations a loop executes. For example, fixed indexes for loops determine the iterations. The loop iterations must be countable; in other words, the number of iterations must be expressed as one of the following:

- A constant
- A loop invariant term
- A linear function of outermost loop indices

In the case where a loops exit depends on computation, the loops are not countable. The examples below show loop constructs that are countable and non-countable.

Example: Countable Loop

```
subroutine cnt1 (a, b, c, n, lb)
  dimension a(n), b(n), c(n)
  integer n, lb, i, count
! Number of iterations is "n - lb + 1"
  count = n
  do while (count .ge. lb)
    a(i) = b(i) * c(i)
    count = count - 1
    i = i + 1
  enddo ! lb is not defined within loop
end
```

The following example demonstrates a different countable loop construct.

Example: Countable Loop

```
! Number of iterations is (n-m+2)/2
subroutine cnt2 (a, b, c, m, n)
  dimension a(n), b(n), c(n)
  integer i, l, m, n
  i = 1;
  do l = m,n,2
    a(i) = b(i) * c(i)
    i = i + 1
  enddo
end
```

The following examples demonstrates a loop construct that is non-countable due to dependency loop variant count value.

Example: Non-Countable Loop

```
! Number of iterations is dependent on a(i)
subroutine foo (a, b, c)
  dimension a(100),b(100),c(100)
  integer i
  i = 1
  do while (a(i) .gt. 0.0)
    a(i) = b(i) * c(i)
    i = i + 1
  enddo
end
```

Strip-mining and Cleanup

Strip-mining, also known as loop sectioning, is a loop transformation technique for enabling SIMD-encodings of loops, as well as a means of improving memory performance. By fragmenting a large loop into smaller segments or strips, this technique transforms the loop structure in two ways:

- It increases the temporal and spatial locality in the data cache if the data are reusable in different passes of an algorithm.
- It reduces the number of iterations of the loop by a factor of the length of each vector, or number of operations being performed per SIMD operation. In the case of Streaming SIMD Extensions, this vector or strip-length is reduced by 4 times: four floating-point data items per single Streaming SIMD Extensions single-precision floating-point SIMD operation are processed.

First introduced for vectorizers, this technique consists of the generation of code when each vector operation is done for a size less than or equal to the maximum vector length on a given vector machine.

The compiler automatically strip-mines your loop and generates a cleanup loop. For example, assume the compiler attempts to strip-mine the following loop:

Example1: Before Vectorization

```
i = 1
do while (i<=n)
  a(i) = b(i) + c(i) ! Original loop code
  i = i + 1
end do
```

The compiler might handle the strip mining and loop cleaning by restructuring the loop in the following manner:

Example 2: After Vectorization

```
!The vectorizer generates the following two loops
i = 1
do while (i < (n - mod(n,4)))
! Vector strip-mined loop.
  a(i:i+3) = b(i:i+3) + c(i:i+3)
  i = i + 4
end do
do while (i <= n)
  a(i) = b(i) + c(i)     !Scalar clean-up loop
  i = i + 1
end do
```

Loop Blocking

It is possible to treat loop blocking as strip-mining in two or more dimensions. Loop blocking is a useful technique for memory performance optimization. The main purpose of loop blocking is to eliminate as many cache misses as possible. This technique transforms the memory domain

into smaller chunks rather than sequentially traversing through the entire memory domain. Each chunk should be small enough to fit all the data for a given computation into the cache, thereby maximizing data reuse.

Consider the following example. The two-dimensional array *A* is referenced in the *j* (column) direction and then in the *i* (row) direction (column-major order); array *B* is referenced in the opposite manner (row-major order). Assume the memory layout is in column-major order; therefore, the access strides of array *A* and *B* for the code would be 1 and MAX, respectively. In example 2: `BS = block_size;` MAX must be evenly divisible by *BS*.

Consider the following loop example code:

Example: Original loop

```
REAL A(MAX,MAX), B(MAX,MAX)
DO I =1, MAX
  DO J = 1, MAX
    A(I,J) = A(I,J) + B(J,I)
  ENDDO
ENDDO
```

The arrays could be blocked into smaller chunks so that the total combined size of the two blocked chunks is smaller than the cache size, which can improve data reuse. One possible way of doing this is demonstrated below:

Example: Transformed Loop after blocking

```
REAL A(MAX,MAX), B(MAX,MAX)
DO I =1, MAX, BS
  DO J = 1, MAX, BS
   DO II = I, I+MAX, BS-1
    DO J = J, J+MAX, BS-1
     A(II,JJ) = A(II,JJ) + B(JJ,II
    ENDDO
   ENDDO
  ENDDO
ENDDO
```

Loop Interchange and Subscripts: Matrix Multiply

Loop interchange need unit-stride constructs to be vectorized. Matrix multiplication is commonly written as shown in the following example:

Example: Typical Matrix Multiplication

```
subroutine matmul_slow(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do i = 1, n
    do j = 1, n
      do k = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j);
      end do
    end do
  end do
end subroutine matmul_slow
```

The use of `B(K,J)` is not a stride-1 reference and therefore will not normally be vectorizable.

If the loops are interchanged, however, all the references will become stride-1 as shown in the following example.

Example: Matrix Multiplication with Stride-1

```
subroutine matmul_fast(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do j = 1, n
    do k = 1, n
      do i = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j)
      enddo
    enddo
  enddo
end subroutine matmul_fast
```

Interchanging is not always possible because of dependencies, which can lead to different results.

Absence of Loop-carried Memory Dependency with IVDEP Directive

For applications designed to run on IA-64 architectures, the `-ivdep-parallel` (Linux*) or `/Qivdep-parallel` (Windows*) option indicates there is no loop-carried memory dependency in the loop where an `ivdep` directive is specified. This technique is useful for some sparse matrix applications.

NOTE. Mac OS* X: This option is not supported.

For example, the following loop requires the parallel option in addition to the `ivdep` directive to ensure there is no loop-carried dependency for the store into `a()`.

Example

```
!DEC$ IVDEP
do j=1,n
  a(b(j)) = a(b(j))+1
enddo
```

Vectorization Examples

This section contains simple examples of some common issues in vector programming.

Argument Aliasing: A Vector Copy

The loop in the example of a vector copy operation does not vectorize because the compiler cannot prove that `DEST(A(I))` and `DEST(B(I))` are distinct.

Example: Unvectorizable Copy Due to Unproven Distinction

```
SUBROUTINE VEC_COPY(DEST,A,B,LEN)
DIMENSION DEST(*)
INTEGER A(*), B(*)
INTEGER LEN, I
  DO I=1,LEN
  DEST(A(I)) = DEST(B(I))
END DO
RETURN
END
```

Data Alignment

A 16-byte (Linux* and Mac OS* X) or 64-byte (Windows*) or greater data structure or array should be aligned so that the beginning of each structure or array element is aligned in a way that its base address is a multiple of 16 (Linux and Mac OS X) or 32 (Windows).

The figure (below) shows the effect of a data cache unit (DCU) split due to misaligned data. The code loads the misaligned data across a 16-byte boundary, which results in an additional memory access causing a six- to twelve-cycle stall. You can avoid the stalls if you know that the data is aligned and you specify to assume alignment.

Figure 20: Misaligned Data Crossing 16- Byte Boundary

After vectorization, the loop is executed as shown in figure below.

Figure 21: Vector and Scalar Clean-up iterations

Both the vector iterations `A(1:4) = B(1:4);` and `A(5:8) = B(5:8);` can be implemented with aligned moves if both the elements `A(1)` and `B(1)` are 16-byte aligned.

CAUTION. If you use the vectorizer with incorrect alignment options the compiler will generate code with unexpected behavior. Specifically, using aligned moves on unaligned data, will result in an illegal instruction exception.

Alignment Strategy

The compiler has at its disposal several alignment strategies in case the alignment of data structures is not known at compile-time. A simple example is shown below (several other strategies are supported as well). If in the loop shown below the alignment of A is unknown, the compiler will generate a prelude loop that iterates until the array reference, that occurs the most, hits an aligned address. This makes the alignment properties of A known, and the vector loop is optimized accordingly. In this case, the vectorizer applies dynamic loop peeling, a specific Intel® Fortran feature.

Examples of Data Alignment

Example: Original loop

```
SUBROUTINE SIMLOOP(A)
REAL A(100)    ! alignment of argument A is unknown
DO I = 1, 100
  A(I) = A(I) + 1.0
ENDDO
END SUBROUTINE
```

Example: Aligning Data

```
! The vectorizer applies dynamic loop peeling as follows:
SUBROUTINE SIMLOOP(A)
REAL A(100)
! let P be (A%16)where A is address of A(1)
IF (P .NE. 0) THEN
  P = (16 - P)/4   ! determine run-time peeling factor
  DO I = 1, P
    A(I) = A(I) + 1.0
  ENDDO
ENDIF
! Now this loop starts at a 16-byte boundary, and will be
! vectorized accordingly
DO I = P + 1, 100
  A(I) = A(I) + 1.0
ENDDO
END SUBROUTINE
```

Using Parallelism: Multi-Threaded Applications

29

Creating Multithread Applications Overview

Intel® Fortran provides support for creating multithread applications. You should consider using more than one thread if your application needs to manage multiple activities, such as simultaneous keyboard input and calculations. One thread can process keyboard input while a second thread performs data transformation calculations. A third thread can update the display screen based on data from the keyboard thread. At the same time, other threads can access disk files, or get data from a communications port.

When using a multiprocessor machine (sometimes called an "SMP machine") you can achieve a substantial speedup on numerically intensive problems by dividing the work among different threads; the operating system will assign the different threads to different processors (symmetric multiprocessing or parallel execution). Even if you have a single-processor machine, multiple-window applications might benefit from multithreading because threads can be associated with different windows; one thread can be calculating while another is waiting for input.

While you might gain execution speed by having a program executed in multiple threads, there is overhead involved in managing the threads. You need to evaluate the requirements of your project to determine whether you should run it with more than one thread.

If your multithreaded code calls functions from the run-time library or does input/output, you must also link your code to the multithreaded version of the run-time libraries instead of the regular single-threaded ones.

Basic Concepts of Multithreading

A *thread* is a path of execution through a program. It is an executable entity that belongs to one and only one process. Each process has at least one thread of execution, automatically created when the process is created. Your main program runs in the first thread. A Windows thread consists of a stack, the state of the CPU registers, a security context, and an entry in the execution list of the system scheduler. Each thread shares all of the process's resources.

A *process* consists of one or more threads and the code, data, and other resources of a program in memory. Typical program resources are open files, semaphores (a method of interthread communication), and dynamically allocated memory. A program executes when the system scheduler gives one of its threads execution control. The scheduler determines which threads should run and when they should run. Threads of lower priority might need to wait while higher priority threads complete their tasks. On multiprocessor machines, the scheduler can move individual threads to different processors to balance the CPU load.

Because threads require less system overhead and are easier to create than an entire process, they are useful for time- or resource-intensive operations that can be performed concurrently with other tasks. Threads can be used for operations such as background printing, monitoring a device for input, or backing up data while it is being edited.

When threads, processes, files, and communications devices are opened, the function that creates them returns a *handle*. Each handle has an associated Access Control List (ACL) that is used to check the security credentials of the process. Processes and threads can inherit a handle or give one away using functions described in this section. Objects and handles regulate access to system resources.

All threads in a process execute independently of one another. Unless you take special steps to make them communicate with each other, each thread operates while completely unaware of the existence of other threads in a process. Threads sharing common resources must coordinate their work by using semaphores or another method of interthread communication. For more information on interthread communication, see Sharing Resources.

Developing Multithread Applications

Writing a Multithread Program Overview

Multiple threads are best used for:

- Background tasks such as data calculations, database queries, and input gathering, which do not directly involve window management or user interface.
- Operations that are independent from one another that can benefit from concurrent processing.
- Asynchronous tasks such as polling on a serial port.

If your application contains tasks that require a private address space and private resources, you can protect them from the activities of other threads by creating multiple processes rather than multiple threads. See Working with Multiple Processes.

The sections that follow discuss the steps you need to consider in creating a multithread application:

- Modules for Multithread Programs

- Starting and Stopping Threads
- Thread Routine Format
- Sharing Resources
- Thread Local Storage (TLS)
- Synchronizing Threads
- Handling Errors in Multithread Programs
- Working with Multiple Processes
- Table of Multithread Routines

Modules for Multithread Programs

A module called `IFMT.MOD` is supplied with Intel® Visual Fortran.

It contains interface statements to the underlying Windows API routines as well as parameter and structure definitions used by the routines. You need to include a **`USE IFMT`** statement in the declarations section of every Fortran program unit (program, subroutine, function, or module) that uses multithread API routines.

The source code for the IFMT module (`IFMT.F90`) contains type definitions and external function declarations. You can use it as an added reference for the calling syntax, number, and type of arguments for a multithread procedure.

Other Windows APIs that support multithreading tasks (such as window management functions) are included in the `IFWIN.F90` module, available to your programs with the **`USE IFWIN`** statement.

For information about creating a Fortran Windows application, see Creating Windows Applications in Building Applications.

Starting and Stopping Threads

When you add threads to a process, you need to consider the costs to your process. Create only the number of threads that help your application respond and perform better. You can save time by multitasking, but remember that additional CPU time is needed to keep track of multiple threads. When you are deciding how many threads to create, you also need to consider what data can be process-specific, and what data is thread-specific. Sharing Resources discusses synchronizing access to variables and data.

One single call to the CreateThread function creates a thread, specifies security attributes and memory stack size, and names the routine for the thread to run. Windows allocates memory for the thread stack in the virtual address space of the application that contains the thread. Once a thread has finished processing, the CloseHandle routine frees the resources used by the thread.

Starting Threads

The `CreateThread` function creates a new thread. Its return value is an INTEGER(4) thread handle, used in communicating to the thread and when closing it. The syntax for this function is:

`CreateThread (`*`security`*`, `*`stack`*`, `*`thread_func`*`, `*`argument`*`, `*`flags`*`, `*`thread_id`*`)`

All arguments are INTEGER(4) variables except for *`thread_func`*, which names the routine for `CreateThread` to run. The arguments are as follows:

Argument	Description
`security`	This argument uses the `SECURITY_ATTRIBUTES` type, defined in `IFMT.F90`. If *`security`* is zero, the thread has the default security attributes of the parent process. For more information about setting security attributes for processes and threads, see the Platform SDK online reference.
`stack`	Defines the stack size of the new thread. All of an application's default stack space is allocated to the first thread of execution. As a result, you must specify how much memory to allocate for a separate stack for each additional thread your program needs. The `CreateThread` call allows you to specify the value for the stack size on each thread you create. A value of zero indicates the stack has the same size as the application's primary thread. The size of the stack is increased dynamically, if necessary, up to a limit of 1 MB.
`thread_func`	The starting address for the thread function.
`argument`	An optional argument for *`thread_func`*. Your program defines this parameter and how it is used.
`flags`	This argument lets you create a thread that will not begin processing until you signal it. The *`flags`* argument can take either of two

Argument	Description
	values: 0 or CREATE_SUSPENDED. If you specify 0, the thread is created and runs immediately after creation. If you specify CREATE_SUSPENDED, the thread is created, but does not run until you call the ResumeThread function.
thread_id	This argument is returned by CreateThread. It is a unique identifier for the thread, which you can use when calling other multithread routines. While the thread is running, no other thread has the same identifier. However, the operating system may use the identifier again for other threads once this one has completed. A thread can be referred to by its handle as well as its unique thread identifier. Synchronization functions such as WaitForSingleObject and WaitForMultipleObjects take the thread handle as an argument.

Stopping Threads

The ExitThread routine allows a thread to stop its own execution. The syntax is: CALL EXITTHREAD ([*Termination Status*])

Termination status may be queried by another thread. A termination status of 0 indicates normal termination. You can assign other termination status values and their meaning in your program.

When the called thread is no longer needed, the calling thread needs to close the handle for the thread. Use the CloseHandle routine to free memory used by the thread. A thread object is not deleted until the last thread handle is closed.

It is possible for more than one handle to be open to a thread: for example, if a program creates two threads, one of which waits for information from the other. In this case, two handles are open to the first thread: one from the thread requesting information, the other from the thread that created it. All handles are closed implicitly when the enclosing process terminates.

The TerminateThread routine allows one thread to terminate another, if the security attributes are set appropriately for both threads. DLLs attached to the thread are not notified that the thread is terminating, and its initial stack is not deallocated. Use Terminate Thread for emergencies only.

Other Thread Support Functions

Scheduling thread priorities is supported through the functions `GetThreadPriority` and `SetThreadPriority`. Use the priority class of a thread to differentiate between applications that are time critical and those that have normal or below normal scheduling requirements. If you need to manipulate priorities, be very careful not to give a thread too high a priority, or it can consume all of the available CPU time. A thread with a base priority level above 11 interferes with the normal operation of the operating system. Using `REALTIME_PRIORITY_CLASS` may cause disk caches to not flush, hang the mouse, and so on.

When communicating with other threads, a thread uses a *`pseudohandle`* to refer to itself. A pseudohandle is a special constant that is interpreted as the current thread handle. Pseudohandles are only valid for the calling thread; they cannot be inherited by other threads. The `GetCurrentThread` function returns a pseudohandle for the current thread. The calling thread can use this handle to specify itself whenever a thread handle is required. Pseudohandles are not inherited.

To get the thread's identifier, use the `GetCurrentThreadId` function. The identifier uniquely identifies the thread in the system until it terminates. You can use the identifier to specify the thread itself whenever an identifier is required.

Use `GetExitCodeThread` to find out if a thread is still active, or if it is not, to find its exit status. Call `GetLastError` for more detailed information on the exit status. If one routine depends on a task being performed by a different thread, use the wait functions described in Synchronizing Threads instead of `GetExitCodeThread`.

Thread Routine Format

A thread routine is a function that runs in a separate thread from the main program and takes a single argument. In the first interface below, the argument is the address of a integer(4) variable. It will be accessed as an INTEGER(4) in the body of `thread_proc` because of the `POINTER` attribute.

Example

```
INTERFACE
 integer(4) FUNCTION thread_proc(arg)
!DEC$ ATTRIBUTES STDCALL, ALIAS:"_thread_proc" :: thread_proc
 integer(4),POINTER :: arg
 END FUNCTION
END INTERFACE
```

In this second interface example, the argument is passed as an address of some undefined data in memory. You must create a pointer to a specific data type variable with the POINTER attribute and assign the `lpThreadParameter` argument to it in the body of the thread_proc routine. You can pass a pointer to an entire block of data with this method.

Example

```
INTERFACE
  integer(4) FUNCTION thread_proc(lpThreadParameter)
  !DEC$ ATTRIBUTES STDCALL, ALIAS:"_thread_proc" :: thread_proc
  integer(INT_PTR_KIND()) lpThreadParameter
 END FUNCTION
END INTERFACE
```

Example 1

```
Program TESTPROC0
   use ifcore
   use ifmt
   INTERFACE
    integer(4) FUNCTION Thread_Proc0(arg)
     !DEC$ ATTRIBUTES STDCALL, ALIAS:"_thread_proc0" :: Thread_Proc0
     integer(4),POINTER :: arg
    END FUNCTION
   END INTERFACE
   integer(INT_PTR_KIND()) ThreadHandle
   integer(INT_PTR_KIND()), PARAMETER :: security = 0
   integer(INT_PTR_KIND()), PARAMETER :: stack_size = 0
   integer(INT_PTR_KIND()) :: thread_id
   integer(4) :: ivalue0 = 12345678
   ThreadHandle = CreateThread(security,stack_size,Thread_Proc0,loc(ivalue0), &
      CREATE_SUSPENDED, thread_id )
```

Example 1

```
   iretlog = SetThreadPriority(ThreadHandle, THREAD_PRIORITY_BELOW_NORMAL )
   iretint = ResumeThread(ThreadHandle)
   call sleepqq(100) ! let io complete
end

integer(4) function Thread_Proc0(arg)
   USE IFCORE
   USE IFMT
   !DEC$ ATTRIBUTES STDCALL, ALIAS:"_thread_proc0" :: Thread_Proc0
   integer(4), POINTER :: arg
   write(6,*) "The value of the Thread_Proc0 argument is ",arg
   Thread_Proc0 = 0
   call ExitThread(0)
end function
```

The resulting output will be similar to the following example:

```
The value of the Thread_Proc0 argument is 12345678
```

Example 2

```
Program TESTPROC1
   use ifcore
   use ifmt
   INTERFACE
     integer(4) FUNCTION Thread_Proc1(lpThreadParameter)
     !DEC$ ATTRIBUTES STDCALL,ALIAS:"_thread_proc1" :: Thread_Proc1
     integer(INT_PTR_KIND()) lpThreadParameter
     END FUNCTION
   END INTERFACE
   integer(INT_PTR_KIND()) ThreadHandle1
   integer(INT_PTR_KIND()), PARAMETER :: security = 0
   integer(INT_PTR_KIND()), PARAMETER :: stack_size = 0
   integer(INT_PTR_KIND()) :: thread_id
   integer(4) :: ivalue1(5) = (/1,2,3,4,5/)
   ThreadHandle1 = CreateThread(security,stack_size,Thread_Proc1,loc(ivalue1(1)), &
      CREATE_SUSPENDED, thread_id )
   iretlog = SetThreadPriority(ThreadHandle1, THREAD_PRIORITY_BELOW_NORMAL )
   iretint = ResumeThread(ThreadHandle1)
   call sleepqq(100) ! let IO complete
end
```

Example 2

```
integer(4) function Thread_Proc1(lpThreadParameter)
  USE IFCORE
  USE IFMT
  !DEC$ ATTRIBUTES STDCALL, ALIAS:"_thread_proc1" :: Thread_Proc1
  integer(INT_PTR_KIND()) lpThreadParameter
  integer(4) arg(5)
  POINTER(parg,arg)
  parg = lpThreadParameter
  write(6,*) "The value of the Thread_Proc1 argument is ",arg
  Thread_Proc1 = 0
  call ExitThread(0)
end function
```

The resulting output will be similar to the following example:

```
The value of the Thread_Proc1 argument is 1 2 3 4 5
```

Sharing Resources

Each thread has its own stack and its own copy of the CPU registers. Other resources, such as files, units, static data, and heap memory, are shared by all threads in the process. Threads using these common resources must coordinate their work. There are several ways to synchronize resources:

- Critical section - A block of code that accesses a non-shareable resource. Critical sections are typically used to restrict access to data or code that can only be used by one thread at a time within a process (for example, modification of shared data in a common block).
- MUTual EXclusion object (Mutex) - A mechanism that allows only one thread at a time to access a resource. Mutexes are typically used to restrict access to a system resource that can only be used by one thread at a time (for example, a printer), or when sharing might produce unpredictable results.
- Semaphore - A counter that regulates the number of threads that can use a resource. Semaphores are typically used to control access to a specified number of identical resources.
- Event - An event object announces that an event has happened to one or more threads.

The state of each of these objects is either signaled or not-signaled. A signaled state indicates a resource is available for a process or thread to use it. A not-signaled state indicates the resource is in use.

The routines described in the following sections manage the creation, initialization, and termination of resource sharing mechanisms. Some of them change the state to signaled from not-signaled. The routines `WaitForSingleObject` and `WaitForMultipleObjects` also change the signal status of an object. For information on these functions, see Synchronizing Threads.

This section also contains information about:

- Memory Use and Thread Stacks
- I/O Operations

Critical Sections

Before you can synchronize threads with a critical section, you must initialize it by calling `InitializeCriticalSection`. Call `EnterCriticalSection` when beginning to process the global variable, and `LeaveCriticalSection` when the application is finished with it. Both `EnterCriticalSection` and `LeaveCriticalSection` can be called several times within an application.

Mutexes

`CreateMutex` creates a mutex object. It returns an error if the mutex already exists (one by the same name was created by another process or thread). Call `GetLastError` after calling `CreateMutex` to look for the error status `ERROR_ALREADY_EXISTS`. You can also use the `OpenMutex` function to determine whether or not a named mutex object exists. When called, `OpenMutex` returns the object's handle if it exists, or null if a mutex with the specified name is not found. Using `OpenMutex` does not change a mutex object to a signaled state; this is accomplished by one of the wait routines described in Synchronizing Threads.

`ReleaseMutex` changes a mutex from the not-signaled state to the signaled state. This function only has an effect if the thread calling it also owns the mutex. When the mutex is in a signaled state, any thread waiting for it can acquire it and begin executing.

Semaphores

Functions for handling semaphores are nearly identical to functions that manage mutexes. `CreateSemaphore` creates a semaphore, specifying an initial as well as a maximum count for the number of threads that can access the resource. `OpenSemaphore`, like `OpenMutex`, returns the handle of the named semaphore object, if it exists. The handle can then be used in any function that requires it (such as one of the wait functions described in Synchronizing Threads). Calling `OpenSemaphore` does not reduce a resource's available count; this is accomplished by the function waiting for the resource.

Use `ReleaseSemaphore` to increase the available count for a resource by a specified amount. You can call this function when the thread is finished with the resource. Another possible use is to call `CreateSemaphore`, specifying an initial count of zero to protect the resource from access during an initialization process. When the application has finished its initialization, call `ReleaseSemaphore` to increase the resource's count to its maximum.

Events

Event objects can trigger execution of other threads. You can use events if one thread provides data to several other threads. An event object is created by the `CreateEvent` function. The creating thread specifies the initial state of the object and whether it is a manual-reset or auto-reset event. A manual-reset event is one whose state remains signaled until it is explicitly reset by a call to `ResetEvent`. An auto-reset event is automatically reset by the system when a single waiting thread is released.

Use either `SetEvent` or `PulseEvent` to set an event object's state to signaled. `OpenEvent` returns a handle to the event, which can be used in other function calls. `ReleaseEvent` releases ownership of the event.

Memory Use and Thread Stacks

Because each thread has its own stack, you can avoid potential collisions over data items by using as little static data as possible. Design your program to use automatic stack variables for all data that can be private to a thread. All the variables declared in a multithread routine are by default static and shared among the threads. If you do not want one thread to overwrite a variable used by another, you can do one of the following:

- Declare the variable as `AUTOMATIC`.
- Create a vector of variable values, one for each thread, so that the variable values for different threads are in different storage locations. (You can use the single integer parameter passed by `CreateThread` as an index to identify the thread.)
- Use Thread Local Storage (TLS).

Variables declared as automatic are placed on the stack, which is part of the thread context saved with the thread. Automatic variables within procedures are discarded when the procedure completes execution.

I/O Operations

Although files and units are shared between threads, you may not need to coordinate the use of these shared resources by threads. Fortran treats each input/output statement as an atomic operation. If two separate threads try to write to the same unit and one thread's output operation has started, the operation will complete before the other thread's output operation can begin.

The operating system does not impose an ordering on threads' access to units or files. For example, the non-determinate nature of multithread applications can cause records in a sequential file to be written in a different order on each execution of the application as each

thread writes to the file. Direct access files might be a better choice than sequential files in such a case. If you cannot use direct access files, use mutexes to impose an ordering constraint on input or output of sequential files.

Certain restrictions apply to blocking functions for input procedures in QuickWin programs. For details on these restrictions, see Using QuickWin in Building Applications.

Thread Local Storage

Thread Local Storage (TLS) calls allow you to store per-thread data. TLS is the method by which each thread in a multithreaded process can allocate locations in which to store thread-specific data.

Dynamically bound (run-time) thread-specific data is supported by routines such as `TlsAlloc` (allocates an index to store data), `TlsGetValue` (retrieves values from an index), `TlsSetValue` (stores values into an index), and `TlsFree` (frees the dynamic storage). Threads allocate dynamic storage and use `TlsSetValue` to associate the index with a pointer to that storage. When a thread needs to access the storage, it calls `TlsGetValue`, specifying the index.

When all threads have finished using the index, `TlsFree` frees the dynamic storage.

Synchronizing Threads

The routines `WaitForSingleObject` and `WaitForMultipleObjects` enable threads to wait for a variety of different occurrences, such as thread completion or signals from other threads. They enable threads and processes to wait efficiently, consuming no CPU resources, either indefinitely or until a specified timeout interval has elapsed.

WaitForSingleObject takes an object handle as the first parameter and does not return until the object referenced by the handle either reaches a signaled state or until a specified timeout value elapses. The syntax is:

`WaitResult` `= WaitForSingleObject (`*`ObjectHandle`*`, [ `*`Timeout`*` ] )`

If you are using a timeout, specify the value in milliseconds as the second parameter. The value `WAIT_INFINITE` represents an infinite timeout, in which case the function waits until *`ObjectHandle`* completes.

`WaitForMultipleObjects` is similar, except that its second parameter is an array of Windows object handles. Specify the number of handles to wait for in the first parameter. This can be less than the total number of threads created, and its maximum is 64. The function can either wait until all events have completed, or resume as soon as any one of the objects completes.

Deadlocks occur when a thread waits for objects that never become available. Use the timeout parameter when there is a chance that the thread you are waiting for may never terminate.

Suspending and Resuming Threads

You can use `SuspendThread` to stop a thread from executing. `SuspendThread` is not particularly useful for synchronization because it does not control the point in the code at which the thread's execution is suspended. However, you could suspend a thread if you need to confirm the user input that would terminate the work of the thread. If confirmed, the thread is terminated; otherwise, it resumes.

If a thread is created in a suspended state, it does not begin to run until `ResumeThread` is called with a handle to the suspended thread. This can be useful for initializing the thread's state before it begins to run. Suspending a thread at creation can be useful for one-time synchronization, because `ResumeThread` ensures that the suspended thread will resume running at the starting point of its code.

Handling Errors in Multithread Programs

Use the `GetLastError` function to obtain error information if any of the multithreading routines returns an error code. Remember that it returns the error code of the last error, not necessarily the error status of the last call.

Error codes are 32-bit values. Bit 29 is reserved for application-defined error codes. You can set this bit and use `SetLastError` if you are creating your own dynamic-link library, to emulate Windows API behavior. Windows functions only call `SetLastError` when they fail, not when they succeed.

The last error code value is kept in Thread Local Storage, so that multiple threads do not overwrite each other's values.

Table of Multithread Routines

The following table lists routines available for multithread programs. For more information on these routines, see the Microsoft Developer Network (MSDN) or platform SDK documentation.

Routine	Description
`CloseHandle`	Closes an open object handle.
`CreateEvent`	Creates a named or unnamed event object.
`CreateMutex`	Creates a named or unnamed mutex object.
`CreateProcess`	Creates a new process and its primary thread.
`CreateSemaphore`	Creates a named or unnamed semaphore object.

Routine	Description
CreateThread	Creates a thread to execute within the address space of the calling process.
DeleteCriticalSection	Releases all resources used by an unowned critical section object.
DuplicateHandle	Duplicates an object handle.
EnterCriticalSection	Waits for ownership of the specified critical section object.
ExitProcess	Ends a process and all its threads.
ExitThread	Ends a thread.
GetCurrentProcess	Returns a pseudohandle for the current process.
GetCurrentProcessId	Returns the process identifier of the calling process.
GetCurrentThread	Returns a pseudohandle for the current thread.
GetCurrentThreadId	Returns the thread identifier of the calling thread.
GetExitCodeProcess	Retrieves the termination status of the specified process.
GetExitCodeThread	Retrieves the termination status of the specified thread.
GetLastError	Returns the calling thread's last-error code value.
GetPriorityClass	Returns the priority class for the specified process.
GetThreadPriority	Returns the priority value for the specified thread.

Routine	Description
InitializeCriticalSection	Initializes a critical section object.
LeaveCriticalSection	Releases ownership of the specified critical section object.
OpenEvent	Returns a handle of an existing named event object.
OpenMutex	Returns a handle of an existing named mutex object.
OpenProcess	Returns a handle of an existing process object.
OpenSemaphore	Returns a handle of an existing named semaphore object.
PulseEvent	As a single operation, sets (to signaled) and then resets the state of the specified event object after releasing the appropriate number of waiting threads.
ReleaseMutex	Releases ownership of the specified mutex object.
ReleaseSemaphore	Increases the count of the specified semaphore object by a specified amount.
ResetEvent	Sets the state of the specified event object to nonsignaled.
ResumeThread	Decrements a thread's suspend count. When the suspend count is zero, execution of the thread resumes.
SetEvent	Sets the state of the specified event object to signaled.
SetLastError	Sets the last-error code for the calling thread.
SetPriorityClass	Sets the priority class for the specified process.

Routine	Description
SetThreadPriority	Sets the priority value for the specified thread.
SuspendThread	Suspends the specified thread.
TerminateProcess	Terminates the specified process and all of its threads.
TerminateThread	Terminates a thread.
TlsAlloc	Allocates a thread local storage (TLS) index.
TlsFree	Releases a thread local storage (TLS) index, making it available for reuse.
TlsGetValue	Retrieves the value in the calling thread's thread local storage (TLS) slot for a specified TLS index.
TlsSetValue	Stores a value in the calling thread's thread local storage (TLS) slot for a specified TLS index.
WaitForMultipleObjects	Returns either any one or all of the specified objects are in the signaled state or when the time-out interval elapses.
WaitForSingleObject	Returns when the specified object is in the signaled state or the time-out interval elapses.

If a function mentioned in this section is not listed in the preceding table, it is only available through the **USE IFWIN** statement.

Working with Multiple Processes

The multithread libraries provide a number of routines for working with multiple processes. An application can use multiple processes for functions that require a private address space and private resources, to protect them from the activities of other threads. It is usually more efficient to implement multitasking by creating several threads in one process, rather than by creating multiple processes, for these reasons:

- The system can create and execute threads more quickly than it can create processes, since the code for threads has already been mapped into the address space of the process, while the code for a new process must be loaded.
- All threads of a process share the same address space and can access the process's global variables, which can simplify communications between threads.
- All threads of a process can use open handles to resources such as files and pipes.

If you want to create an independent process that runs concurrently with the current one, use `CreateProcess`. `CreateProcess` returns a process identifier that is valid until the process terminates. `ExitProcess` stops the process and notifies all DLLs the process is terminating.

Different processes can share mutexes, events, and semaphores (but not critical sections). Processes can also optionally inherit handles from the process that created them (see online help for `CreateProcess`).

You can obtain information about the current process by calling `GetCurrentProcess` (returns a pseudohandle to its own process), and `GetCurrentProcessId` (returns the process identifier). The value returned by these functions can be used in calls to communicate with other processes. `GetExitCodeProcess` returns the exit code of a process, or an indication that it is still running.

The `OpenProcess` function opens a handle to a process specified by its process identifier. `OpenProcess` allows you to specify the handle's access rights and inheritability.

A process terminates whenever one of the following occurs:

- Any thread of the process calls `ExitProcess`
- The primary thread of the process returns
- The last thread of the process terminates
- `TerminateProcess` is called with a handle to the process

`ExitProcess` is the preferred way to terminate a process because it notifies all attached DLLs of the termination, and ensures that all threads of the process terminate. DLLs are not notified after a call to `TerminateProcess`.

Using Interprocedural Optimization (IPO)

30

Interprocedural Optimization (IPO) Overview

Interprocedural Optimization (IPO) allows the compiler to analyze your code to determine where you can benefit from specific optimizations. In many cases, the optimizations that can be applied are related to the specific architectures.

The compiler might apply the following optimizations for the listed architectures:

Architecture	Optimization
IA-32, Intel® 64, and IA-64 architectures	• inlining • constant propagation • mod/ref analysis • alias analysis • forward substitution • routine key-attribute propagation • address-taken analysis • partial dead call elimination • symbol table data promotion • common block variable coalescing • dead function elimination • unreferenced variable removal • whole program analysis • array dimension padding • common block splitting • stack frame alignment • structure splitting and field reordering • formal parameter alignment analysis • indirect call conversion • specialization

Architecture	Optimization
IA-32 and Intel® 64 architectures	• Passing arguments in registers to optimize calls and register usage
IA-64 architecture only	• removing redundant EXTEND instructions • short data section allocation • prefetch analysis

IPO is an automatic, multi-step process: compilation and linking; however, IPO supports two compilation models: single-file compilation and multi-file compilation.

Single-file compilation, which uses the `-ip` (Linux* OS and Mac OS* X) or `/Qip` (Windows* OS) option, results in one, real object file for each source file being compiled. During single-file compilation the compiler performs inline function expansion for calls to procedures defined within the current source file.

The compiler performs some single-file interprocedural optimization at the default optimization level: `-O2` (Linux* and Mac OS* X) or `/O2` (Windows*); additionally some the compiler performs some inlining for the `-O1` (Linux* and Mac OS* X) or `/O1` (Windows*) optimization level, like inlining functions marked with inlining directives.

Multi-file compilation, which uses the `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows) option, results in one or more mock object files rather than normal object files. (See the *Compilation* section below for information about mock object files.) Additionally, the compiler collects information from the individual source files that make up the program. Using this information, the compiler performs optimizations across functions and procedures in different source files. Inlining is the most powerful optimization supported by IPO. See Inline Function Expansion.

NOTE. Inlining and other optimizations are improved by profile information. For a description of how to use IPO with profile information for further optimization, see Profile an Application.

Mac OS* X: Intel®-based systems running Mac OS X do not support a multiple object compilation model.

Compilation

As each source file is compiled with IPO, the compiler stores an intermediate representation (IR) of the source code in a mock object file, which includes summary information used for optimization. The mock object files contain the IR, instead of the normal object code. Mock object files can be ten times larger, and in some cases more, than the size of normal object files.

During the IPO compilation phase only the mock object files are visible. The Intel compiler does not expose the real object files during IPO unless you also specify the `-ipo-c` (Linux and Mac OS X) or `/Qipo-c` (Windows) option.

Linkage

When you link with the `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows) option the compiler is invoked a final time. The compiler performs IPO across all object files that have an IR equivalent. The mock objects must be linked with the Intel compiler or by using the Intel linking tools. The compiler calls the linkers indirectly by using aliases (or wrappers) for the native linkers, so you must modify make files to account for the different linking tool names. For information on using the linking tools, see Using IPO; see the Linking Tools and Options topic for detailed information.

CAUTION. Linking the mock object files with ld (Linux and Mac OS X) or link.exe (Windows) will cause linkage errors. You must use the Intel linking tools to link mock object files.

During the compilation process, the compiler first analyzes the summary information and then produces mock object files for source files of the application.

Whole program analysis

The compiler supports a large number of IPO optimizations that either can be applied or have the effectiveness greatly increased when the whole program condition is satisfied.

Whole program analysis, when it can be done, enables many interprocedural optimizations. During the analysis process, the compiler reads all Intermediate Representation (IR) in the mock file, object files, and library files to determine if all references are resolved and whether or not a given symbol is defined in a mock object file. Symbols that are included in the IR in a mock object file for both data and functions are candidates for manipulation based on the results of whole program analysis.

There are two types of whole program analysis: object reader method and table method. Most optimizations can be applied if either type of whole program analysis determine that the whole program conditions exists; however, some optimizations require the results of the object reader method, and some optimizations require the results of table method.

NOTE. The IPO report provides details about whether whole program analysis was satisfied and indicate the method used during IPO compilation.

In the first type of whole program analysis, the object reader method, the object reader emulates the behavior of the native linker and attempts to resolve the symbols in the application. If all symbols are resolved correctly, the whole program condition is satisfied. This type of whole program analysis is more likely to detect the whole program condition.

Often the object files and libraries accessed by the compiler do not represent the whole program; there are many dependencies to well-known libraries. IPO linking, whole program analysis, determines whether or not the whole program can be detected using the available compiler resources.

The second type of whole program analysis, the table method, is where the compiler analyzes the mock object files and generates a call-graph.

The compiler contains detailed tables about all of the functions for all important language-specific libraries, like the Fortran runtime libraries. In this second method, the compiler constructs a call-graph for the application. The compiler then compares the function table and application call-graph. For each unresolved function in the call-graph, the compiler attempts to resolve the calls. If the compiler can resolve the functions call, the whole program condition exists.

Interprocedural Optimization (IPO) Quick Reference

IPO is a two step process: compile and link. See Using IPO.

Linux* and Mac OS* X	Windows*	Description
`-ipo` or `-ipo`*N*	`/Qipo` or `/Qipo`*N*	Enables interprocedural optimization for multi-file compilations. Normally, multi-file compilations result in a single object file only. Passing an integer value for *N* allows you to specify number of true

Linux* and Mac OS* X	Windows*	Description
		object files to generate; the default value is 0, which means the compiler determines the appropriate number of object files to generate. (See IPO for Large Programs.)
`-ipo-separate`	`/Qipo-separate`	Instructs the compiler to generate a separate, real object file for each mock object file. Using this option overrides any integer value passed for `ipo`*N*. (See IPO for Large Programs for specifics.)
`-ip`	`/Qip`	Enables interprocedural optimizations for single file compilations. Instructs the compiler to generate a separate, real object file for each source file.

Additionally, the compiler supports options that provide support for compiler-directed or developer-directed inline function expansion.

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

Using IPO

This topic discusses how to use IPO from a command line. For specific information on using IPO from within an Integrated Development Environment (IDE), refer to the appropriate section in Building Applications.

Compiling and Linking Using IPO

The steps to enable IPO for compilations targeted for IA-32, Intel® 64, and IA-64 architectures are the same: compile and link.

First, compile your source files with `-ipo` (Linux* and Mac OS* X) or `/Qipo` (Windows*) as demonstrated below:

Operating System	Example Command
Linux and Mac OS X	`ifort -ipo -c a.f90 b.f90 c.f90`
Windows*	`ifort /Qipo /c a.f90 b.f90 c.f90`

The output of the above example command differs according to operating system:

- Linux and Mac OS X: The commands produce `a.o`, `b.o`, and `c.o` object files.
- Windows: The commands produce `a.obj`, `b.obj`, and `c.obj` object files.

Use `-c` (Linux and Mac OS X) or `/c` (Windows) to stop compilation after generating `.o` or `.obj` files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files. (See the section below on capturing the intermediate IPO output.)

Second, link the resulting files. The following example command will produce an executable named `app`:

Operating System	Example Command
Linux and Mac OS X	`ifort -o app a.o b.o c.o`
Windows	`ifort /exe:app a.obj b.obj c.obj`

The command invoke the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the `xild` (Linux and Mac OS X) or `xilink` (Windows) tool, with the appropriate linking options.

Combining the Steps

The separate compile and link commands demonstrated above can be combined into a single command, as shown in the following examples:

Operating System	Example Command
Linux and Mac OS X	`ifort -ipo -o app a.f90 b.f90 c.f90`
Windows	`ifort /Qipo /exe:app a.f90 b.f90 c.f90`

The `ifort` command, shown in the examples above, calls `GCC ld` (Linux and Mac OS X) or Microsoft* `link.exe` (Windows only) to link the specified object files and produce the executable application, which is specified by the `-o` (Linux and Mac OS X) or `/exe` (Windows) option.

Capturing Intermediate IPO Output

The `-ipo-c` (Linux and Mac OS X) or `/Qipo-c` (Windows*) and `-ipo-S` (Linux and Mac OS X) or `/Qipo-S` (Windows) options are useful for analyzing the effects of multi-file IPO, or when experimenting with multi-file IPO between modules that do not make up a complete program.

- Use the `-ipo-c` option to optimize across files and produce an object file. The option performs optimizations as described for the `-ipo` option but stops prior to the final link stage, leaving an optimized object file. The default name for this file is `ipo_out.s` (Linux and Mac OS X) or `ipo_out.obj` (Windows).
- Use the `-ipo-S` option to optimize across files and produce an assembly file. The option performs optimizations as described for `-ipo`, but stops prior to the final link stage, leaving an optimized assembly file. The default name for this file is `ipo_out.s` (Linux) or `ipo_out.asm` (Windows).

For both options, you can use the `-o` (Linux and Mac OS X) or `/exe` (Windows) option to specify a different name.

These options generate multiple outputs if multi-object IPO is being used. The name of the first file is taken from the value of the `-o` (Linux and Mac OS X) or /exe (Windows) option.

The names of subsequent files are derived from the first file with an appended numeric value to the file name. For example, if the first object file is named `foo.o` (Linux and Mac OS X) or `foo.obj` (Windows), the second object file will be named `foo1.o` or `foo1.obj`.

You can use the object file generated with the `-ipo-c` (Linux and Mac OS X) or `/Qipo-c` (Windows) option, but you will not get the same benefits from the optimizations applied that would otherwise if the whole program analysis condition had been satisfied.

The object file created using the `-ipo-c` option is a real object file, in contrast to the mock file normally generated using IPO; however, the generated object file is significantly different than the mock object file. It does not contain the IR information needed to fully optimize the application using IPO.

The compiler generates a message indicating the name of each object or assembly file it generates. These files can be added to the real link step to build the final application.

IPO-Related Performance Issues

There are some general optimization guidelines for IPO that you should keep in mind:

- Large IPO compilations might trigger internal limits of other compiler optimization phases.
- Combining IPO and PGO can be a key technique for C++ applications. The `-O3`, `-ipo`, and `-prof-use` (Linux* and Mac OS* X) or `/O3`, `/Qipo`, `/Qprof-use` (Windows*) options can result in significant performance gains.
- IPO benefits C more than C++, since C++ compilations include intra-file inlining by default.
- Applications where the compiler does not have sufficient intermediate representation (IR) coverage to do whole program analysis might not perform as well as those where IR information is complete.

In addition to the general guidelines, there are some practices to avoid while using IPO. The following list summarizes the activities to avoid:

- Do not use the link phase of an IPO compilation using mock object files produced for your application by a different compiler. The Intel® Compiler cannot inspect mock object files generated by other compilers for optimization opportunities.
- Do not link mock files with the `-prof-use` (Linux* and Mac OS* X) or `/Qprof-use` (Windows*) option unless the mock files were also compiled with the `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) option.
- Update make files to call the appropriate Intel linkers when using IPO from scripts. For Linux and Mac OS X, replaces all instances of `ld` with `xild`; for Windows, replace all instances of `link` with `xilink`.
- Update make file to call the appropriate Intel archiver. Replace all instances of `ar` with `xiar`.

IPO for Large Programs

In most cases, IPO generates a single object file for the link-time compilation. This behavior is not optimal for very large programs, perhaps even making it impossible to use `-ipo` (Linux* and Mac OS* X) or `/Qipo` (Windows*) on the application.

The compiler provides two methods to avoid this problem. The first method is an automatic size-based heuristic, which causes the compiler to generate multiple object files for large link-time compilations. The second method is to manually instruct the compiler to perform multi-object IPO.

- Use the `-ipo`*N* (Linux and Mac OS X) or `/Qipo`*N* (Windows) option and pass an integer value in the place of *N*.

- Use the `-ipo-separate` (Linux and Mac OS X) or `/Qipo-separate` (Windows) option.

  The number of true object files generated by the link-time compilation is invisible to the user unless either the `-ipo-c` or `-ipo-S` (Linux and Mac OS X) or `/Qipo-c` or `/Qipo-S` (Windows) option is used.

Regardless of the method used, it is best to use the compiler defaults first and examine the results. If the defaults do not provide the expected results then experiment with generating more object files.

You can use the `-ipo-jobs` (Linux and Mac OS X) or `/Qipo-jobs` (Windows) option to control the number of commands, or jobs, executed during parallel builds.

Using -ipo*N* or /Qipo*N* to Create Multiple Object Files

If you specify `-ipo0` (Linux and Mac OS X) or `/Qipo0` (Windows), which is the same as not specifying a value, the compiler uses heuristics to determine whether to create one or more object files based on the expected size of the application. The compiler generates one object file for small applications, and two or more object files for large applications. If you specify any value greater than 0, the compiler generates that number of object files, unless the value you pass a value that exceeds the number of source files. In that case, the compiler creates one object file for each source file then stops generating object files.

The following example commands demonstrate how to use `-ipo2` (Linux and Mac OS X) or `/Qipo2` (Windows) to compile large programs.

Operating System	Example Command
Linux and Mac OS X	`ifort -ipo2 -c a.f90 b.f90`
Windows	`ifort /Qipo2 /c a.f90 b.f90`

Because the example command shown above, the compiler generates object files using an OS-dependent naming convention. On Linux and Mac OS X, the example command results in object files named `ipo_out.o`, `ipo_out1.o`, `ipo_out2.o`, and `ipo_out3.o`. On Windows, the file names follow the same convention; however, the file extensions will be `.obj`.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

Creating the Maximum Number of Object Files

Using `-ipo-separate` (Linux and Mac OS X) or `/Qipo-separate` (Windows) allows you to force the compiler to generate the maximum number of true object files that the compiler will support during multiple object compilation.

For example, if you passed example commands similar to the following:

Operating System	Example Command
Linux and Mac OS X	`ifort a.o b.o c.o -ipo-separate -ipo-c`
Windows	`ifort a.obj b.obj c.obj /Qipo-separate /Qipo-c`

The compiler will generate multiple object file, which use the same naming convention discussed above. The first object file contains global variables. The other object files contain code for the functions or routines used the source files.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

Considerations for Large Program Compilation

For many large programs, compiling with IPO can result in a single, large object file. Compiling to produce large objects can create problems for efficient compilation. During compilation, the compiler attempts to swap the memory usage during compiles; a large object file might result in poor swap usage, which could result in out-of-memory message or long compilation times. Using multiple, relatively small object files during compilation causes the system to use resources more efficiently.

Understanding Code Layout and Multi-Object IPO

One of the optimizations performed during an IPO compilation is code layout. The analysis performed by the compiler during multi-file IPO determines a layout order for all of the routines for which it has intermediate representation (IR) information. For a multi-object IPO compilation, the compiler must tell the linker about the desired order.

If you are generating an executable in the link step, the compiler does all of this automatically. However, if you are generating object files instead of an executable, the compiler generates a layout script, which contains the correct information needed to optimally link the executable when you are ready to create it.

This linking tool script must be taken into account if you use either `-ipo-c` or `-ipo-S` (Linux*) or `/Qipo-c` or `/Qipo-S` (Windows*). With these options, the IPO compilation and actual linking are done by different invocations of the compiler. When this occurs, the compiler issues a message indicating that it is generating an explicit linker script, `ipo_layout.script`.

The Windows linker (link.exe) automatically collates these sections lexigraphically in the desired order.

The compiler first puts each routine in a named text section that varies depending on the operating system:

Windows:

- The first routine is placed in `.text$00001`, the second is placed in `.text$00002`, and so on.

Linux:

- The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on. It then generates a linker script that tells the linker to first link contributions from `.text00001`, then `.text00002`.

When `ipo_layout.script` is generated, you should modify your link command if you want to use the script to optimize code layout:

Example

```
--script=ipo_layout.script
```

If your application already requires a custom linker script, you can place the necessary contents of `ipo_layout.script` in your script.

The layout-specific content of `ipo_layout.script` is at the beginning of the description of the `.text` section. For example, to describe the layout order for 12 routines:

Example output

```
.text     :
{
*(.text00001) *(.text00002) *(.text00003) *(.text00004) *(.text00005)
*(.text00006) *(.text00007) *(.text00008) *(.text00009) *(.text00010)
*(.text00011) *(.text00012)
...
```

For applications that already require a linker script, you can add this section of the `.text` section description to the customized linker script. If you add these lines to your linker script, it is desirable to add additional entries to account for future development. The addition is harmless, since the "r;*("¦)" syntax makes these contributions optional.

If you choose to not use the linker script your application will still build, but the layout order will be random. This may have an adverse affect on application performance, particularly for large applications.

Creating a Library from IPO Objects

Linux* and Mac OS* X

Libraries are often created using a library manager such as `lib`. Given a list of objects, the library manager will insert the objects into a named library to be used in subsequent link steps.

Example
`xiar cru user.a a.o b.o`

The above command creates a library named `user.a` containing the `a.o` and `b.o` objects.

If the objects have been created using `-ipo-c` then the archive will not only contain a valid object, but the archive will also contain intermediate representation (IR) for that object file. For example, the following example will produce `a.o` and `b.o` that may be archived to produce a library containing both object code and IR for each source file.

Example
`ifort -ipo -c a.f90 b.f90`

This program will invoke the compiler on the IR saved in the object file and generate a valid object that can be inserted into a library.

Using `xiar` is the same as specifying `xild -lib`.

Mac OS X Only

When using `xilibtool`, specify `-static` to generate static libraries, or specify `-dynamiclib` to create dynamic libraries. For example, the following example command will create a static library named `mylib.a` that includes the `a.o`, `b.o`, and `c.o` objects.

Example

```
xilibtool -static -o mylib.a a.o b.o c.o
```

Alternately, the following example command will create a dynamic library named `mylib.dylib` that includes the `a.o`, `b.o`, and `c.o` objects.

Example

```
xilibtool -dynamic -o mylib.dylib a.o b.o c.o
```

Specifying `xilibtool` is the same as specifying `xild -libtool`.

Windows* Only

Create libraries using `xilib` or `xilink -lib` to create libraries of IPO mock object files and link them on the command line.

For example, assume that you create three mock object files by using a command similar to the following:

Example

```
ifort /c /Qipo a.obj b.obj c.obj
```

Further assume `a.obj` contains the main subprogram. You can enter commands similar to the following to link the objects.

Example

```
xilib -out:main.lib b.obj c.obj

or

xilink -lib -out:main.lib b.obj c.obj
```

You can link the library and the main program object file by entering a command similar to the following:

Example
`xilink -out:result.exe a.obj main.lib`

Requesting Compiler Reports with the xi* Tools

The compiler option `-opt-report` (Linux* and Mac OS* X) or `/Qopt-report` (Windows*) generates optimization reports with different levels of detail. Related compiler options described in Compiler Reports Quick Reference allow you to specify the phase, direct output to a file (instead of stderr), and request reports from all routines with names containing a string as part of their name.

The xi* tools are used with interprocedural optimization (IPO) during the final stage of IPO compilation. You can request compiler reports to be generated during the final IPO compilation by using certain options. The supported xi* tools are:

- Linker tools: `xilink` (Windows) and `xild` (Linux and Mac OS X)
- Library tools: `xilib` (Windows), `xiar` (Linux and Mac OS X), `xilibtool` (Mac OS X)

The following tables lists the compiler report options for the xi* tools. These options are equivalent to the corresponding compiler options, but occur during the final IPO compilation.

Tool Option	Description
`-qopt-report`[=*n*]	Enables optimization report generation with different levels of detail, directed to stderr. Valid values for *n* are 0 through 3. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail.
`-qopt-report-file=`*file*	Generates an optimization report and directs the report output to the specified *file* name. If you omit the path, the file is created in the current directory. To create the file in a different directory, specify the full path to the output file and its file name.
`-qopt-report-phase=`*name*	Specifies the optimization phase *name* to use when generating reports. If you do not specify a phase the compiler defaults to all. You can request a list of all available phase by using the -qopt-report-help option.

Tool Option	Description
`-qopt-report-routine=`*`string`*	Generates reports from all routines with names containing a *`string`* as part of their name. If not specified, the compiler will generate reports on all routines.
`-qopt-report-help`	Displays the optimization phases available.

To understand the compiler reports, use the links provided in Compiler Reports Overview.

Inline Expansion of Functions

Inline Function Expansion

Because inline function expansion does not require that the applications meet the criteria for whole program analysis normally require by IPO, this optimization is one of the primary optimizations used in Interprocedural Optimization (IPO). For function calls that the compiler believes are frequently executed, the Intel® compiler often decides to replace the instructions of the call with code for the function itself.

In the compiler, inline function expansion typically favors relatively small user functions over functions that are relatively large. This optimization improves application performance by performing the following:

- Removing the need to set up parameters for a function call
- Eliminating the function call branch
- Propagating constants

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler can examine the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

Specifying `-ip` (Linux* and Mac OS* X) or `/Qip` (Windows*), single-file IP, causes the compiler to perform inline function expansion for calls to procedures defined within the current source file; in contrast, specifying `-ipo` (Linux and Mac OS X) or `/Qipo` (Windows), multi-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined in other files.

CAUTION. Using the `-ip` and `-ipo` (Linux and Mac OS X) or `/Qip` and `/Qipo` (Windows) options can in some cases significantly increase compile time and code size.

Selecting Routines for Inlining

The compiler attempts to select the routines whose inline expansions will provide the greatest benefit to program performance. The selection is done using the default heuristics. The inlining heuristics used by the compiler differ based on whether or not you use Profile-Guided Optimizations (PGO): `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows).

When you use PGO with `-ip` or `-ipo` (Linux and Mac OS X) or `/Qip` or `/Qipo` (Windows), the compiler uses the following guidelines for applying heuristics:

- The default heuristic focuses on the most frequently executed call sites, based on the profile information gathered for the program.
- The default heuristic always inlines very small functions that meet the minimum inline criteria.

PGO (Windows)

Combining IPO and PGO produces better results than using IPO alone. PGO produces dynamic profiling information that can usually provide better optimization opportunities than the static profiling information used in IPO.

The compiler uses characteristics of the source code to estimate which function calls are executed most frequently. It applies these estimates to the PGO-based guidelines described above. The estimation of frequency, based on static characteristics of the source, is not always accurate.

Avoid using static profile information when combining PGO and IPO; with static profile information, the compiler can only estimate the application performance for the source files being used. Using dynamically generated profile information allows the compiler to accurately determine the real performance characteristics of the application.

Compiler Directed Inline Expansion of User Functions

Without directions from the user, the compiler attempts to estimate what functions should be inlined to optimize application performance. See Criteria for Inline Function Expansion for more information.

The following options are useful in situations where an application can benefit from user function inlining but does not need specific direction about inlining limits. Except where noted, these options are supported on IA-32, Intel® 64, and IA-64 architectures.

Linux* and Mac OS* X	Windows*	Effect
`-inline-level`	`/Ob`	Specifies the level of inline function expansion. Depending on the value

Linux* and Mac OS* X	Windows*	Effect
		specified, the option can disable or enable inlining. By default, the option enables inlining of any function if the compiler believes the function can be inlined. For more information, see the following topic: • `-inline-level` compiler option
`-ip-no-inlining`	`/Qip-no-inlining`	Disables only inlining normally enabled by the following options: • Linux and Mac OS X: `-ip` or `-ipo` • Windows: `/Qip`, `/Qipo`, or `/Ob2` No other IPO optimization are disabled. For more information, see the following topic: • `-ip-no-inlining` compiler option
`-ip-no-pinlining`	`/Qip-no-pinlining`	Disables partial inlining normally enabled by the following options: • Linux and Mac OS X: `-ip` or `-ipo` • Windows: `/Qip` or `/Qipo` No other IPO optimization are disabled.

Linux* and Mac OS* X	Windows*	Effect
		For more information, see the following topic: • -ip-no-pinlining compiler option
-inline-debug-info	/Qinline-debug-info	Keeps source information for inlined functions. The additional source code can be used by the Intel® Debugger track the user-defined call stack while using inlining. To use this option you must also specify an additional option to enable debugging: • Linux: -g • Mac OS X: This option is not supported. • Windows: /debug For more information, see the following topic: • -inline-debug-info compiler option

Developer Directed Inline Expansion of User Functions

In addition to the options that support compiler directed inline expansion of user functions, the compiler also provides compiler options that allow you to more precisely direct when and if inline function expansion occurs.

The compiler measures the relative size of a routine in an abstract value of intermediate language units, which is approximately equivalent to the number of instructions that will be generated. The compiler uses the intermediate language unit estimates to classify routines and functions as relatively small, medium, or large functions. The compiler then uses the estimates to determine when to inline a function; if the minimum criteria for inlining is met and all other things are equal, the compiler has an affinity for inlining relatively small functions and not inlining relative large functions.

The following developer directed inlining options provide the ability to change the boundaries used by the inlining optimizer to distinguish between small and large functions. These options are supported on IA-32, Intel® 64, and IA-64 architectures.

In general, you should use the `-inline-factor` (Linux* and Mac OS* X) and `/Qinline-factor` (Windows*) option before using the individual inlining options listed below; this single option effectively controls several other upper-limit options.

Linux* and Mac OS* X	Windows*	Effect
`-inline-factor`	`/Qinline-factor`	Controls the multiplier applied to all inlining options that define upper limits: `inline-max-size`, `inline-max-total-size`, `inline-max-per-routine`, and `inline-max-per-compile`. While you can specify an individual increase in any of the upper-limit options, this single option provides an efficient means of controlling all of the upper-limit options with a single command. By default, this option uses a multiplier of 100, which corresponds to a factor of 1. Specifying 200 implies a factor of 2, and so on. Experiment with the multiplier carefully. You could increase the upper limits to allow too much inlining, which might result in your system running out of memory. For more information, see the following topic: • `-inline-factor` compiler option

Linux* and Mac OS* X	Windows*	Effect
-inline-forceinline	/Qinline-forceinline	Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so. Typically, the compiler targets functions that have been marked for inlining based on the presence of directives, like DEC$ ATTRIBUTES FORCEINLINE, in the source code; however, all such directives in the source code are treated only as suggestions for inlining. The option instructs the compiler to view the inlining suggestion as mandatory and inline the marked function if it can be done legally. For more information, see the following topic: • -inline-forceinline compiler option
-inline-min-size	/Qinline-min-size	Redefines the maximum size of small routines; routines that are equal to or smaller than the value specified are more likely to be inlined. For more information, see the following topic: • -inline-min-size compiler option

Linux* and Mac OS* X	Windows*	Effect
-inline-max-size	/Qinline-max-size	Redefines the minimum size of large routines; routines that are equal to or larger than the value specified are less likely to be inlined. For more information, see the following topic: • -inline-max-size compiler option
-inline-max-total-size	/Qinline-max-total-size	Limits the expanded size of inlined functions. For more information, see the following topic: • -inline-max-total-size compiler option
-inline-max-per-routine	/Qinline-max-per-routine	Limits the number of times inlining can be applied within a routine. For more information, see the following topic: • -inline-max-per-routine compiler option
-inline-max-per-compile	/Qinline-max-per-compile	Limits the number of times inlining can be applied within a compilation unit. The compilation unit limit depends on the whether or not you specify the -ipo (Linux and Mac OS X) or /Qipo (Windows) option. If you enable IPO, all source files that are part of the compilation are considered

Linux* and Mac OS* X	Windows*	Effect
		one compilation unit. For compilations not involving IPO each source file is considered an individual compilation unit. For more information, see the following topic: • `-inline-max-per-compile` compiler option

Using Profile-Guided Optimization (PGO)

31

Profile-Guided Optimizations Overview

Profile-guided Optimization (PGO) improves application performance by reorganizing code layout to reduce instruction-cache problems, shrinking code size, and reducing branch mispredictions. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

PGO consists of three phases or steps.

1. Step one is to instrument the program. In this phase, the compiler creates and links an instrumented program from your source code and special code from the compiler.
2. Step two is to run the instrumented executable. Each time you execute the instrumented code, the instrumented program generates a dynamic information file, which is used in the final compilation.
3. Step three is a final compilation. When you compile a second time, the dynamic information files are merged into a summary file. Using the summary of the profile information in this file, the compiler attempts to optimize the execution of the most heavily traveled paths in the program.

See Profile-guided Optimization Quick Reference for information about the supported options and Profile an Application for specific details about using PGO from a command line.

PGO enables the compiler to take better advantage of the processor architecture, more effective use of instruction paging and cache memory, and make better branch predictions. PGO provides the following benefits:

- Use profile information for register allocation to optimize the location of spill code.
- Improve branch prediction for indirect function calls by identifying the most likely targets. (Some processors have longer pipelines, which improves branch prediction and translates into high performance gains.)
- Detect and do not vectorize loops that execute only a small number of iterations, reducing the run time overhead that vectorization might otherwise add.

Interprocedural Optimization (IPO) and PGO can affect each other; using PGO can often enable the compiler to make better decisions about function inlining, which increases the effectiveness of interprocedural optimizations. Unlike other optimizations, such as those strictly for size or speed, the results of IPO and PGO vary. This variability is due to the unique characteristics of each program, which often include different profiles and different opportunities for optimizations.

Performance Improvements with PGO

PGO works best for code with many frequently executed branches that are difficult to predict at compile time. An example is the code with intensive error-checking in which the error conditions are false most of the time. The infrequently executed (cold) error-handling code can be relocated so the branch is rarely predicted incorrectly. Minimizing cold code interleaved into the frequently executed (hot) code improves instruction cache behavior.

When you use PGO, consider the following guidelines:

- Minimize changes to your program after you execute the instrumented code and before feedback compilation. During feedback compilation, the compiler ignores dynamic information for functions modified after that information was generated. (If you modify your program the compiler issues a warning that the dynamic information does not correspond to a modified function.)
- Repeat the instrumentation compilation if you make many changes to your source files after execution and before feedback compilation.
- Know the sections of your code that are the most heavily used. If the data set provided to your program is very consistent and displays similar behavior on every execution, then PGO can probably help optimize your program execution.
- Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance then execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Profile-Guided Optimization (PGO) Quick Reference

Profile-Guided Optimization consists of three phases (or steps):

1. Generating instrumented code by compiling with the `-prof-gen` (Linux* OS and Mac OS* X) or `/Qprof-gen` (Windows* OS) option when creating the instrumented executable.
2. Running the instrumented executable, which produces dynamic-information (.dyn) files.
3. Compiling the application using the profile information using the `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) option.

The figure illustrates the phases and the results of each phase.

See Profile an Application for details about using each phase.

The following table lists the compiler options used in PGO:

Linux* and Mac OS* X	Windows*	Effect
`-prof-gen`	`/Qprof-gen`	Instruments a program for profiling to get the execution counts of each basic block. The option is used in phase 1 (instrumenting the code) to instruct the compiler to produce instrumented code for your object files in preparation for instrumented execution. By default, each instrumented execution creates one dynamic-information (dyn) file for each executable and (on Windows OS) one for each DLL invoked by the application. You can specify keywords, such as `-prof-gen=default` (Linux and Mac OS X) or `/Qprof-gen:default` (Windows). The keywords control the amount of source information gathered during phase 2 (run the instrumented executable). The `prof-gen` keywords are: • Specify `default` (or omit the keyword) to request profiling information for use with the `prof-use` option and optimization

Linux* and Mac OS* X	Windows*	Effect
		when the instrumented application is run (phase 2). • Specify `srcpos` or `globdata` to request additional profiling information for the `code coverage` and `test prioritization` tools when the instrumented application is run (phase 2). The phase 1 compilation creates an spi file. • Specify `globdata` to request additional profiling information for data ordering optimization when the instrumented application is run (phase 2). The phase 1 compilation creates an spi file. If you are performing a parallel make, this option will not affect it.
`-prof-use`	`/Qprof-use`	Instructs the compiler to produce a profile-optimized executable and merges available dynamic-information (dyn) files into a pgopti.dpi file. This option implicitly invokes the `profmerge` tool. The dynamic-information files are produced in phase 2 when you run the instrumented executable.

Linux* and Mac OS* X	Windows*	Effect
		If you perform multiple executions of the instrumented program to create additional dynamic-information files that are newer than the current summary pgopti.dpi file, this option merges the dynamic-information files again and overwrites the previous pgopti.dpi file (you can set the environment variable PROF_NO_CLOBBER to prevent the previous dpi file from being overwritten). When you compile with prof-use, all dynamic information and summary information files should be in the same directory (current directory or the directory specified by the `prof-dir` option). If you need to use certain `profmerge` options not available with compiler options (such as specifying multiple directories), use the `profmerge` tool. For example, you can use `profmerge` to create a new summary dpi file before you compile with the `prof-use` option to create the optimized application. You can specify keywords, such as `-prof-gen=weighted` (Linux and Mac OS X) or `/Qprof-gen:weighted` (Windows). If you omit the `weighted` keyword, the merged dynamic-information

Linux* and Mac OS* X	Windows*	Effect
		(dyn) files will be weighted proportionally to the length of time each application execution runs. If you specify the `weighted` keyword, the profiler applies an equal weighting (regardless of execution times) to the dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally. When you use `prof-use`, you can also specify the `prof-file` option to rename the summary dpi file and the `prof-dir` option to specify the directory for dynamic-information (dyn) and summary (dpi) files. Linux: • Using this option with `-prof-func-groups` allows you to control function grouping behavior.
`-no-fnsplit`	`/Qfnsplit-`	Disables function splitting. Function splitting is enabled by the `prof-use` option in phase 3 to improve code locality by splitting routines into different sections: one section to contain the cold or very infrequently executed (cold) code, and one section to contain the rest of the frequently executed (hot)

Linux* and Mac OS* X	Windows*	Effect
		code. You may want to disable function splitting for the following reasons: • Improve debugging capability. In the debug symbol table, it is difficult to represent a split routine, that is, a routine with some of its code in the hot code section and some of its code in the cold code section. • Account for the cases when the profile data does not represent the actual program behavior, that is, when the routine is actually used frequently rather than infrequently. This option is supported on IA-32 architecture for Windows OS and on IA-64 architecture for Windows and Linux OS. It is not supported on other platforms (Intel® 64 architecture, Mac OS X, and Linux on IA-32 architecture). Windows: This option behaves differently on systems based on IA-32 architecture than it does on systems based on IA-64 architecture. IA-32 architecture, Windows OS: • The option completely disables function splitting, placing all the code in one section.

Linux* and Mac OS* X	Windows*	Effect
		IA-64 architecture, Linux and Windows OS: • The option disables the splitting within a routine but enables function grouping, an optimization in which entire routines are placed either in the cold code section or the hot code section. Function grouping does not degrade debugging capability.
-prof-func-groups	/Qprof-func-order	Enables ordering of program routines using profile information when specified with `prof-use` (phase 3). The instrumented program (phase 1) must have been compiled with the `prof-gen` option `srcpos` keyword. Not valid for multi-file compilation with the `ipo` options. Mac OS X: Not supported. IA-64 architecture: Not supported. For more information, see Using Function Ordering, Function Order Lists, Function Grouping, and Data Ordering Optimizations.
-prof-data-order	/Qprof-data-order	Enables ordering of static program data items based on profiling information when specified with `prof-use`. The instrumented program (phase 1) must have been compiled

Linux* and Mac OS* X	Windows*	Effect
		with the `prof-gen` option `srcpos` keyword. Not valid for multi-file compilation with the `ipo` options. Mac OS X: Not supported. For more information, see Using Function Ordering, Function Order Lists, Function Grouping, and Data Ordering Optimizations.
`-prof-src-dir`	`/Qprof-src-dir`	Controls whether full directory information for the source directory path is stored in or read from dynamic-information (dyn) files. When used during phase 1 compilation (`prof-gen`), this determines whether the full path is added into dyn file created during instrumented application execution. When used during `profmerge` or phase 3 compilation (`prof-use`), this determines whether the full path for source file names is used or ignored when reading the dyn or dpi files. Using the default `-prof-src-dir` (Linux and Mac OS X) or `/Qprof-src-dir` (Windows) uses the full directory information and also enables the use of the `prof-src-root` and `prof-src-cwd` options.

Linux* and Mac OS* X	Windows*	Effect
		If you specify `-no-prof-src-dir` (Linux and Mac OS X) or `/Qprof-src-dir` (Windows), only the file name (and not the full path) is stored or used. If you do this, all dyn or dpi files must be in the current directory and the `prof-src-root` and `prof-src-cwd` options are ignored.
`-prof-dir`	`/Qprof-dir`	Specifies the directory in which dynamic information (dyn) files are created in, read from, and stored; otherwise, the dyn files are created in or read from the current directory used during compilation. For example, you can use this option when compiling in phase 1 (`prof-gen` option) to define where dynamic information files will be created when running the instrumented executable in phase 2. You also can use this option when compiling in phase 3 (`prof-use` option) to define where the dynamic information files will be read from and a summary file (dpi) created.
`-prof-src-root` or `-prof-src-cwd`	`/Qprof-src-root` or `/Qprof-src-cwd`	Specifies a directory path prefix for the root directory where the user's application files are stored: • To specify the directory prefix root where source files are stored, specify

Linux* and Mac OS* X	Windows*	Effect
		the `-prof-src-root` (Linux and Mac OS X) or `/Qprof-src-root` (Windows) option. • To use the current working directory, specify the `-prof-src-cwd` (Linux and Mac OS X) or `/Qprof-src-cwd` (Windows) option. This option is ignored if you specify `-no-prof-src-dir` (Linux and Mac OS X) or `/Qprof-src-dir` (Windows).
`-prof-file`	`/Qprof-file`	Specifies file name for profiling summary file. If this option is not specified, the name of the file containing summary information will be pgopti.dpi.
`-prof-gen-sampling`	`/Qprof-gen-sampling`	IA-32 architecture. Prepares application executables for hardware profiling (sampling) and causes the compiler to generate source code mapping information. Mac OS X: This option is not supported.
`-ssp`	`/Qssp`	IA-32 architecture. Enables Software-based Speculative Pre-computation (SSP) optimization. Mac OS X: This option is not supported.

Refer to Quick Reference Lists for a complete listing of the quick reference topics.

Profile an Application

Profiling an application includes the following three phases:

- Instrumentation compilation and linking
- Instrumented execution
- Feedback compilation

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

1. Instrumentation compilation and linking

   Use `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*) to produce an executable with instrumented information included.

Operating System	Commands
Linux and Mac OS X	`ifort -prof-gen -prof-dir/usr/profiled a1.f90 a2.f90 a3.f90` `ifort -oa1 a1.o a2.o a3.o`
Windows	`ifort /Qprof-gen /Qprof-dirc:\profiled a1.f90 a2.f90 a3.f90` `ifort a1.obj a2.obj a3.obj`

   Use the `-prof-dir` (Linux and Mac OS X) or `/Qprof-dir` (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

   The compiler gathers extra information when you use the `-prof-gen=srcpos` (Linux and Mac OS X) or `/Qprof-gen:srcpos` (Windows) option; however, the extra information is collected to provide support only for specific Intel tools, like the code-coverage tool. If you do not expect to use such tools, do not specify `-prof-gen=srcpos` (Linux and Mac OS X) or `/Qprof-gen:srcpos` (Windows); the extended option does not provide better optimization and could slow parallel compile times.

2. Instrumented execution

Run your instrumented program with a representative set of data to create one or more dynamic information files.

Operating System	Command
Linux and Mac OS X	`./a1.out`
Windows	`a1.exe`

Executing the instrumented applications generates dynamic information file that has a unique name and .dyn suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows); the option instructs the compiler to use the generated dynamic information to guide the optimization:

Operating System	Examples
Linux and Mac OS X	`ifort -prof-use -ipo -prof-dir/usr/profiled a1.f90 a2.f90 a3.f90`
Windows	`ifort /Qprof-use /Qipo /Qprof-dirc:\profiled a1.f90 a2.f90 a3.f90`

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations,`-O2` (Linux and Mac OS X) or `/O2` (Windows), for phase 1, and specify more advanced optimizations, `-ipo` (Linux) or `/Qipo` (Windows), during the final (phase 3) compilation. For example, the example shown above used`-O2` (Linux and Mac OS X) or `/O2` (Windows) in step 1 and`-ipo` (Linux or Mac OS X) or `/Qipo` (Windows) in step 3.

NOTE. The compiler ignores the `-ipo` or `-ip` (Linux and Mac OS X) or `/Qipo` or `/Qip` (Windows) option during phase 1 with `-prof-gen` (Linux and Mac OS X) or `/Qprof-gen` (Windows).

PGO Tools

PGO Tools Overview

This section describes the tools that take advantage or support the Profile-guided Optimizations (PGO) available in the compiler.

- code coverage tool
- test prioritization tool
- profmerge tool
- proforder tool

In addition to the tools, this section also contains information on using Software-based Speculative Precomputation, which will allow you to optimize applications using profiling- and sampling-feedback methods on IA-32 architectures.

code coverage Tool

The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- code coverage tool Requirements
- Visually Presenting Code Coverage for an Application
- Excluding Code from Coverage Analysis
- Exporting Coverage Data

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate the in HTML-formatted report and export data in both text-, and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.

The code coverage tool is available on IA-32, Intel® 64, and IA-64 architectures on Linux* and Windows*. The tool is available on IA-32 and Intel® 64 architectures on Mac OS* X.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option, useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.

code coverage tool Requirements

To run the code coverage tool on an application, you must have following items:

- The application sources.
- The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the `-prof-gen=srcpos` (Linux and Mac OS X) or `/Qprof-gen:srcpos` (Windows) options.
- A `pgopti.dpi` file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the profmerge tool. This file is also generated implicitly by the Intel® compilers when compiling an application with `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows) options with available .dyn and .dpi files.

See Understanding Profile-guided Optimization and Example of Profile-guided Optimization for general information on creating the files needed to run this tool.

Using the Tool

The tool uses the following syntax:

Tool Syntax
`codecov [-codecov_option]`

where `-codecov_option` is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in code coverage tools Options (below). If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using `-prof-gen=srcpos` (Linux and Mac OS X) or `/Qprof-gen:srcpos` (Windows).

   This step generates an instrumented executable and a corresponding static profile information (pgopti.spi) file.

2. Run the instrumented application.

   This step creates the dynamic profile information (.dyn) file Each time you run the instrumented application, the compiler generates a unique .dyn file either in the current directory or the directory specified in by prof_dir.

3. Use the profmerge tool to merge all the .dyn files into one .dpi (`pgopti.dpi`) file.

   This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the dpi file needed by the code coverage tool.

   You can use the profmerge tool to merge the .dyn files into a .dpi file without recompiling the application. The profmerge tool can also merge multiple .dpi files into one .dpi file using the `profmerge -a` option. Select the name of the output .dpi file using the `profmerge -prof_dpi` option.

CAUTION. The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

4. Run the code coverage tool. (The valid syntax and tool options are shown below.)

   This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (CODE_COVERAGE.HTML) and a sub-directory (CodeCoverage) in the current directory. Open the file in a web browser to view the reports.

NOTE. Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify .dpi and .spi files to use:

Example: specify .dpi and .spi files

```
codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi
```

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

Example: add contact information

```
codecov -prj myProject -mname JoeSmith -maddr js@company.com
```

This following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name.

Example: export data to text

```
codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt
```

code coverage tool Options

The tool uses the options listed in the table:

Option	Default	Description
`-bcolor` *`color`*	#FFFF99	Specifies the HTML color name for code in the uncovered blocks.
`-beginblkdsbl` *`string`*		Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.

Option	Default	Description
-ccolor *color*	#FFFFFF	Specifies the HTML color name or code of the covered code.
-comp *file*		Specifies the file name that contains the list of files being (or not) displayed.
-counts		Generates dynamic execution counts.
-demang		Demangles both function names and their arguments.
-dpi *file*	pgopti.dpi	Specifies the file name of the dynamic profile information file (.dpi).
-endblkdsbl *string*		Specifies the comment that marks the end of the code fragment to be ignored by the coverage tool.
-fcolor *color*	#FFCCCC	Specifies the HTML color name for code of the uncovered functions.
-help, -h		Prints tool option descriptions.
-icolor *color*	#FFFFFF	Specifies the HTML color name or code of the information lines, such as basic-block markers and dynamic counts.
-maddr *string*	Nobody	Sets the email address of the web-page owner

Option	Default	Description
-mname *string*	Nobody	Sets the name of the web-page owner.
-nopartial		Treats partially covered code as fully covered code.
-nopmeter		Turns off the progress meter. The meter is enabled by default.
-onelinedsbl string		Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.
-pcolor *color*	#FAFAD2	Specifies the HTML color name or code of the partially covered code.
-prj *string*		Sets the project name.
-ref		Finds the differential coverage with respect to ref_dpi_file.
-spi *file*	pgopti.spi	Specifies the file name of the static profile information file (.spi).
-srcroot *dir*		Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.

Option	Default	Description
-txtbcvrg *file*		Export block-coverage for covered functions as text format. The file parameter must be in the form of a valid file name.
-txtbcvrgfull *file*		Export block-coverage for entire application in text and HTML formats. The file parameter must be in the form of a valid file name.
-txtdcg *file*		Generates the dynamic call-graph information in text format. The file parameter must be in the form of a valid file name.
-txtfcvrg *file*		Export function coverage for covered function in text format. The file parameter must by in the form of a valid file name.
-ucolor *color*	#FFFFFF	Specifies the HTML color name or code of the unknown code.
-xcolor *color*	#90EE90	Specifies the HTML color of the code ignored.
-xmlbcvrg *file*		Export the block-coverage for the covered function in XML format. The file parameter must by in the form of a valid file name.

Option	Default	Description
`-xmlbcvrgfull` *file*		Export function coverage for entire application in XML format in addition to HTML output. The file parameter must be in the form of a valid file name.
`-xmlfcvrg` *file*		Export function coverage for covered function in XML format. The file parameter must be in the form of a valid file name.

Visually Presenting Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application's critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- Top level (for a group of selected modules)
- Individual module source views

Top Level Coverage

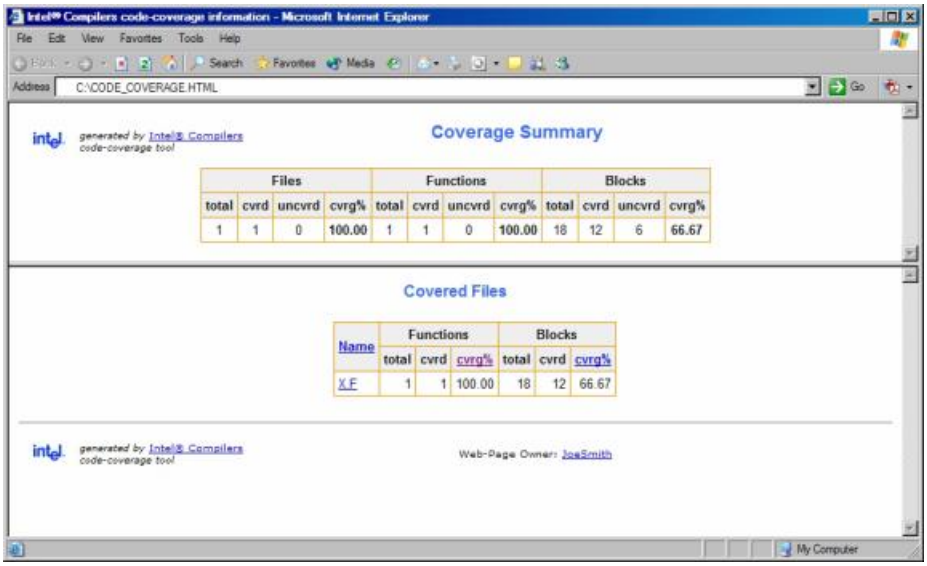
The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.

- By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:
  - basic block coverage
  - function coverage
  - function name

By default, the code coverage tool generates a single HTML file (CODE_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.



The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. So, just by one click, you can see the least-covered function in the list and by another click the browser displays the body of the function. You can scroll down in the source view and browse through the function body.

Individual Module Source View

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

- Number of blocks within uncovered functions
- Block coverage in the case of covered functions
- Function names

Setting the Coloring Scheme for the Code Coverage

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

Category	Default	Description
Covered code	#FFFFFF	Indicates code was exercised by the tests. You can override the default color with the `-ccolor` tool option.
Uncovered basic block	#FFFF99	Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed

Category	Default	Description
		during the tests. You can override the default color with the `-bcolor` tool option.
Uncovered function	#FFCCCC	Indicates functions that were never called during the tests. You can override the default color with the `-fcolor` tool option.
Partially covered code	#FAFAD2	Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the `-pcolor` tool option.
Ignored code	#90EE90	Indicates code that was specifically marked to be ignored. You can override this default color using the `-xcolor` tool option.
Information lines	#FFFFFF	Indicates basic-block markers and dynamic counts. You can override the default color with the `-icolor` tool option.
Unknown	#FFFFFF	Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the `-ucolor` tool option.

The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

NOTE. You need to interpret the colors in the context of the code. For instance, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks.

Dynamic Counters

The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the `-counts` option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.

If more than one basic block is generated for the code at a source position (for example, for macros), then the total number of such blocks and the number of the blocks that were executed are also displayed in front of the execution count. For example, line 11 in the code is an `IF` statement:

Example

```
11   IF ((N .EQ. 1).OR. (N .EQ. 0))
     ^ 10 (1/2)
12      PRINT N
        ^ 7
```

The coverage lines under code lines 11 and 12 contain the following information:

- The `IF` statement in line 11 was executed 10 times.
- Two basic blocks were generated for the `IF` statement in line 11.

- Only one of the two blocks was executed, hence the partial coverage color.
- Only seven out of the ten times variable n had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as one entity. In such cases, it is necessary to assume that all blocks generated for one source position are covered when at least one of the blocks is covered. This assumption can be configured with the `-nopartial` option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted accordingly. The code lines 11 and 12 indicate that the `print` statement in line 12 was covered. However, only one of the conditions in line 11 was ever true. With the `-nopartial` option, the tool treats the partially covered code (like the code on line 11) as covered.

Differential Coverage

Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run and a new run identifying the code that is covered by the new run but not covered by the reference run. Use this feature to find the portion of the applications code that is not covered by the applications tests but is executed when the application is run by a customer. It can also be used to find the incremental coverage impact of newly added tests to an applications test space.

Generating Reference Data

Create the dynamic profile information for the reference data, which can be used in differential coverage reporting later, by using the `-ref` option. The following command demonstrate a typical command for generating the reference data:

Example: generating reference data
`codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi`

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new run but missed in the reference run. In such cases, the tool shows only the modules that included the code that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code that has the same coverage property (covered or not covered) on both runs is considered as covered code. Otherwise, if the new run indicates that the code was executed while in the reference run the code was not executed, then the code is treated as uncovered. On the other hand, if the code is covered in the reference run but not covered in the new run, the differential-coverage source view shows the code as covered.

Running Differential Coverage

To run the code coverage tool for differential coverage, you must have the application sources, the .spi file, and the .dpi file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following begin the process of differential coverage analysis:

Example
`codecov -prj Project_Name -spi pgopti.spi -dpi pgopti.dpi`

Specify the .dpi and .spi files using the `-spi` and `-dpi` options.

Excluding Code from Coverage Analysis

The code coverage tool allows you to exclude portions of your code from coverage analysis. This ability can be useful during development; for example, certain portions of code might include functions used for debugging only. The test case should not include tests for functionality that will unavailable in the final application.

Another example of code that can be excluded is code that might be designed to deal with internal errors unlikely to occur in the application. In such cases, not having a test case lack of a test case is preferred. You might want to ignore infeasible (dead) code in the coverage analysis. The code coverage tool provides several options for marking portions of the code infeasible (dead) and ignoring the code at the file level, function level, line level, and arbitrary code boundaries indicated by user-specific comments. The following sections explain how to exclude code at different levels.

Including and Excluding Coverage at the File Level

The code coverage tool provides the ability to selectively include or exclude files for analysis. Create a component file and add the appropriate string values that indicate the file and directory name for code you want included or excluded. Pass the file name as a parameter of the `-comp` option. The following example shows the general command:

Example: specifying a component file
`codecov -comp file`

where *`file`* is the name of a text file containing strings that ask as file and directory name masks for including and excluding file-level analysis. For example, assume that the following:

- You want to include all files with the string "source" in the file name or directory name.

- You create a component text file named `myComp.txt` with the selective inclusion string.

Once you have a component file, enter a command similar to the following:

Example

```
codecov -comp myComp.txt
```

In this example, individual files name including the string "source" (like source1.f and source2.f) and files in directories where the name contains the string "source" (like source/file1.f and source2\file2.f) are include in the analysis.

Excluding files is done in the same way; however, the string must have a tilde (~) prefix. The inclusion and exclusion can be specified in the same component file.

For example, assume you want to analyze all individual files or files contained in a directory where the name included the string "source", and you wanted to exclude all individual file and files contained in directories where the name included the string "skip". You would add content similar to the following to the component file (`myComp.txt`) and pass it to the `-comp` option:

Example: inclusion and exclusion strings

```
source
~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file will instruct the tool to include individual files where the name contains "source" (like source1.f and source2.f) and directories where the name contains "source" (like source/file1.f and source2\file2.f), and exclude any individual files where the name contains "skip" (like skipthis1.f and skipthis2.f) or directories where the name contains "skip" (like skipthese1\debug1.f and skipthese2\debug2.f).

Excluding Coverage at the Line and Function Level

You can mark individual lines for exclusion my passing string values to the `-onelinedsbl` option. For example, assume that you have some code similar to the following:

Sample code

```
print*, "ERROR: n  = ", n  ! NO_COVER
print*, "       n2 = ", n2  ! INF IA-32 architecture
```

If you wanted to exclude all functions marked with the comments NO_COVER or INF IA-32 architecture, you would enter a command similar to the following.

Example

```
codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above.

Sample code

```
subroutine dumpInfo (n)
integer n ! NO_COVER
...
end subroutine
```

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the `-onelinedsbl` and `-xcolor` options. The following example commands demonstrate the combination:

Example: combining tool options

```
codecov -onelinedsbl INF -xcolor lightgreen
codecov -onelinedsbl INF -xcolor #CCFFCC
```

Excluding Code by Defining Arbitrary Boundaries

The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.

Use the -beginblkdsbl and -endblkdsbl options to mark the beginning and end, respectively, of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

For example assume that you have the following code:

Sample code

```
integer n, n2
n = 123
n2 = n*n
if (n2 .lt. 0) then
! /* BINF */
  print*, "ERROR: n  = ", n
  print*, "       n2 = ", n2
! // EINF
else if (n2 .eq. 0) then
  print*, "zero: n = ", n, " n2 = ", n2
else
  print*, "positive: n = ", n, " n2 = ", n2
endif
end
```

The following example commands demonstrate how to use the -beginblkdsbl option to mark the beginning and the -endblkdsbl option to mark the end of code to exclude from the sample shown above.

Example: arbitrary code marker commands

```
codecov -xcolor #ccFFCC -beginblkdsbl BINF -endblkdsbl EINF
codecov -xcolor #ccFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```

Notice that you can combine these options in combination with the `-xcolor` option.

Exporting Coverage Data

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool

- **Quick export:** The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The `-xmlfcvrg`, `-txtfcvrg`, `-xml-bcvrg` and `-txtbcvrg` options support the first method.
- **Combined export:** The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The `-xmlbcvrgfull` and `-txtbcvrgfull` options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

Quick Export

The profile of covered functions of an application can be exported quickly using the `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg`, and `-txtbcvrg` options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

Example: quick export of function data

```
codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvrg.xml
```

The resulting report will show how many times each function was executed and the total number of blocks of each function together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report.

XML-formatted report example

```
<PROJECT name = "test1">
   <MODULE name = "D:\SAMPLE.F">
      <FUNCTION name="f0" freq="2">
         <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
      </FUNCTION>
      ...
   </MODULE>
   <MODULE name = "D:\SAMPLE2.F">
      ...
   </MODULE>
</PROJECT>
```

In the above example, we note that function f0, which is defined in file sample.f, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33% basic block coverage.

You can also export the data in text format using the `-txtfcvrg` option. The generated text report, using this option, for the above example would be similar to the following example:

Text-formatted report example

```
Covered Functions in File: "D:\SAMPLE.F"
"f0"    2       6       5        83.33
"f1"    1       6       4        66.67
"f2"    1       6       3        50.00
...
```

In the text formatted version of the report, the each line of the report should be read in the following manner:

Column 1	Column 2	Column 3	Column 4	Column 5
function name	execution frequency	line number of the start of the function definition	column number of the start of the function definition	percentage of basic-block coverage of the function

Additionally, the tool supports exporting the block level coverage data using the `-xmlbcvrg` option. For example, enter a command similar to the following to generate a report of covered blocks in XML formatted output:

Example: quick export of block data to XML

```
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```

The example command shown above would generate XML-formatted results similar to the following:

XML-formatted report example

```
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.cF90">
    <FUNCTION name="f0" freq="2">
    ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1"> </INSTANCE>
      </BLOCK>
      <BLOCK line="12" col="3">
        <INSTANCE id="1" freq="2"> </INSTANCE>
        <INSTANCE id="2" freq="1"> </INSTANCE>
      </BLOCK>
```

In the sample report, notice that one basic block is generated for the code in function f0 at the line 11, column 2 of the file sample.f90. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column

3 of file. One of these blocks, which has id = 1, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the `-txtbcvrg` option.

Combined Exports

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.

Use the `-xmlbcvrgfull` and `-txtbcvrgfull` options to generate reports in all supported formatted in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

Dynamic Call Graphs

Using the `-txtdcg` option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

test prioritization Tool

The test prioritization tool enables the profile-guided optimizations on IA-32, Intel® 64, and IA-64 architectures, on Linux* and Windows*, to select and prioritize test for an application based on prior execution profiles. The tool is available on IA-32 and Intel® 64 architectures on Mac OS* X.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- Features and benefits
- Requirements and syntax
- Usage model
- Tool options
- Running the tool

Features and Benefits

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application: the tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing: instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests' execution time.

See Understanding Profile-guided Optimization and Example of Profile-guided Optimization for general information on creating the files needed to run this tool.

test prioritization Tool Requirements

The test prioritization tool needs the following items to work:

- The .spi file generated by Intel® compilers when compiling the application for the instrumented binaries with the `-prof-gen=srcpos` (Linux* and Mac OS* X) or `/Qprof-gen:srcpos` (Windows*) option.
- The .dpi files generated by the profmerge tool as a result of merging the dynamic profile information .dyn files of each of the application tests. (Run the profmerge tool on all .dyn files that are generated for each individual test and name the resulting .dpi in a fashion that uniquely identifies the test.)

CAUTION. The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code;

- User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:
- Name each test .dpi file so the file names uniquely identify each test.

- Create a .dpi list file, which is a text file that contains the names of all .dpi test files.

  Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.

  For example: `Test1.dpi 00:00:60:35` states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.

  The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

The tool uses the following general syntax:

Tool Syntax
`tselect -dpi_list` *file*

`-dpi_list` is a required tool option that sets the path to the list file containing the list of the all .dpi files. All other tool commands are optional.

NOTE. Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

Usage Model

The following figure illustrates a typical test prioritization tool usage model.

test prioritization tool Options

The tool uses the options that are listed in the following table:

Option	Default	Description
`-help`		Prints tool option descriptions.
`-dpi_list` *file*		Required. Specifies the file name of the file that contains the names of the dynamic

Option	Default	Description
		profile information (`.dpi`) files. Each line of the file must contain only one `.dpi` file name, which can be optionally followed by its execution time. The name must uniquely identify the test.
`-spi` *file*	`pgopti.spi`	Specifies the file name of the static profile information file (.SPI).
`-o` *file*		Specifies the file name of the output report file.
`-comp` *file*		Specifies the file name that contains the list of files of interest.
`-cutoff` *file*		Instructs the tool to terminate when the cumulative block coverage reaches a preset percentage, as specified by `value`, of pre-computed total coverage. `value` must be greater than 0.0 (for example, 99.00) but not greater than 100. `value` can be set to 100.
`-nototal`		Instructs the tool to ignore the pre-compute total coverage process.
`-mintime`		Instructs the tool to minimize testing execution time. The execution time of each test must be provided on the

Option	Default	Description
		same line of `dpi_list` file, after the test name in dd:hh:mm:ss format.
`-srcbasedir` *dir*		Specifies a different top level project directory than was used during compiler instrumentation run with the `prof-src-root` compiler option to support relative paths to source files in place of absolute paths.
`-verbose`		Instructs the tool to generate more logging information about program progress.

Running the tool

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

Example
`set prof-dir=c:\myApp\prof-dir`

2. Compile the program and generate instrumented binary by issuing commands similar to the following:

Operating System	Command
Linux and Mac OS X	`ifort -prof-gen=srcpos myApp.f90`
Windows	`ifort /Qprof-gen:srcpos myApp.f90`

This commands shown above compiles the program and generates instrumented binary `myApp` as well as the corresponding static profile information `pgopti.spi`.

3. Make sure that unrelated `.dyn` files are not present by issuing a command similar to the following:

Example
`rm prof-dir \*.dyn`

4. Run the instrumented files by issuing a command similar to the following:

Example
`myApp < data1`

   The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension `.dyn` in the directory specified by the `-prof-dir` step above.

5. Merge all `.dyn` file into a single file by issuing a command similar to the following:

Example
`profmerge -prof_dpi Test1.dpi`

   The profmerge tool merges all the .dyn files into one file (`Test1.dpi`) that represents the total profile information of the application on Test1.

6. Again make sure there are no unrelated .dyn files present a second time by issuing a command similar to the following:

Example
`rm prof-dir \*.dyn`

7. Run the instrumented application and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified the `prof-dir` step above by issuing a command similar to the following:

Example
`myApp < data2`

8. Merge all .dyn files into a single file, by issuing a command similar to the following

Example
`profmerge -prof_dpi Test2.dpi`

At this step, the profmerge tool merges all the .dyn files into one file (`Test2.dpi`) that represents the total profile information of the application on Test2.

9. Make sure that there are no unrelated .dyn files present for the final time, by issuing a command similar to the following:

Example
`rm prof-dir \*.dyn`

10. Run the instrumented application and generates one or more new dynamic profile information files that have an extension .dyn in the directory specified by `-prof-dir` by issuing a command similar to the following:

Example
`myApp < data3`

11. Merge all .dyn file into a single file, by issuing a command similar to the following:

Example
`profmerge -prof_dpi Test3.dpi`

At this step, the profmerge tool merges all the .dyn files into one file (`Test3.dpi`) that represents the total profile information of the application on Test3.

12. Create a file named `tests_list` with three lines. The first line contains `Test1.dpi`, the second line contains `Test2.dpi`, and the third line contains `Test3.dpi`.

Tool Usage Examples

When these items are available, the test prioritization tool may be launched from the command line in `prof-dir` directory as described in the following examples.

Example 1: Minimizing the Number of Tests

The following example describes how minimize the number of test runs.

Example Syntax

```
tselect -dpi_list tests_list -spi pgopti.spi
```

where the `-spi` option specifies the path to the .spi file.

The following sample output shows typical results.

Sample Output

```
Total number of tests   =  3
Total block coverage    ~  52.17
Total function coverage ~  50.00
 num  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
 ---  --------  --------  --------  -------------------
   1   87.50     45.65     37.50    Test3.dpi
   2   100.50    52.17     50.00    Test2.dpi
```

In this example, the results provide the following information:

- By running all three tests, we achieve 52.17% block coverage and 50.00% function coverage.
- Test3 by itself covers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, we achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

Example 2: Minimizing Execution Time

Suppose we have the following execution time of each test in the `tests_list` file:

Sample Output

```
Test1.dpi 00:00:60:35
Test2.dpi 00:00:10:15
Test3.dpi 00:00:30:45
```

The following command minimizes the execution time by passing the `-mintime` option:

Sample Syntax

```
tselect -dpi_list tests_list -spi pgopti.spi -mintime
```

The following sample output shows possible results:

Sample Output

```
Total number of tests   =  3
Total block coverage    ~  52.17
Total function coverage ~  50.00
Total execution time    =  1:41:35
 num  elaspedTime  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
 ---  -----------  --------  --------  --------  ------------------
   1   10:15        75.00     39.13     25.00    Test2.dpi
   2   41:00        100.00    52.17     50.00    Test3.dpi
```

In this case, the results indicate that the running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests is based on minimizing time (first Test2, then Test3) could be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

Using Other Options

The `-cutoff` option enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to the option:

Example

```
tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```

If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The `-nototal` option enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

profmerge and proforder Tools

profmerge Tool

Use the profmerge tool to merge dynamic profile information (.dyn) files and any specified summary files (.dpi). The compiler executes profmerge automatically during the feedback compilation phase when you specify `-prof-use` (Linux* and Mac OS* X) or `/Qprof-use` (Windows*).

The command-line usage for profmerge is as follows:

Syntax
`profmerge [-prof_dir dir_name]`

The tool merges all .dyn files in the current directory, or the directory specified by `-prof_dir`, and produces a summary file: `pgopti.dpi`.

NOTE. The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options ompiler options (for example `-prof-dir` or `/Qprof-dir`) to join words. Also, on Windows* OS systems, the tool options are preceded by a hyphen ("-") unlike Windows compiler options, which are preceded by a forward slash ("/").

You can use profmerge tool to merge .dyn files into a .dpi file without recompiling the application. Thus, you can run the instrumented executable file on multiple systems to generate dyn files, and optionally use profmerge with the `-prof_dpi` option to name each summary dpi file created from the multiple dyn files.

Since the profmerge tool merges all the .dyn files that exist in the given directory, make sure unrelated .dyn files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

profmerge Options

The profmerge tool supports the following options:

Tool Option	Description
`-help`	Lists supported options.
`-nologo`	Disables version information. This option is supported on Windows* only.
`-exclude_funcs` *functions*	Excludes functions from the profile. The list items must be separated by a comma (","); you can use a period (".") as a wild card character in function names.
`-prof_dir` *dir*	Specifies the directory from which to read .dyn and .dpi files , and write the .dpi file. Alternatively, you can set the environment variable PROF_DIR.
`-prof_dpi` *file*	Specifies the name of the .dpi file being generated.
`-prof_file` *file*	Merges information from file matching: dpi_file_and_dyn_tag.
`-dump`	Displays profile information.
`-src_old` *dir* `-src_new` *dir*	Changes the directory path stored within the .dpi file.
`-src_no_dir`	Uses only the file name and not the directory name when reading dyn/dpi records. If you specify `-src_no_dir`, the directory name of the source file will be ignored when deciding

Tool Option	Description
	which profile data records correspond to a specific application routine, and the `-src-root` option is ignored.
`-src-root` *dir*	Specifies a directory path prefix for the root directory where the user's application files are stored. This option is ignored if you specify `-src_no_dir`.
`-a` *file1.dpi ... fileN.dpi*	Specifies and merges available .dpi files.
`-verbose`	Instructs the tool to display full information during merge.
`-weighted`	Instructs the tool to apply an equal weighting (regardless of execution times) to the dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.

Relocating source files using profmerge

The Intel® compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (.dpi) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading dyn/dpi file records by specifying the `profmerge` option `-src_no_dir`. This `profmerge` option is the same as the compiler option `-no-prof-src-dir` (Linux and Mac OS X) and `/Qprof-src-dir-` (Windows).

To enable the movement of application sources, as well as the sharing of profile summary files, you can use the `profmerge` option `-src-root` to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair `-src_old -src_new` to modify the data in an existing summary dpi file. For example:

Example: relocation command syntax
`profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>`

where *<dir1>* is the full path to dynamic information file (.dpi), *<dir2>* is the old full path to source files, and *<dir3>* is the new full path to source files. The example command (above) reads the `pgopti.dpi` file, in the location specified in *<dir1>*. For each routine represented in the `pgopti.dpi` file, whose source path begins with the *<dir2>* prefix, profmerge replaces that prefix with *<dir3>*. The `pgopti.dpi` file is updated with the new source path information.

You can run profmerge more than once on a given `pgopti.dpi` file. For example, you may need to do this if the source files are located in multiple directories:

Operating System	Command Examples
Linux and Mac OS X	`profmerge -prof_dir -src_old /src/prog_1 -src_new /src/prog_2` `profmerge -prof_dir -src_old /proj_1 -src_new /proj_2`
Windows	`profmerge -src_old "c:/program files" -src_new "e:/program files"` `profmerge -src_old c:/proj/application -src_new d:/app`

In the values specified for `-src_old` and `-src_new`, uppercase and lowercase characters are treated as identical. Likewise, forward slash (`/`) and backward slash (`\`) characters are treated as identical.

NOTE. Because the source relocation feature of profmerge modifies the `pgopti.dpi` file, consider making a backup copy of the file before performing the source relocation.

proforder Tool

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the `/ORDER` linker option. The tool uses the following syntax:

Syntax
`proforder [-prof_dir dir] [-o file]`

where *dir* is the directory containing the profile files (`.dpi` and `.spi`), and *file* is the optional name of the function order list file. The default name is `proford.txt` .

NOTE. The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example `-prof-dir` or `/Qprof-dir`) to join words. Also, on Windows* OS systems, the tool options are preceded by a hyphen ("-") unlike Windows compiler options, which are preceded by a forward slash ("/").

proforder Options

The proforder tool supports the following options:

Tool Option	Default	Description
`-help`		Lists supported options.
`-nologo`		Disables version information. This option is supported on Windows* only.
`-omit_static`		Instructs the tool to omit static functions from function ordering.
`-prof_dir` *dir*		Specifies the directory where the .spi and .dpi file reside.
`-prof_dpi` *file*		Specifies the name of the .dpi file.
`-prof_file` *string*		Selects the .dpi and .spi files that include the substring value in the file name matching the values passed as string.

Tool Option	Default	Description
`-prof_spi` *file*		Specifies the name of the .spi file.
`-o` *file*	`proford.txt`	Specifies an alternate name for the output file.

Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations

Instead of doing a full multi-file interprocedural build of your application by using the compiler option `-ipo` (Linux* OS) or `/Qipo` (Windows* OS), you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the procedures and data in your application. These optimizations are not supported on Mac OS* X systems.

The following table lists each optimization, the type of procedures or global data it applies to, and the operating systems and architectures that it is supported on.

Optimization	Type of Procedure or Data	Supported OS and Architectures
Function Order Lists: Specifies the order in which the linker should link the non-static routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging. Also see Comparison of Function Order Lists and IPO Code Layout.	`EXTERNAL` procedures and library procedures only (not other types of static procedures).	Windows OS: IA-32, Intel® 64, and IA-64 architectures Linux OS: not supported
Function Grouping: Specifies that the linker should place the extern and static routines (procedures) of your program into hot or cold program sections. This optimization can improve	`EXTERNAL` procedures and static procedures only (not library procedures).	Linux OS: IA-32 and Intel 64 architectures Windows OS: not supported

Optimization	Type of Procedure or Data	Supported OS and Architectures
application performance by improving code locality and reduce paging. **Function Ordering:** Enables ordering of static and extern routines using profile information. Specifies the order in which the linker should link the routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging. **Data Ordering:** Enables ordering of static global data items (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) based on profiling information. Specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.	`EXTERNAL` procedures and static procedures only (not library procedures) Static global data (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) only	Linux and Windows OS: IA-32, Intel 64, and IA-64 architectures Linux and Windows OS, IA-32, Intel 64, and IA-64 architectures

You can use only one of the function-related ordering optimizations listed above. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the `prof-gen` option keyword `globdata` (needed for Data Ordering) instead of `srcpos` (needed for function-related ordering).

The following sections show the commands needed to implement each of these optimizations: function order list, function grouping, function ordering, and data ordering. For all of these optimizations, omit the `-ipo` (Linux* OS) or `/Qipo` (Windows OS) or equivalent compiler option.

Generating a Function Order List (Windows OS)

This section provides an example of the process for generating a function order list. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`. Additionally, assume you have created a directory for the profile data files called `c:\profdata`. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the `/Qprof-gen:srcpos` option. Use the `/Qprof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

Example commands
`ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90`

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Example commands
`myprog.exe`

3. Before this step, copy all .dyn and .dpi files into the same directory. Merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the `pgopti.dpi` file. Use the `/prof_dir` option to specify the directory location of the .dyn files.

Example commands
`profmerge /prof_dir c:\profdata`

4. Generate the function order list using the proforder tool. (By default, the function order list is produced in the file `proford.txt`.)

Example commands
`proforder /prof_dir c:\profdata /o myprog.txt`

5. Compile the application with the generated profile feedback by specifying the `ORDER` option to the linker. Use the `/Qprof-dir` option to specify the directory location of the profile files.

Example commands
`ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /link /ORDER:@MYPROG.txt`

Using Function Grouping (Linux OS)

This section provides a general example of the process for using the function grouping optimization. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`. Additionally, assume you have created a directory for the profile data files called `profdata`. You would enter commands similar to the following to use a function grouping for your Linux application.

1. Compile your program using the `-prof-gen` option. Use the `-prof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

Example commands
`ifort -o myprog -prof-gen -prof-dir ./profdata file1.f90 file2.f90`

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Example commands
`./myprog`

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the `pgopti.dpi` file.

4. Compile the application with the generated profile feedback by specifying the `-prof-func-group` option to request the function grouping as well as the `-prof-use` option to request feedback compilation. Again, use the `-prof-dir` option to specify the location of the profile files.

Example commands
`ifort /exe:myprog file1.f90 file2.f90 -prof-func-group -prof-use -prof-dir ./profdata`

Using Function Ordering

This section provides an example of the process for using the function ordering optimization. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`. Additionally, assume you have created a directory for the profile data files called `c:\profdata` (on Windows) or `./profdata` (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.

1. Compile your program using the `-prof-gen=srcpos` (Linux) or `/Qprof-gen:srcpos` (Windows) option. Use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

Operating System	Example commands
Linux	`ifort -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.f90 file2.f90`
Windows	`ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90`

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Operating System	Example commands
Linux	`./myprog`

Operating System	Example commands
Windows	`myprog.exe`

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `-prof-func-order` (Linux) or `/Qprof-func-order` (Windows) option to request the function ordering as well as the `-prof-use` (Linux) or `/Qprof-use` (Windows) option to request feedback compilation. Again, use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the location of the profile files.

Operating System	Example commands
Linux	`ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-func-order -prof-use`
Windows	`ifort /exe:myprog /Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-func-order /Qprof-use`

Using Data Ordering

This section provides an example of the process for using the data order optimization. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`. Additionally, assume you have created a directory for the profile data files called `c:\profdata` (on Windows) or `./profdata` (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the `-prof-gen=globdata` (Linux) or `/Qprof-gen:globdata` (Windows) option. Use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

Operating System	Example commands
Linux	`ifort -o myprog -prof-gen=globdata -prof-dir ./profdata file1.f90 file2.f90`
Windows	`ifort /exe:myprog /Qprof-gen:globdata /Qprof-dir c:\profdata file1.f90 file2.f90`

2. Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Operating System	Example commands
Linux	`./myprog`
Windows	`myprog.exe`

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `-prof-data-order` (Linux) or `/Qprof-data-order` option to request the data ordering as well as the `-prof-use` (Linux) or `/Qprof-use` (Windows) option to request feedback compilation. Again, use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the location of the profile files.

Operating System	Example commands
Linux	`ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-data-order -prof-use`
Windows	`ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-data-order /Qprof-use`

Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the `/Qipo` (Windows) compiler option

Each method has its advantages. A function order list, created with proforder, lets you optimize the layout of non-static functions: that is, external and library functions whose names are exposed to the linker.

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

Function Order List Effects

Function Type	IPO Code Layout	Function Ordering with proforder
Static	X	No effect
Extern	X	X
Library	No effect	X

Function Order List Usage Guidelines (Windows*)

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.
-

PGO API Support

API Support Overview

The Profile Information Generation Support (Profile IGS) lets you control the generation of profile information during the instrumented execution phase of profile-guided optimizations.

A set of functions and an environment variable comprise the Profile IGS. The remaining topics in this section describe the associated functions and environment variables.

The compiler sets a `define` for `_PGO_INSTRUMENT` when you compile with either `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*). Without instrumentation, the Profile IGS functions cannot provide PGO API support.

NOTE. The Profile IGS functions are written in C. Fortran applications must call C/C++ functions.

Normally, profile information is generated by an instrumented application when it terminates by calling the standard `exit()` function.

To ensure that profile information is generated, the functions described in this section may be necessary or useful in the following situations:

- The instrumented application exits using a non-standard exit routine.
- The instrumented application is a non-terminating application: `exit()` is never called.
- The application requires control of when the profile information is generated.

You can use the Profile IGS functions in your application by including a header file at the top of any source file where the functions may be used.

Example
`INCLUDE "pgouser.h"`

The Profile IGS Environment Variable

The environment variable for Profile IGS is `INTEL_PROF_DUMP_INTERVAL`. This environment variable may be used to initiate Interval Profile Dumping in an instrumented user application.

See Also

- PGO API Support
- _PGOPTI_Set_Interval_Prof_Dump()

PGO Environment Variables

The environment variables determine the directory in which to store dynamic information files, control the creation of one or multiple dyn files to collect profiling information, and determine whether to overwrite `pgopti.dpi`.

The environment variables are described in the table below.

Variable	Description
INTEL_PROF_DUMP_CUMULATIVE	When using interval profile dumping (initiated by INTEL_PROF_DUMP_INTERVAL or the function _PGOPTI_Set_Interval_Prof_Dump) during the execution of an instrumented user application, allows creation of a single .dyn file to contain profiling information instead of multiple .dyn files. If this environment variable is not set, executing an instrumented user application creates a new .dyn file for each interval. Setting this environment variable is useful for applications that do not terminate or those that terminate abnormally (bypass the normal exit code).
INTEL_PROF_DUMP_INTERVAL	Initiates interval profile dumping in an instrumented user application. This environment variable may be used to initiate Interval Profile Dumping in an instrumented application. See Interval Profile Dumping for more information.
PROF_DIR	Specifies the directory in which dynamic information files are created. This variable applies to all three phases of the profiling process.
PROF_DUMP_INTERVAL	Deprecated. Please use INTEL_PROF_DUMP_INTERVAL instead.
PROF_NO_CLOBBER	Alters the feedback compilation phase slightly. By default, during the feedback compilation phase, the compiler merges data from all dynamic information files and creates a new pgopti.dpi file if the .dyn files are newer than an existing pgopti.dpi file.

Variable	Description
	When this variable is set the compiler does not overwrite the existing `pgopti.dpi` file. Instead, the compiler issues a warning. You must remove the `pgopti.dpi` file if you want to use additional dynamic information files.

See the appropriate operating system documentation for instructions on how to specify environment variables and their values.

Dumping Profile Information

The `_PGOPTI_Prof_Dump_All()` function dumps the profile information collected by the instrumented application. The prototype of the function call is listed below.

Syntax

```
void _PGOPTI_Prof_Dump_All(void);
```

An older version of this function, `_PGOPTI_Prof_Dump()`, which will also dump profile information is still available; the older function operates much like `_PGOPTI_Prof_Dump_All()`, except on Linux when used in connection with shared libraries (.so) and `_exit()` to terminate a program. When `_PGOPTI_Prof_Dump_All()` is called before `_exit()` to terminate the program, the new function insures that a .dyn file is created for all shared libraries needing to create a .dyn file. Use `_PGOPTI_Prof_Dump_All()` on Linux to insure portability and correct functionality.

The profile information is generated in a .dyn file (generated in phase 2 of PGO).

Recommended usage

Insert a single call to this function in the body of the function which terminates the user application. Normally, `_PGOPTI_Prof_Dump_All()` should be called just once. It is also possible to use this function in conjunction with `_PGOPTI_Prof_Reset()` function to generate multiple .dyn files (presumably from multiple sets of input data).

Example

```
! Selectively collect profile information
! for the portion of the application
! involved in processing input data.
input_data = get_input_data()
do while (input_data)
  call _PGOPTI_Prof_Reset()
  call process_data(input_data)
  call _PGOPTI_Prof_Dump_All()
  input_data = get_input_data()
end do
end program
```

Dumping Profile Data

This discussion provides an example of how to call the C PGO API routines from Fortran.

As part of the instrumented execution phase of PGO, the instrumented program writes profile data to the dynamic information file (.dyn file).

The profile information file is written after the instrumented program returns normally from `PROGRAM()` or calls the standard exit function.

Programs that do not terminate normally, can use the `_PGOPTI_Prof_Dump_All` function. During the instrumentation compilation, using the `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*) option, you can add a call to this function to your program using a strategy similar to the one shown below:

Example

```
interface
  subroutine PGOPTI_Prof_Dump_All()
!DEC$attributes c,alias:'PGOPTI_Prof_Dump_All'::PGOPTI_Prof_Dump_All
  end subroutine
  subroutine PGOPTI_Prof_Reset()
!DEC$attributes c,alias:'PGOPTI_Prof_Reset'::PGOPTI_Prof_Reset
  end subroutine
end interface
call PGOPTI_Prof_Dump_All()
```

CAUTION. You must remove the call or comment it out prior to the feedback compilation with `-prof-use` (Linux and Mac OS X) or `/Qprof-use` (Windows).

Interval Profile Dumping

The `_PGOPTI_Set_Interval_Prof_Dump()` function activates Interval Profile Dumping and sets the approximate frequency at which dumps occur. This function is used in non-terminating applications.

The prototype of the function call is listed below.

Syntax

```
void _PGOPTI_Set_Interval_Prof_Dump(int interval);
```

This function is used in non-terminating applications.

The `interval` parameter specifies the time interval at which profile dumping occurs and is measured in milliseconds. For example, if interval is set to 5000, then a profile dump and reset will occur approximately every 5 seconds. The interval is approximate because the time-check controlling the dump and reset is only performed upon entry to any instrumented function in your application.

Setting the interval to zero or a negative number will disable interval profile dumping, and setting a very small value for the interval may cause the instrumented application to spend nearly all of its time dumping profile information. Be sure to set interval to a large enough value so that the application can perform actual work and substantial profile information is collected.

You can use the profmerge tool to merge the .dyn files.

Recommended usage

Call this function at the start of a non-terminating user application to initiate interval profile dumping. Note that an alternative method of initiating interval profile dumping is by setting the environment variable `INTEL_PROF_DUMP_INTERVAL` to the desired interval value prior to starting the application.

Using interval profile dumping, you should be able to profile a non-terminating application with minimal changes to the application source code.

Resetting the Dynamic Profile Counters

The `_PGOPTI_Prof_Reset()` function resets the dynamic profile counters. The prototype of the function call is listed below.

Syntax
`void _PGOPTI_Prof_Reset(void);`

Recommended usage

Use this function to clear the profile counters prior to collecting profile information on a section of the instrumented application. See the example under Dumping Profile Information.

Dumping and Resetting Profile Information

The `_PGOPTI_Prof_Dump_And_Reset()` function dumps the profile information to a new .dyn file and then resets the dynamic profile counters. Then the execution of the instrumented application continues.

The prototype of the function call is listed below.

Syntax
`void _PGOPTI_Prof_Dump_And_Reset(void);`

This function is used in non-terminating applications and may be called more than once. Each call will dump the profile information to a new .dyn file.

Recommended usage

Periodic calls to this function enables a non-terminating application to generate one or more profile information files (`.dyn` files). These files are merged during the feedback phase (phase 3) of profile-guided optimizations. The direct use of this function enables your application to control precisely when the profile information is generated.

Using High-Level Optimization (HLO) 32

High-Level Optimizations (HLO) Overview

HLO exploits the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Loadpair Optimization
- Predicate Optimization
- Loop Versioning with Runtime Data-Dependence Check (IA-64 architecture only)
- Loop Versioning with Low Trip-Count Check
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Malloc Combining and Memset Combining
- Loop Rerolling
- Memset and Memcpy Recognition
- Statement Sinking for Creating Perfect Loopnests

While the default optimization level, `-O2` (Linux* OS and Mac OS* X) or `/O2` (Windows* OS) option, performs some high-level optimizations (for example, prefetching, complete unrolling, etc.), specifying `-O3` (Linux and Mac OS X) or `/O3` (Windows) provides the best chance for performing loop transformations to optimize memory accesses; the scope of optimizations enabled by these options is different for IA-32 architecture, Intel® 64, and IA-64 architectures.

Applications for the IA-32 and Intel® 64 architectures

In conjunction with the vectorization options, `-ax` and `-x` (Linux and Mac OS X) or `/Qax` and `/Qx` (Windows), the `-O3` (Linux and Mac OS X) or `/O3` (Windows) option causes the compiler to perform more aggressive data dependency analysis than the default `-O2` (Linux and Mac OS X) or `/O2` (Windows).

Compiler prefetching is disabled in favor of the prefetching support available in the processors.

Applications for the IA-32 and IA-64 architectures

The `-O3` (Linux and Mac OS X) or `/O3` (Windows) option enables the `-O2` (Linux and Mac OS X) or `/O2` (Windows) option and adds more aggressive optimizations (like loop transformations); `O3` optimizes for maximum speed, but may not improve performance for some programs.

Applications for the IA-64 architecture

The `-ivdep-parallel` (Linux) or `/Qivdep-parallel` (Windows) option implies there is no loop-carried dependency in the loop where an `IVDEP` directive is specified. (This strategy is useful for sparse matrix applications.)

Tune applications for IA-64 architecture by following these general steps:

1. Compile your program with `-O3` (Linux) or `/O3` (Windows) and `-ipo` (Linux) or `/Qipo` (Windows). Use profile guided optimization whenever possible.
2. Identify hot spots in your code.
3. Generate a high-level optimization report.
4. Check why loops are not software pipelined.
5. Make the changes indicated by the results of the previous steps.
6. Repeat these steps until you achieve the desired performance.

General Application Tuning

In general, you can use the following strategies to tune applications for multiple architectures:

- Use `!DEC$ ivdep` to tell the compiler there is no dependency. You may also need the `-ivdep-parallel` (Linux and Mac OS X) or `/Qivdep-parallel` (Windows) option to indicate there is no loop carried dependency.

- Use `!DEC$ swp` to enable software pipelining (useful for lop-sided control and unknown loop count).
- Use `!DEC$ loop count(n)` when needed.
- If cray pointers are used, use `-safe-cray-ptr` (Linux and Mac OS X) or `/Qsafe-cray-ptr` (Windows) to indicate there is no aliasing.
- Use `!DEC$ distribute point` to split large loops (normally, this is automatically done).
- Check that the prefetch distance is correct. Use `CDEC$ prefetch` to override the distance when it is needed.

Loop Unrolling

The benefits of loop unrolling are as follows:

- Unrolling eliminates branches and some of the code.
- Unrolling enables you to aggressively schedule (or pipeline) the loop to hide latencies if you have enough free registers to keep variables live.
- For processors based on the IA-32 architectures, the processor can correctly predict the exit branch for an inner loop that has 16 or fewer iterations, if that number of iterations is predictable and there are no conditional branches in the loop. Therefore, if the loop body size is not excessive, and the probable number of iterations is known, unroll inner loops for the processors, until they have a maximum of 16 iterations
- A potential limitation is that excessive unrolling, or unrolling of very large loops, can lead to increased code size.

The `-unroll[n]` (Linux* and Mac OS* X) or `/Qunroll:[n]` (Windows*) option controls how the Intel® compiler handles loop unrolling.

Refer to Applying Optimization Strategies for more information.

Linux and Mac OS X	Windows	Description
`-unroll`*n*	`/Qunroll:`*n*	Specifies the maximum number of times you want to unroll a loop. The following examples unrolls a loop four times: `ifort -unroll4 a.f90` (Linux and Mac OS X)

Linux and Mac OS X	Windows	Description
		`ifort /Qunroll:4 a.f90` (Windows) (Linux and Mac OS X) (Windows) **NOTE.** The compilers for IA-64 architecture recognizes only *n* = 0; any other value is ignored. Omitting a value for *n* lets the compiler decide whether to perform unrolling or not. This is the default; the compiler uses default heuristics or defines *n*. Passing 0 as *n* disables loop unrolling; the following examples disables loop unrolling: `ifort -unroll0 a.f90` (Linux and Mac OS X) `ifort /Qunroll:0 a.f90` (Windows) (Linux and Mac OS X) (Windows)

Loop Independence

Loop independence is important since loops that are independent can be parallelized. Independent loops can be parallelized in a number of ways, from the course-grained parallelism of OpenMP*, to fine-grained Instruction Level Parallelism (ILP) of vectorization and software pipelining.

Loops are considered independent when the computation of iteration Y of a loop can be done independently of the computation of iteration X. In other words, if iteration 1 of a loop can be computed and iteration 2 simultaneously could be computed without using any result from iteration 1, then the loops are independent.

Occasionally, you can determine if a loop is independent by comparing results from the output of the loop with results from the same loop written with a decrementing index counter.

For example, the loop shown in example 1 might be independent if the code in example 2 generates the same result.

Example

```
subroutine loop_independent_A (a,b,MAX)
  implicit none
  integer :: j, MAX, a(MAX), b(MAX)
  do j=0, MAX
    a(j) = b(j)
  end do
end subroutine loop_independent_A
subroutine loop_independent_B (a,b,MAX)
  implicit none
  integer :: j, MAX, a(MAX), b(MAX)
  do j=MAX, 0, -1
    a(j) = b(j)
  end do
end subroutine loop_independent_B
```

When loops are dependent, improving loop performance becomes much more difficult. Loops can be dependent in several, general ways.

- Flow Dependency
- Anti Dependency
- Output Dependency
- Reductions

The following sections illustrate the different loop dependencies.

Flow Dependency - Read After Write

Cross-iteration flow dependence is created when variables are written then read in different iterations, as shown in the following example:

Example

```
subroutine flow_dependence (A,MAX)
  implicit none
  integer :: J,MAX
  real :: A(MAX)
  do j=1, MAX
    A(J)=A(J-1)
  end do
end subroutine flow_dependence
```

The above example is equivalent to the following lines for the first few iterations:

Sample Iterations

```
A[1]=A[0];
A[2]=A[1];
```

Recurrence relations feed information forward from one iteration to the next.

Example

```
subroutine time_stepping_loops (a,b,MAX)
  implicit none
  integer :: J,MAX
  real :: a(MAX), b(MAX)
  do j=1, MAX
    a(j) = a(j-1) + b(j)
  end do
end subroutine time_stepping_loops
```

Most recurrences cannot be made fully parallel. Instead, look for a loop further out or further in to parallelize. You might be able to get more performance gains through unrolling.

Anti Dependency - Write After Read

Cross-iteration anti-dependence is created when variables are read then written in different iterations, as shown in the following example:

Example

```
subroutine anti_dependence (A,MAX)
  implicit none
  integer :: J,MAX
  real :: a(MAX), b(MAX)
  do J=1, MAX
    A(J)=A(J+1)
  end do
end subroutine anti_dependence
```

The above example is equivalent to the following lines for the first few iterations:

Sample Iterations

```
A[1]=A[2];
A[2]=A[3];
```

Output Dependency - Write After Write

Cross-iteration output dependence is where variables are written then rewritten in a different iteration. The following example illustrates this type of dependency:

Example

```
subroutine output_dependence (A,B,C,MAX)
  implicit none
  integer :: J,MAX
  real :: a(MAX), b(MAX), c(MAX)
  do J=1, MAX
    A(J)=B(J)
    A(J+1)=C(J)
  end do
end subroutine output_dependence
```

The above example is equivalent to the following lines for the first few iterations:

Sample Iterations

```
A[1]=B[1];
A[2]=C[1];
A[2]=B[2];
A[3]=C[2];
```

Reductions

The Intel® compiler can successfully vectorize or software pipeline (SWP) most loops containing reductions on simple math operators like multiplication (*), addition (+), subtraction (-), and division (/). Reductions collapse array data to scalar data by using associative operations:

Example

```
subroutine reduction (sum,c,MAX)
  implicit none
  integer :: j,MAX
  real :: sum, c(MAX)
  do J=0, MAX
    sum = sum + c(j)
  end do
end subroutine reduction
```

The compiler might occasionally misidentify a reduction and report flow-, anti-, output-dependencies or sometimes loop-carried memory-dependency-edges; in such cases, the compiler will not vectorize or SWP the loop.

Prefetching with Options

The goal of prefetch insertion optimization is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache. The prefetch optimization is enabled or disabled by the `-opt-prefetch` (Linux* and Mac OS* X) or `/Qopt-prefetch` (Windows*) compiler option. This option also allows you to specify the level of software prefetching.

To facilitate compiler optimization:

- Minimize use of global variables and pointers.
- Minimize use of complex control flow.
- Choose data types carefully and avoid type casting.

In addition to the `-opt-prefetch` (Linux and Mac OS X) or `/Qopt-prefetch` (Windows) option, an intrinsic subroutine `mm_prefetch` and compiler directive `prefetch` are also available.

The architecture affects the option behavior. For more information about the differences, see the following topic:

- `-opt-prefetch` compiler option

Optimization Support Features 33

Optimization Support Features Overview

This section describes the language extensions that enable you to optimize your source code directly.

- Loop Support
- Loop Unrolling Support
- Vectorization Support
- Prefetch Support
- Software Pipelining (IA-64 Architecture)

See General Compiler Directives for more information about these directives.

Loop Support

LOOP COUNT Directive

The `LOOP COUNT` directive can affect heuristics used in vectorization, loop-transformations, and software pipelining (IA-64 architecture). The directive can specific the minimum, maximum, or average number of iterations for a `DO` loop. In addition, a list of commonly occurring values can be specified. This behavior might help the compiler generate multiple versions and perform complete unrolling.

The syntax for this directive supports the following syntax variations:

Syntax
!DEC$ LOOP COUNT (*n*)
!DEC$ LOOP COUNT = *n*
or
!DEC$ LOOP COUNT (*n1*[,*n2*]...)
!DEC$ LOOP COUNT = *n1*[,*n2*]...
or
!DEC$ LOOP COUNT MAX(*n*), AVG(*n*)
!DEC$ LOOP COUNT MAX=*n*, MIN=*n*, AVG=*n*

The syntax variations support the following arguments:

Argument	Description
(*n*) or =*n*	Non-negative integer value. The compiler will attempt to iterate the next loop the number of times specified in *n*; however, the number of iterations is not guaranteed.
(*n1*[,*n2*]...) or =*n1*[,*n2*]...	Non-negative integer values. The compiler will attempt to iterate the next loop the number of time specified by *n1* or *n2*, or some other unspecified number of times. This behavior allows the compiler some flexibility in attempting to unroll the loop. The number of iterations is not guaranteed.
min(*n*), max(*n*), >avg(*n*) or min=*n*, max=*n*, avg=*n*	Non-negative integer values. Specify one or more in any order without duplication. The compiler insures the next loop iterates for the specified maximum, minimum, or average number (*n1*) of times. The specified number of iterations is guaranteed for min and max.

You can specify more than one directive for a single loop; however, do not duplicate the directive.

The following example illustrates how to use the directive to iterate through the loop and enable software pipelining on IA-64 architectures.

Using Loop Count (n)

```
subroutine loop_count(a, b, N)
integer :: i, N, b(N), c(N)
!DEC$ LOOP COUNT (1000)
 do i = 1, 1000
   b(i) = a(i) + 1
 enddo
end subroutine loop_count
```

The following example illustrates how to use the directive to iterate through the loop a minimum of three, a maximum of ten, and average of five times.

Using Loop Count min, max, avg

```
!DEC$ LOOP COUNT MIN(3), MAX(10), AVG(5)
DO i = 1, 15
  PRINT i
END DO
```

DISTRIBUTE POINT Directive

The `DISTRIBUTE POINT` directive instructs the compiler to prefer loop distribution at the location indicated. The syntax for this directive is shown below:

Syntax

```
!DEC$ DISTRIBUTE POINT
```

Loop distribution can cause large loops to be distributed into smaller ones. This strategy can enable software pipelining for the new, smaller loops (IA-64 architecture).

- If the directive is placed inside a loop, distribution is performed after the directive and any loop-carried dependency is ignored.

- If the directive is placed before a loop, the compiler determines where to distribute the loops and observes data dependency. If they are placed inside the loop, the compiler supports multiple instances of the directive.

Using distribute point

```
subroutine dist1(a, b, c, d, N)
  integer :: i, N, a(N), b(N), c(N), d(N)
 !DEC$ DISTRIBUTE POINT
  do i = 1, N
    b(i) = a(i) + 1
    c(i) = a(i) + b(i)
 ! Compiler will decide where to distribute.
 ! Data dependency is observed.
    d(i) = c(i) + 1
  enddo
end subroutine dist1
subroutine dist2(a, b, c, d, N)
  integer :: i, N, a(N), b(N), c(N), d(N)
  do i = 1, N
    b(i) = a(i) + 1
    !DEC$

 DISTRIBUTE POINT
 ! Distribution will start here, ignoring all
 ! loop-carried dependency.
    c(i) = a(i) + b(i)
    d(i) = c(i) + 1
  enddo
end subroutine dist2
```

Loop Unrolling Support

The UNROLL[*n*] directive tells the compiler how many times to unroll a counted loop. The general syntax for this directive is shown below:

Syntax

```
!DEC$ UNROLL(n)
```

where *n* is an integer constant from 0 through 255.

The UNROLL directive must precede the DO statement for each DO loop it affects. If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted or if it is outside the allowed range, the optimizer assigns the number of times to unroll the loop.

This directive is supported only when option -O3 (Linux* OS and Mac OS* X) or /O3 (Windows* OS) is used. The UNROLL directive overrides any setting of loop unrolling from the command line.

Currently, the directive can be applied only for the innermost loop nest. If applied to the outer loop nests, it is ignored. The compiler generates correct code by comparing *n* and the loop count.

Example

```
subroutine unroll(a, b, c, d)
  integer :: i, b(100), c(100), d(100)
  !DEC$ UNROLL(4)
  do i = 1, 100
    b(i) = a(i) + 1
    d(i) = c(i) + 1
  enddo
end subroutine unroll
```

Vectorization Support

IVDEP Directive

The `IVDEP` directive instructs the compiler to ignore assumed vector dependences. To ensure correct code, the compiler treats an assumed dependence as a proven dependence, which prevents vectorization. This directive overrides that decision. Use `IVDEP` only when you know that the assumed loop dependences are safe to ignore.

For example, if the expression `j >= 0` is always true in the code fragment bellow, the `IVDEP` directive can communicate this information to the compiler. This directive informs the compiler that the conservatively assumed loop-carried flow dependences for values `j < 0` can be safely ignored:

Example

```
!DEC$ IVDEP
  do i = 1, 100
     a(i) = a(i+j)
  enddo
```

NOTE. The proven dependences that prevent vectorization are not ignored, only assumed dependences are ignored.

The usage of the directive differs depending on the loop form, see examples below.

Example: Loop 1

```
do i
     = a(*) + 1
    a(*) =
 enddo
```

Example: Loop 2

```
do i
    a(*) =
         = a(*) + 1
 enddo
```

For loops of the form 1, use old values of *a*, and assume that there is no loop-carried flow dependencies from `DEF` to `USE`.

For loops of the form 2, use new values of *a*, and assume that there is no loop-carried anti-dependencies from `USE` to `DEF`.

In both cases, it is valid to distribute the loop, and there is no loop-carried output dependency.

Example 1

```
!DEC$ IVDEP
do j=1,n
  a(j)= a(j+m) + 1
enddo
```

Example 2

```
!DEC$ IVDEP
do j=1,n
  a(j) = b(j) + 1
  b(j) = a(j+m) + 1
enddo
```

Example 1 ignores the possible backward dependencies and enables the loop to get software pipelined.

Example 2 shows possible forward and backward dependencies involving array *a* in this loop and creating a dependency cycle. With `IVDEP`, the backward dependencies are ignored.

IVDEP has options: `IVDEP:LOOP` and `IVDEP:BACK`. The `IVDEP:LOOP` option implies no loop-carried dependencies. The `IVDEP:BACK` option implies no backward dependencies.

The IVDEP directive is also used for IA-64 architecture based applications.

Overriding the Efficiency Heuristics in the Vectorizer

In addition to IVDEP directive, there are VECTOR directives that can be used to override the efficiency heuristics of the vectorizer:

- `VECTOR ALWAYS`
- `NOVECTOR`
- `VECTOR ALIGNED`
- `VECTOR UNALIGNED`

- VECTOR NONTEMPORAL

The VECTOR directives control the vectorization of the subsequent loop in the program, but the compiler does not apply them to nested loops. Each nested loop needs its own directive preceding it. You must place the vector directive before the loop control statement.

VECTOR ALWAYS and NOVECTOR Directives

The VECTOR ALWAYS directive overrides the efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized, that is: use IVDEP to ignore assumed dependences.

The VECTOR ALWAYS directive can be used to override the default behavior of the compiler in the following situation. Vectorization of non-unit stride references usually does not exhibit any speedup, so the compiler defaults to not vectorizing loops that have a large number of non-unit stride references (compared to the number of unit stride references). The following loop has two references with stride 2.

Vectorization would be disabled by default, but the directive overrides this behavior.

Example

```
!DEC$ VECTOR ALWAYS
do i = 1, 100, 2
  a(i) = b(i)
enddo
```

If, on the other hand, avoiding vectorization of a loop is desirable (if vectorization results in a performance regression rather than improvement), the NOVECTOR directive can be used in the source text to disable vectorization of a loop. For instance, the compiler vectorizes the following example loop by default. If this behavior is not appropriate, the NOVECTOR directive can be used, as shown below.

Example

```
!DEC$ NOVECTOR
do i = 1, 100
  a(i) = b(i) + c(i)
enddo
```

VECTOR ALIGNED/UNALIGNED Directives

Like VECTOR ALWAYS, these directives also override the efficiency heuristics. The difference is that the qualifiers UNALIGNED and ALIGNED instruct the compiler to use, respectively, unaligned and aligned data movement instructions for all array references. This disables all the advanced alignment optimizations of the compiler, such as determining alignment properties from the program context or using dynamic loop peeling to make references aligned.

NOTE. The directives VECTOR [ALWAYS|UNALIGNED|ALIGNED] should be used with care. Overriding the efficiency heuristics of the compiler should only be done if the programmer is absolutely sure the vectorization will improve performance. Furthermore, instructing the compiler to implement all array references with aligned data movement instructions will cause a run-time exception in case some of the access patterns are actually unaligned.

The VECTOR NONTEMPORAL Directive

The VECTOR NONTEMPORAL directive results in streaming stores on the systems based on IA-32 and Intel® 64 architectures. A floating-point type loop together with the generated assembly are shown in the example below. For large *n*, significant performance improvements result on a Pentium 4 system over a non-streaming implementation.

The following example shows the VECTOR NONTEMPORAL directive that directs the compiler to use streaming store on the array *a* but not for the array *b*:

Example

```
subroutine set(a,b,n)
integer i,n
real a(n), b(n)
!DEC$ VECTOR NONTEMPORAL (a)
!DEC$ VECTOR ALIGNED
do i = 1, n
  a(i) = 1
  b(i) = 1
enddo
end
program setit
parameter(n=1024*1204)
real a(n), b(n)
integer i
do i = 1, n
  a(i) = 0
enddo
call set(a,b,n)
do i = 1, n
  if (a(i)+b(i).ne.2) then
    print *, 'failed nontemp.f', a(i), i
    stop
  endif
enddo
print *, 'passed nontemp.f'
```

Example
`end`

Prefetching Support

Data prefetching refers to loading data from a relatively slow memory into a relatively fast cache before the data is needed by the application. Data prefetch behavior depends on the architecture:

- IA-64 architecture: The Intel® compiler generally issues prefetch instructions when you specify `-O1`, `-O2`, and `-O3` (Linux*) or `/O1`, `/O2`, and `/O3` (Windows*).
- IA-32 and Intel® 64 architectures: The processor identifies simple, regular data access patterns and performs a hardware prefetch. The compiler will only issue prefetch instructions for more complicated data access patterns where a hardware prefetch is not expected.

Issuing prefetches improves performance in most cases; however, there are cases where issuing prefetch instructions might slow application performance. Experiment with prefetching; it can be helpful to turn prefetching on or off with a compiler option while leaving all other optimizations unaffected to isolate a suspected prefetch performance issue. See Prefetching with Options for information on using compiler options for prefetching data.

There are two primary methods of issuing prefetch instructions. One is by using compiler directives and the other is by using compiler intrinsics.

PREFETCH and NOPREFETCH Directives

The `PREFETCH` and `NOPREFETCH` directives are supported by Itanium® processors only. These directives assert that the data prefetches be generated or not generated for some memory references. This affects the heuristics used in the compiler.

If loop includes expression `A(j)`, placing `PREFETCH A` in front of the loop, instructs the compiler to insert prefetches for `A(j + d)` within the loop. `d` is the number of iterations ahead to prefetch the data and is determined by the compiler. This directive is supported with optimization levels of `-O1` (Linux*) or `/O1` (Windows*) or higher. Remember that `-O2` or `/O2` is the default optimization level.

Example

```
!DEC$ NOPREFETCH c
!DEC$ PREFETCH a
  do i = 1, m
    b(i) = a(c(i)) + 1
  enddo
```

The following example is for IA-64 architecture only:

Example

```
do j=1,lastrow-firstrow+1
i = rowstr(j)
iresidue = mod( rowstr(j+1)-i, 8 )
sum = 0.d0
!DEC$ NOPREFETCH a,p,colidx
do k=i,i+iresidue-1
  sum = sum +  a(k)*p(colidx(k))
enddo
!DEC$ NOPREFETCH colidx
!DEC$ PREFETCH a:1:40
!DEC$ PREFETCH p:1:20
do k=i+iresidue, rowstr(j+1)-8, 8
  sum = sum + a(k  )*p(colidx(k  ))
  &      + a(k+1)*p(colidx(k+1)) + a(k+2)*p(colidx(k+2))
  &      + a(k+3)*p(colidx(k+3)) + a(k+4)*p(colidx(k+4))
  &      + a(k+5)*p(colidx(k+5)) + a(k+6)*p(colidx(k+6))
  &      + a(k+7)*p(colidx(k+7))
enddo
q(j) = sum
enddo
```

Intrinsics

Before inserting compiler intrinsics, experiment with all other supported compiler options and directives. Compiler intrinsics are less portable and less flexible than either a compiler option or compiler directives.

Directives enable compiler optimizations while intrinsics perform optimizations. As a result, programs with directives are more portable, because the compiler can adapt to different processors, while the programs with intrinsics may have to be rewritten/ported for different processors. This is because intrinsics are closer to assembly programming.

The compiler supports an intrinsic subroutine `mm_prefetch`. In contrast the way the `prefetch` directive enables a data prefetch from memory, the subroutine `mm_prefetch` prefetches data from the specified address on one memory cache line. The `mm_prefetch` subroutine is described in the *Intel® Fortran Language Reference*.

Software Pipelining Support (IA-64 Architecture)

The `SWP` directive indicates preference for loops to be software pipelined. The directive does not help data dependency, but overrides heuristics based on profile counts or unequal control flow.

The syntax for this directive is shown below:

Syntax
`!DEC$ SWP`

The Software Pipelining optimization triggered by the `SWP` directive applies instruction scheduling to certain innermost loops, allowing instructions within a loop to be split into different stages, allowing increased instruction level parallelism.

This strategy can reduce the impact of long-latency operations, resulting in faster loop execution. Loops chosen for software pipelining are always innermost loops that do not contain procedure calls that are not inlined. Because the optimizer no longer considers fully unrolled loops as innermost loops, fully unrolling loops can allow an additional loop to become the innermost loop (see loop unrolling options).

You can view an optimization report to see whether software pipelining was applied (see Optimizer Report Generation).

The following example demonstrates on way of using the directive to instruct the compiler to attempt software pipelining.

Example: Using SWP

```
subroutine swp(a, b)
  integer :: i, a(100), b(100)
  !DEC$ SWP
  do i = 1, m
    if (a(i) .eq. 0)

 then
       b(i) = a(i) + 1
    else
       b(i) = a(i)/c(i)
    endif
  enddo
end subroutine swp
```

About Register Allocation

The Intel® Compiler for IA-32 and Intel® 64 architectures contains an advanced, region-based register allocator. Register allocation can be influenced using the `-opt-ra-region-strategy` (Linux* and Mac OS* X) and `/Qopt-ra-region-strategy` (Windows*) option.

The register allocation high-level strategy when compiling a routine is to partition the routine into regions, assign variables to registers or memory within each region, and resolve discrepancies at region boundaries. The overall quality of the allocation depends heavily on the region partitioning.

By default, the Intel Compiler selects the best region partitioning strategy, but the `-opt-ra-region-strategy` (Linux* and Mac OS X) and `/Qopt-ra-region-strategy` (Windows) option allows you to experiment with the other available allocation strategies, which might result in better performance in some cases. The option provides several different arguments that allow you to specify the following allocation strategies:

- routine = a region for each routine

- trace = a region for each trace
- loop = a region for each loop
- block = a region for each block
- default = the compiler selects best allocation strategy

See the `/Qopt-ra-region-strategy` (Windows) `-opt-ra-region-strategy` (Linux and Mac OS X) compiler option for additional information.

The option can affect compile time. Register allocation is a relatively costly operation, and the time spent in register allocation tends to grow as the number of regions increases. Expect relative compile time to increase in the order listed, from shortest to longest:

1. routine-based regions (shortest)
2. loop-based regions
3. trace-based regions
4. block-based regions (longest)

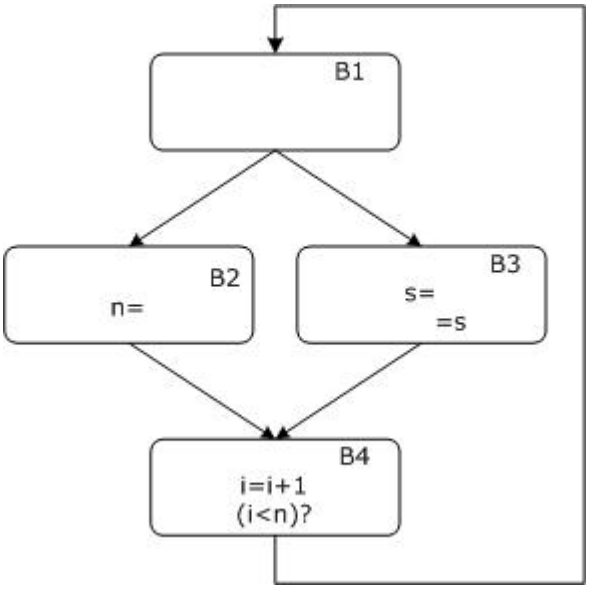
Trace-based regions tend to work very well when profile guided optimizations are enabled. The allocator is able to construct traces that accurately reflect the hot paths through the routine.

In the absence of profile information, loop-based regions tend to work well because the execution profile of a program tends to match its loop structure. In programs where the execution profile does not match the loop structure, routine- or block-based regions can produce better allocations.

Block-based regions provide maximum flexibility to the allocator and in many cases can produce the best allocation; however, the allocator is sometimes over-aggressive with block-based regions about allocating variables to registers; the behavior can lead to poor allocations in the IA-32 and Intel® 64 architectures where registers can be scarce resources.

Register Allocation Example Scenarios

Consider the following example, which illustrates a control flow that results from a simple if-then-else statement within a loop.



There are 3 variables in this loop: *i*, *s*, and *n*. For this example, assume there are only two registers available to hold these three variables; one, or more, variable will need to be stored in memory for at least part of the loop.

The best choice depends on which path through the loop is more frequently executed. For example, if B1, B2, B4 is the hot path, keeping variables *i* and *n* in registers along that path and saving and restoring one of them in B3 to free up a register for *s* is the best strategy. That scenario avoids all memory accesses on the hot path. If B1, B3, B4 is the hot path, the best strategy is to keep variables *i* and *s* in registers and to store n in memory, since there are no assignments to *n* along the path. This strategy results in a single memory read on the hot path. If both paths are executed with equal frequency, the best strategy is to save and restore either *i* or *n* around B3 just like in the B1, B2, B4 case. That case avoids all memory accesses on one path and results in a single memory write and a single memory read on the other path.

The compiler generates two significantly different allocations for this example depending on the region strategy; the preferred result depends on the runtime behavior of the program, which may not be known at compile time.

With a routine- or a loop-based strategy, all four blocks will be allocated together. The compiler picks a variable to store in memory based on expected costs. In this example, the allocator will probably select variable *n*, resulting in a memory write in B2 and a memory read in B3.

With a trace-based strategy, the compiler uses estimates of execution frequency to select the most frequently executed path through the loop. When profile guided optimizations are enabled the estimates are based on the concrete information about the runtime behavior of the instrumented program. If the PGO information accurately reflects typical application behavior, the compiler produces highly accurate traces. In other cases, the traces are not necessarily an accurate reflection of the hot paths through the code.

Suppose in this example that the compiler selects B1, B2, B4 path as the hot trace. The compiler will assign these three blocks to one region, and B3 will be in a separate region. There are only two variables in the larger region, so both may be kept in registers. In the region containing just B3 either `i` or `n` are stored in memory, and the compiler makes an arbitrary choice between the two variables. In a block-based strategy, each block is a region. In the B1, B2, B4 path there are sufficient registers to hold the two variables: `i` and `n`. The region containing B3 is treated just like the trace-based case; either `i` or `n` will be stored in memory.

Programming Guidelines 34

Coding Guidelines for Intel® Architectures

This topic provides general guidelines for coding practices and techniques for using:

- IA-32 and Intel® 64 architectures supporting MMX™ technology and Intel® Streaming SIMD Extensions Streaming SIMD Extensions (SSE), Streaming SIMD Extensions 2 (SSE2), Streaming SIMD Extensions 3 (SSE3), and Streaming SIMD Extensions 4 (SSE4)
- IA-64 architecture

This section describes practices, tools, coding rules and recommendations associated with the architecture features that can improve the performance for processors based on IA-32, Intel® 64, and IA-64 architectures.

NOTE. If a guideline refers to a particular architecture only, this architecture is explicitly named. The default is for IA-32 architectures.

Performance of compiler-generated code may vary from one compiler to another. Intel® Fortran Compiler generates code that is optimized for Intel architectures. You can significantly improve performance by using various compiler optimization options. In addition, you can help the compiler to optimize your Fortran program by following the guidelines described in this section.

To achieve optimum processor performance in your Fortran application, do the following:

- avoiding memory access stalls
- ensuring good floating-point performance
- ensuring good SIMD integer performance
- using vectorization

The following sections summarize and describe coding practices, rules and recommendations associated with the features that will contribute to optimizing the performance on Intel architecture-based processors.

Memory Access

The Intel compiler lays out arrays in column-major order. For example, in a two-dimensional array, elements `A(22,34)` and `A(23,34)` are contiguous in memory. For best performance, code arrays so that inner loops access them in a contiguous manner.

Consider the following examples. The code in example 1 will likely have higher performance than the code in example 2.

Example 1

```
subroutine contiguous(a, b, N)
  integer :: i, j, N, a(N,N), b(N,N)
  do j = 1, N
    do i = 1, N
      b(i, j) = a(i, j) + 1
    end do
  end do
end subroutine contiguous
```

The code above illustrates access to arrays `A` and `B` in the inner loop `I` in a contiguous manner which results in good performance; however, the following example illustrates access to arrays `A` and `B` in inner loop `J` in a non-contiguous manner which results in poor performance.

Example 2

```
subroutine non_contiguous(a, b, N)
  integer :: i, j, N, a(N,N), b(N,N)
  do i = 1, N
    do j = 1, N
      b(i, j) = a(i, j) + 1
    end do
  end do
end subroutine non_contiguous
```

The compiler can transform the code so that inner loops access memory in a contiguous manner. To do that, you need to use advanced optimization options, such as `-O3` (Linux* OS) or `/O3` (Windows* OS) for IA-32, Intel® 64, and IA-64 architectures, and `-O3` (Linux) or `/O3` (Windows) and `-ax` (Linux) or `/Qax` (Windows) for IA-32 architecture only.

Memory Layout

Alignment is an increasingly important factor in ensuring good performance. Aligned memory accesses are faster than unaligned accesses. If you use the interprocedural optimization on multiple files, the `-ipo` (Linux) or `/Qipo` (Windows) option, the compiler analyzes the code and decides whether it is beneficial to pad arrays so that they start from an aligned boundary. Multiple arrays specified in a single common block can impose extra constraints on the compiler.

For example, consider the following `COMMON` statement:

Example 3

```
COMMON /AREA1/ A(200), X, B(200)
```

If the compiler added padding to align `A(1)` at a 16-byte aligned address, the element `B(1)` would not be at a 16-byte aligned address. So it is better to split `AREA1` as follows.

Example 4

```
COMMON /AREA1/ A(200)
COMMON /AREA2/ X
COMMON /AREA3/ B(200)
```

The above code provides the compiler maximum flexibility in determining the padding required for both `A` and `B`.

Setting Data Type and Alignment

Alignment of data affects these kinds of variables:

- Those that are dynamically allocated. (Dynamically allocated data allocated with `ALLOCATE` is 8-byte aligned.)
- Those that are members of a data structure
- Those that are global or local variables

- Those that are parameters passed on the stack

For best performance, align data as follows:

- Align 8-bit data at any address.
- Align 16-bit data to be contained within an aligned four byte word.
- Align 32-bit data so that its base address is a multiple of four.
- Align 64-bit data so that its base address is a multiple of eight.
- Align 128-bit data so that its base address is a multiple of sixteen (8-byte boundaries).

Causes of Unaligned Data and Ensuring Natural Alignment

For optimal performance, make sure your data is aligned naturally. A natural boundary is a memory address that is a multiple of the data item's size. For example, a `REAL (KIND=8)` data item aligned on natural boundaries has an address that is a multiple of 8. An array is aligned on natural boundaries if all of its elements are so aligned.

All data items whose starting address is on a natural boundary are naturally aligned. Data not aligned on a natural boundary is called unaligned data.

Although the Intel® compiler naturally aligns individual data items when it can, certain Fortran statements can cause data items to become unaligned.

You can use the align command-option to ensure naturally aligned data, but you should check and consider reordering data declarations of data items within common blocks, derived-type structures, and record structures as follows:

- Carefully specify the order and sizes of data declarations to ensure naturally aligned data.
- Start with the largest size numeric items first, followed by smaller size numeric items, and then non-numeric (character) data.

The `!DEC$ ATTRIBUTES ALIGN` directive specifies the byte alignment for a variable.

Common blocks (`COMMON` statement), derived-type data, and record structures (`RECORD` statement) usually contain multiple items within the context of the larger structure.

The following statements can cause unaligned data:

Statement	Options	Description
Common blocks (COMMON statement)	`commons` or `dcommons`	The order of variables in the `COMMON` statement determines their storage

Statement	Options	Description
		order. Unless you are sure that the data items in the common block will be naturally aligned, specify either `-align commons` or `-align dcommons` (Linux*) or `/align:commons` or `/align:dcommons` (Windows*), depending on the largest data size used.
Derived-type (user-defined) data	`records` or `sequence`	Derived-type data items are declared after a `TYPE` statement. If your data includes derived-type data structures, you should use the `-align records` (Linux) or `/align:records` (Windows) option, unless you are sure that the data items in the derived-type structures will be naturally aligned. If you omit the sequence statement, the `-align records` (Linux) or `/align:records` (Windows) option (default) ensures all data items are naturally aligned. If you specify the `SEQUENCE` statement, the `-align records` (Linux) or `/align:records` (Windows) option is prevented from adding necessary padding to

Statement	Options	Description
		avoid unaligned data (data items are packed) unless you specify `SEQUENCE`. When you use `SEQUENCE`, you should specify data declaration order so that all data items are naturally aligned.
Record structures (RECORD and STRUCTURE statements)	`record` or `structure`	Intel Fortran record structures usually contain multiple data items. The order of variables in the `STRUCTURE` statement determines their storage order. The `RECORD` statement names the record structure. Record structures are an Intel Fortran language extension. If your data includes record structures, you should use the `-align records` (Linux) or `/align:records` (Windows) option, unless you are sure that the data items in the record structures will be naturally aligned.
EQUIVALENCE statements		`EQUIVALENCE` statements can force unaligned data or cause data to span natural boundaries. For more information, see the *Intel® Fortran Language Reference*.

To avoid unaligned data in a common block, derived-type data, or record structure (extension), use one or both of the following:

- For new programs or for programs where the source code declarations can be modified easily, plan the order of data declarations with care. For example, you should order variables in a COMMON statement such that numeric data is arranged from largest to smallest, followed by any character data (see the data declaration rules in Ordering Data Declarations to Avoid Unaligned Data below.
- For existing programs where source code changes are not easily done or for array elements containing derived-type or record structures, you can use command line options to request that the compiler align numeric data by adding padding spaces where needed.

Other possible causes of unaligned data include unaligned actual arguments and arrays that contain a derived-type structure or Intel Fortran record structure as detailed below.

- When actual arguments from outside the program unit are not naturally aligned, unaligned data access occurs. Intel Fortran assumes all passed arguments are naturally aligned and has no information at compile time about data that will be introduced by actual arguments during program execution.
- For arrays where each array element contains a derived-type structure or Intel Fortran record structure, the size of the array elements may cause some elements (but not the first) to start on an unaligned boundary.
- Even if the data items are naturally aligned within a derived-type structure without the SEQUENCE statement or a record structure, the size of an array element might require use of the `-align records` (Linux) or `/align:records` (Windows) option to supply needed padding to avoid some array elements being unaligned.
- If you specify `-align norecords` (Linux) or `/align:norecords` (Windows) or specify `-vms` (Linux) or `/Qvms` (Windows) without RECORDS no padding bytes are added between array elements. If array elements each contain a derived-type structure with the SEQUENCE statement, array elements are packed without padding bytes regardless of the Fortran command options specified. In this case, some elements will be unaligned.
- When the `-align records` (Linux) or `/align:records` (Windows)option is in effect, the number of padding bytes added by the compiler for each array element is dependent on the size of the largest data item within the structure. The compiler determines the size of the array elements as an exact multiple of the largest data item in the derived-type structure without the SEQUENCE statement or a record structure. The compiler then adds the appropriate number of padding bytes. For instance, if a structure contains an 8-byte floating-point number followed by a 3-byte character variable, each element contains five bytes of padding (16 is an exact multiple of 8). However, if the structure contains one 4-byte floating-point number, one 4-byte integer, followed by a 3-byte character variable, each element would contain one byte of padding (12 is an exact multiple of 4).

Checking for Inefficient Unaligned Data

During compilation, the Intel compiler naturally aligns as much data as possible. Exceptions that can result in unaligned data are described above.

Because unaligned data can slow run-time performance, it is worthwhile to:

- Double-check data declarations within common block, derived-type data, or record structures to ensure all data items are naturally aligned (see the data declaration rules in the subsection below). Using modules to contain data declarations can ensure consistent alignment and use of such data.
- Avoid the `EQUIVALENCE` statement or use it in a manner that cannot cause unaligned data or data spanning natural boundaries.
- Ensure that passed arguments from outside the program unit are naturally aligned.
- Check that the size of array elements containing at least one derived-type data or record structure (extension) cause array elements to start on aligned boundaries (see the previous subsection).
- There are two ways unaligned data might be reported:
  - During compilation, warning messages are issued for any data items that are known to be unaligned (unless you specify the `-warn noalignments` (or `-warn none`) (Linux) or `/warn:noalignments` (or `/warn:none`) (Windows) option that suppresses all warnings).
  - During program execution, warning messages are issued for any data that is detected as unaligned. The message includes the address of the unaligned access.

Consider the following run-time message:

Example

```
Unaligned access pid=24821 <a.out> va=140000154, pc=3ff80805d60,
ra=1200017bc
```

This message shows that:

- The statement accessing the unaligned data (program counter) is located at 3ff80805d60
- The unaligned data is located at address 140000154

Ordering Data Declarations to Avoid Unaligned Data

For new programs or when the source declarations of an existing program can be easily modified, plan the order of your data declarations carefully to ensure the data items in a common block, derived-type data, record structure, or data items made equivalent by an `EQUIVALENCE` statement will be naturally aligned.

Use the following rules to prevent unaligned data:

- Always define the largest size numeric data items first.
- If your data includes a mixture of character and numeric data, place the numeric data first.
- Add small data items of the correct size (or padding) before otherwise unaligned data to ensure natural alignment for the data that follows.

When declaring data, consider using explicit length declarations, such as specifying a `KIND` parameter. For example, specify `INTEGER(KIND=4)` (or `INTEGER(4)`) rather than `INTEGER`. If you do use a default size (such as `INTEGER`, `LOGICAL`, `COMPLEX`, and REAL), be aware that the following compiler options can change the size of an individual field's data declaration size and thus can alter the data alignment of a carefully planned order of data declarations:

Operating System	Compiler Option
Windows*	`/4I` or `/4R`
Linux* and Mac OS* X	`-integer_size` or `-real_size`

Using the suggested data declaration guidelines minimizes the need to use the `-align keyword` (Linux) or `/align:keyword` (Windows) options to add padding bytes to ensure naturally aligned data. In cases where the `-align keyword` (Linux) or `/align:keyword` (Windows) options are still needed, using the suggested data declaration guidelines can minimize the number of padding bytes added by the compiler.

Arranging Data Items in Common Blocks

The order of data items in a COMMON statement determines the order in which the data items are stored. Consider the following declaration of a common block named X:

Example

```
logical (kind=2) flag
integer          iarry_i(3)
character(len=5) name_ch
common /x/ flag, iarry_i(3), name_ch
```

As shown in Figure 1-1, if you omit the appropriate Fortran command options, the common block will contain unaligned data items beginning at the first array element of IARRY_I.

Figure 22: Figure 1-1 Common Block with Unaligned Data

As shown in Figure 1-2, if you compile the program units that use the common block with the -align commons (Linux) or /align:commons (Windows) option, data items will be naturally aligned.

Figure 23: Figure 1-2 Common Block with Naturally Aligned Data

Because the common block X contains data items whose size is 32 bits or smaller, specify the -align commons (Linux) or /align:commons (Windows) option. If the common block contains data items whose size might be larger than 32 bits (such as REAL (KIND=8) data), use the -align dcommons (Linux) or /align:dcommons (Windows) option.

If you can easily modify the source files that use the common block data, define the numeric variables in the COMMON statement in descending order of size and place the character variable last. This provides more portability, ensures natural alignment without padding, and does not require the Fortran command options -align commons (Linux) or -align dcommons (Linux) or /align commons (Windows) or /align:dcommons (Windows):

Example

```
LOGICAL (KIND=2) FLAG
INTEGER          IARRY_I(3)
CHARACTER(LEN=5) NAME_CH
COMMON /X/ IARRY_I(3), FLAG, NAME_CH
```

As shown in Figure 1-3, if you arrange the order of variables from largest to smallest size and place character data last, the data items will be naturally aligned.

Figure 24: Figure 1-3 Common Block with Naturally Aligned Reordered Data

When modifying or creating all source files that use common block data, consider placing the common block data declarations in a module so the declarations are consistent. If the common block is not needed for compatibility (such as file storage or Fortran 77 use), you can place the data declarations in a module without using a COMMON block.

Arranging Data Items in Derived-Type Data

Like common blocks, derived-type data may contain multiple data items (members).

Data item components within derived-type data will be naturally aligned on up to 64-bit boundaries, with certain exceptions related to the use of the SEQUENCE statement and Fortran options.

Intel Fortran stores a derived data type as a linear sequence of values, as follows:

- If you specify the SEQUENCE statement, the first data item is in the first storage location and the last data item is in the last storage location. The data items appear in the order in which they are declared. The Fortran options have no effect on unaligned data, so data

declarations must be carefully specified to naturally align data. The `-align sequence` (Linux) or `/align:sequence` (Windows) option specifically aligns data items in a `SEQUENCE` derived-type on natural boundaries.

- If you omit the `SEQUENCE` statement, the Intel Fortran adds the padding bytes needed to naturally align data item components, unless you specify the `-align norecords` (Linux) or `/align:norecords` (Windows) option.

Consider the following declaration of array `CATALOG_SPRING` of derived-type `PART_DT`:

Example

```
MODULE DATA_DEFS
  TYPE PART_DT
    INTEGER           IDENTIFIER
    REAL              WEIGHT
    CHARACTER(LEN=15) DESCRIPTION
  END TYPE PART_DT
  TYPE (PART_DT) CATALOG_SPRING(30)
...
END MODULE DATA_DEFS
```

As shown in Figure 1-4, the largest numeric data items are defined first and the character data type is defined last. There are no padding characters between data items and all items are naturally aligned. The trailing padding byte is needed because `CATALOG_SPRING` is an array; it is inserted by the compiler when the `-align records` (Linux) or `/align:records` (Windows) option is in effect.

Figure 25: Figure 1-4 Derived-Type Naturally Aligned Data (in CATALOG_SPRING : (,))

Arranging Data Items in Intel Fortran Record Structures

Intel Fortran supports record structures provided by Intel Fortran. Intel Fortran record structures use the RECORD statement and optionally the `STRUCTURE` statement, which are extensions to the Fortran 77 and Fortran standards. The order of data items in a `STRUCTURE` statement determines the order in which the data items are stored.

Intel Fortran stores a record in memory as a linear sequence of values, with the record's first element in the first storage location and its last element in the last storage location. Unless you specify `-align norecords` (Linux) or `/align:norecords` (Windows) padding bytes are added if needed to ensure data fields are naturally aligned.

The following example contains a structure declaration, a RECORD statement, and diagrams of the resulting records as they are stored in memory:

Example

```
STRUCTURE /STRA/
  CHARACTER*1 CHR
  INTEGER*4 INT
END STRUCTURE
...
RECORD /STRA/ REC
```

Figure 1-5 shows the memory diagram of record `REC` for naturally aligned records.

Figure 26: Figure 1-5 Memory Diagram of `REC` for Naturally Aligned Records

Using Arrays Efficiently

This topic discusses how to efficiently access arrays and pass array arguments.

Accessing Arrays Efficiently

Many of the array access efficiency techniques described in this section are applied automatically by the Intel Fortran loop transformation optimizations. Several aspects of array use can improve run-time performance; the following sections discuss the most important aspects.

Perform the fewest operations necessary

The fastest array access occurs when contiguous access to the whole array or most of an array occurs. Perform one or a few array operations that access all of the array or major parts of an array instead of numerous operations on scattered array elements. Rather than use explicit loops for array access, use elemental array operations, such as the following line that increments all elements of array variable `A`:

Example

```
A = A + 1
```

When reading or writing an array, use the array name and not a DO loop or an implied DO-loop that specifies each element number. Fortran 95/90 array syntax allows you to reference a whole array by using its name in an expression.

For example:

Example

```
REAL ::  A(100,100)
A = 0.0
A = A + 1           ! Increment all elements
                    ! of A by 1
...
WRITE (8) A         ! Fast whole array use
```

Similarly, you can use derived-type array structure components, such as:

Example

```
TYPE X
  INTEGER A(5)
END TYPE X
...
TYPE (X) Z
WRITE (8)Z%A        ! Fast array structure
                    ! component use
```

Access arrays using the proper array syntax

Make sure multidimensional arrays are referenced using proper array syntax and are traversed in the natural ascending storage order, which is column-major order for Fortran. With column-major order, the leftmost subscript varies most rapidly with a stride of one. Whole array access uses column-major order.

Avoid row-major order, as is done by C, where the rightmost subscript varies most rapidly. For example, consider the nested `DO` loops that access a two-dimension array with the `J` loop as the innermost loop:

Example

```
INTEGER  X(3,5), Y(3,5), I, J
Y = 0
DO I=1,3                  ! I outer loop varies slowest
  DO J=1,5                ! J inner loop varies fastest
    X (I,J) = Y(I,J) + 1
```

Example

```
  ! Inefficient row-major storage order
  END DO                   ! (rightmost subscript varies fastest)
END DO
...
END PROGRAM
```

Since `J` varies the fastest and is the second array subscript in the expression `X (I,J)`, the array is accessed in row-major order. To make the array accessed in natural column-major order, examine the array algorithm and data being modified. Using arrays `X` and `Y`, the array can be accessed in natural column-major order by changing the nesting order of the `DO` loops so the innermost loop variable corresponds to the leftmost array dimension:

Example

```
INTEGER  X(3,5), Y(3,5), I, J
Y = 0
DO J=1,5                   ! J outer loop varies slowest
  DO I=1,3                 ! I inner loop varies fastest
    X (I,J) = Y(I,J) + 1

  ! Efficient column-major storage order
  END DO                   ! (leftmost subscript varies fastest)
END DO
...
END PROGRAM
```

The Intel Fortran whole array access (`X = Y + 1`) uses efficient column major order. However, if the application requires that `J` vary the fastest or if you cannot modify the loop order without changing the results, consider modifying the application to use a rearranged order of array dimensions. Program modifications include rearranging the order of:

- Dimensions in the declaration of the arrays `X(5,3)` and `Y(5,3)`
- The assignment of `X(J,I)` and `Y(J,I)` within the `DO` loops

- All other references to arrays `X` and `Y`

In this case, the original `DO` loop nesting is used where `J` is the innermost loop:

Example

```
INTEGER  X(5,3), Y(5,3), I, J
Y = 0
DO I=1,3                  ! I outer loop varies slowest
  DO J=1,5                ! J inner loop varies fastest
    X (J,I) = Y(J,I) + 1

 ! Efficient column-major storage order
  END DO                  ! (leftmost subscript varies fastest)
END DO
...
END PROGRAM
```

Code written to access multidimensional arrays in row-major order (like C) or random order can often make inefficient use of the CPU memory cache. For more information on using natural storage order during record, see Improving I/O Performance.

Use available intrinsics

Whenever possible, use Fortran array intrinsic procedures instead of creating your own routines to accomplish the same task. Fortran array intrinsic procedures are designed for efficient use with the various Intel Fortran run-time components.

Using the standard-conforming array intrinsics can also make your program more portable.

Avoid leftmost array dimensions

With multidimensional arrays where access to array elements will be noncontiguous, avoid leftmost array dimensions that are a power of two (such as 256, 512).

Since the cache sizes are a power of 2, array dimensions that are also a power of 2 may make inefficient use of cache when array access is noncontiguous. If the cache size is an exact multiple of the leftmost dimension, your program will probably make use of the cache less efficient. This does not apply to contiguous sequential access or whole array access.

One work-around is to increase the dimension to allow some unused elements, making the leftmost dimension larger than actually needed. For example, increasing the leftmost dimension of A from 512 to 520 would make better use of cache:

Example

```
REAL A (512,100)
DO I = 2,511
  DO J = 2,99
    A(I,J)=(A(I+1,J-1) + A(I-1, J+1)) * 0.5
  END DO
END DO
```

In this code, array A has a leftmost dimension of 512, a power of two. The innermost loop accesses the rightmost dimension (row major), causing inefficient access. Increasing the leftmost dimension of `A to 520 (REAL A (520,100))` allows the loop to provide better performance, but at the expense of some unused elements.

Because loop index variables *I* and *J* are used in the calculation, changing the nesting order of the `DO` loops changes the results.

For more information on arrays and their data declaration statements, see the *Intel® Fortran Language Reference*.

Passing Array Arguments Efficiently

In Fortran, there are two general types of array arguments:

- Explicit-shape arrays (introduced with Fortran 77); for example, `A(3,4)` and `B(0:*)`

These arrays have a fixed rank and extent that is known at compile time. Other dummy argument (receiving) arrays that are not deferred-shape (such as assumed-size arrays) can be grouped with explicit-shape array arguments.

- Deferred-shape arrays (introduced with Fortran 95/90); for example, `C(:,:)`

Types of deferred-shape arrays include array pointers and allocatable arrays. Assumed-shape array arguments generally follow the rules about passing deferred-shape array arguments.

When passing arrays as arguments, either the starting (base) address of the array or the address of an array descriptor is passed:

- When using explicit-shape (or assumed-size) arrays to receive an array, the starting address of the array is passed.
- When using deferred-shape or assumed-shape arrays to receive an array, the address of the array descriptor is passed (the compiler creates the array descriptor).

Passing an assumed-shape array or array pointer to an explicit-shape array can slow run-time performance. This is because the compiler needs to create an array temporary for the entire array. The array temporary is created because the passed array may not be contiguous and the receiving (explicit-shape) array requires a contiguous array. When an array temporary is created, the size of the passed array determines whether the impact on slowing run-time performance is slight or severe.

The following table summarizes what happens with the various combinations of array types. The amount of run-time performance inefficiency depends on the size of the array.

	Dummy Argument Array Types (choose one)	
Actual Argument Array Types (choose one)	Explicit-Shape Arrays	Deferred-Shape and Assumed-Shape Arrays
Explicit-Shape Arrays	Result when using this combination: Very efficient. Does not use an array temporary. Does not pass an array descriptor. Interface block optional.	Result when using this combination: Efficient. Only allowed for assumed-shape arrays (not deferred-shape arrays). Does not use an array temporary. Passes an array descriptor. Requires an interface block.

Deferred-Shape and Assumed-Shape Arrays	Result when using this combination: When passing an allocatable array, very efficient. Does not use an array temporary. Does not pass an array descriptor. Interface block optional. When not passing an allocatable array, not efficient. Instead use allocatable arrays whenever possible. Uses an array temporary. Does not pass an array descriptor. Interface block optional.	Result when using this combination: Efficient. Requires an assumed-shape or array pointer as dummy argument. Does not use an array temporary. Passes an array descriptor. Requires an interface block.

Improving I/O Performance

Improving overall I/O performance can minimize both device I/O and actual CPU time. The techniques listed in this topic can significantly improve performance in many applications.

An I/O flow problems limit the maximum speed of execution by being the slowest process in an executing program. In some programs, I/O is the bottleneck that prevents an improvement in run-time performance. The key to relieving I/O problems is to reduce the actual amount of CPU and I/O device time involved in I/O.

The problems can be caused by one or more of the following:

- A dramatic reduction in CPU time without a corresponding improvement in I/O time.
- Such coding practices as:
- - Unnecessary formatting of data and other CPU-intensive processing
  - Unnecessary transfers of intermediate results
  - Inefficient transfers of small amounts of data
  - Application requirements

Improved coding practices can minimize actual device I/O, as well as the actual CPU time. Intel offers software solutions to system-wide problems like minimizing device I/O delays.

Use Unformatted Files Instead of Formatted Files

Use unformatted files whenever possible. Unformatted I/O of numeric data is more efficient and more precise than formatted I/O. Native unformatted data does not need to be modified when transferred and will take up less space on an external file.

Conversely, when writing data to formatted files, formatted data must be converted to character strings for output, less data can transfer in a single operation, and formatted data may lose precision if read back into binary form.

To write the array `A(25,25)` in the following statements, `S1` is more efficient than `S2`:

Example

```
S1          WRITE (7) A
S2          WRITE (7,100) A
100    FORMAT (25(' ',25F5.21))
```

Although formatted data files are more easily ported to other systems, Intel Fortran can convert unformatted data in several formats; see Little-endian-to-Big-endian Conversion (IA-32 architecture).

Write Whole Arrays or Strings

To eliminate unnecessary overhead, write whole arrays or strings at one time rather than individual elements at multiple times. Each item in an I/O list generates its own calling sequence. This processing overhead becomes most significant in implied-`DO` loops. When accessing whole arrays, use the array name (Fortran array syntax) instead of using implied-`DO` loops.

Write Array Data in the Natural Storage Order

Use the natural ascending storage order whenever possible. This is column-major order, with the leftmost subscript varying fastest and striding by 1. (See Accessing Arrays Efficiently.) If a program must read or write data in any other order, efficient block moves are inhibited.

If the whole array is not being written, natural storage order is the best order possible.

If you must use an unnatural storage order, in certain cases it might be more efficient to transfer the data to memory and reorder the data before performing the I/O operation.

Use Memory for Intermediate Results

Performance can improve by storing intermediate results in memory rather than storing them in a file on a peripheral device. One situation that may not benefit from using intermediate storage is when there is a disproportionately large amount of data in relation to physical memory on your system. Excessive page faults can dramatically impede virtual memory performance.

Linux*: If you are primarily concerned with the CPU performance of the system, consider using a memory file system (mfs) virtual disk to hold any files your code reads or writes.

Enable Implied-DO Loop Collapsing

`DO` loop collapsing reduces a major overhead in I/O processing. Normally, each element in an I/O list generates a separate call to the Intel Fortran run-time library (RTL). The processing overhead of these calls can be most significant in implied-`DO` loops.

Intel Fortran reduces the number of calls in implied-`DO` loops by replacing up to seven nested implied-`DO` loops with a single call to an optimized run-time library I/O routine. The routine can transmit many I/O elements at once.

Loop collapsing can occur in formatted and unformatted I/O, but only if certain conditions are met:

- The control variable must be an integer. The control variable cannot be a dummy argument or contained in an `EQUIVALENCE` or `VOLATILE` statement. Intel Fortran must be able to determine that the control variable does not change unexpectedly at run time.
- The format must not contain a variable format expression.

For information on the `VOLATILE` attribute and statement, see the *Intel© Fortran Language Reference*.

Use of Variable Format Expressions

Variable format expressions (an Intel Fortran extension) are almost as flexible as run-time formatting, but they are more efficient because the compiler can eliminate run-time parsing of the I/O format. Only a small amount of processing and the actual data transfer are required during run time.

On the other hand, run-time formatting can impair performance significantly. For example, in the following statements, `S1` is more efficient than `S2` because the formatting is done once at compile time, not at run time:

Example

```
S1        WRITE (6,400) (A(I), I=1,N)
400

 FORMAT (1X, <N> F5.2)
...
S2        WRITE (CHFMT,500) '(1X,',N,'F5.2)'
500

 FORMAT (A,I3,A)
WRITE (6,FMT=CHFMT) (A(I), I=1,N)
```

Efficient Use of Record Buffers and Disk I/O

Records being read or written are transferred between the user's program buffers and one or more disk block I/O buffers, which are established when the file is opened by the Intel Fortran RTL. Unless very large records are being read or written, multiple logical records can reside in the disk block I/O buffer when it is written to disk or read from disk, minimizing physical disk I/O.

You can specify the size of the disk block physical I/O buffer by using the `OPEN` statement `BLOCKSIZE` specifier; the default size can be obtained from `fstat(2)`. If you omit the `BLOCKSIZE` specifier in the `OPEN` statement, it is set for optimal I/O use with the type of device the file resides on (with the exception of network access).

The `OPEN` statement `BUFFERCOUNT` specifier specifies the number of I/O buffers. The default for `BUFFERCOUNT` is 1. Any experiments to improve I/O performance should increase the `BUFFERCOUNT` value and not the `BLOCKSIZE` value, to increase the amount of data read by each disk I/O.

If the `OPEN` statement has `BLOCKSIZE` and `BUFFERCOUNT` specifiers, then the internal buffer size in bytes is the product of these specifiers. If the `open` statement does not have these specifiers, then the default internal buffer size is 8192 bytes. This internal buffer will grow to hold the largest single record, but will never shrink.

The default for the Fortran run-time system is to use unbuffered disk writes. That is, by default, records are written to disk immediately as each record is written instead of accumulating in the buffer to be written to disk later.

To enable buffered writes (that is, to allow the disk device to fill the internal buffer before the buffer is written to disk), use one of the following:

- The `OPEN` statement `BUFFERED` specifier
- The `-assume buffered_io` (Linux*) or `/assume:buffered_io` (Windows*) option of the `ASSUME` command
- The `FORT_BUFFERED` run-time environment variable

The `OPEN` statement `BUFFERED` specifier takes precedence over the `-assume buffered_io` (Linux) or `/assume:buffered_io` (Windows) option. If neither one is set (which is the default), the `FORT_BUFFERED` environment variable is tested at run time.

The `OPEN` statement `BUFFERED` specifier applies to a specific logical unit. In contrast, the `-assume nobuffered_io` (Linux) or `/assume:nobuffered_io` (Windows) option and the `FORT_BUFFERED` environment variable apply to all Fortran units.

Using buffered writes usually makes disk I/O more efficient by writing larger blocks of data to the disk less often. However, a system failure when using buffered writes can cause records to be lost, since they might not yet have been written to disk. (Such records would have been written to disk with the default unbuffered writes.)

When performing I/O across a network, be aware that the size of the block of network data sent across the network can impact application efficiency. When reading network data, follow the same advice for efficient disk reads, by increasing the `BUFFERCOUNT`. When writing data through the network, several items should be considered:

- Unless the application requires that records be written using unbuffered writes, enable buffered writes by a method described above.
- Especially with large files, increasing the `BLOCKSIZE` value increases the size of the block sent on the network and how often network data blocks get sent.
- Time the application when using different `BLOCKSIZE` values under similar conditions to find the optimal network block size.

Completion of a `WRITE` statement, even when not buffered, does not guarantee that the data has been written to disk; the operating system may delay the actual disk write. To ensure that the data has been written to disk, you can call the `FLUSH` routine. Because this can cause a significant slowdown of the application, `FLUSH` should be used only when absolutely needed.

Linux* Only: When writing records, be aware that I/O records are written to unified buffer cache (UBC) system buffers. To request that I/O records be written from program buffers to the UBC system buffers, use the FLUSH library routine. Be aware that calling FLUSH also discards read-ahead data in user buffer. For more information, see `FLUSH` in the *Intel® Fortran Libraries Reference.*

Specify RECL

The sum of the record length (`RECL` specifier in an `OPEN` statement) and its overhead is a multiple or divisor of the blocksize, which is device-specific. For example, if the `BLOCKSIZE` is 8192 then `RECL` might be 24576 (a multiple of 3) or 1024 (a divisor of 8).

The `RECL` value should fill blocks as close to capacity as possible (but not over capacity). Such values allow efficient moves, with each operation moving as much data as possible; the least amount of space in the block is wasted. Avoid using values larger than the block capacity, because they create very inefficient moves for the excess data only slightly filling a block (allocating extra memory for the buffer and writing partial blocks are inefficient).

The `RECL` value unit for formatted files is always 1-byte units. For unformatted files, the `RECL` unit is 4-byte units, unless you specify the `-assume byterecl` (Linux) or `/assume:byterecl` (Windows) option for the `ASSUME` specifier to request 1-byte units.

Use the Optimal Record Type

Unless a certain record type is needed for portability reasons, choose the most efficient type, as follows:

- For sequential files of a consistent record size, the fixed-length record type gives the best performance.
- For sequential unformatted files when records are not fixed in size, the variable-length record type gives the best performance, particularly for `BACKSPACE` operations.
- For sequential formatted files when records are not fixed in size, the `Stream_LF` record type gives the best performance.

Reading from a Redirected Standard Input File

Due to certain precautions that the Fortran run-time system takes to ensure the integrity of standard input, reads can be very slow when standard input is redirected from a file. For example, when you use a command such as `myprogram.exe < myinput.data>` , the data is read using the `READ(*)` or `READ(5)` statement, and performance is degraded. To avoid this problem, do one of the following:

- Explicitly open the file using the `OPEN` statement. For example: `OPEN(5, STATUS='OLD', FILE='myinput.dat')`
- Use an environment variable to specify the input file.

To take advantage of these methods, be sure your program does not rely on sharing the standard input file.

For more information on Intel Fortran data files and I/O, see Files, Devices, and I/O in the Building Applications; on `OPEN` statement specifiers and defaults, see Open Statement in the *Intel® Fortran Language Reference*.

Improving Run-time Efficiency

Use these source-coding guidelines to improve run-time performance. The amount of improvement in run-time performance is related to the number of times a statement is executed. For example, improving an arithmetic expression executed within a loop many times has the potential to improve performance, more than improving a similar expression executed once outside a loop.

Avoid Small Integer and Small Logical Data Items

Avoid using integer or logical data less than 32 bits. Accessing a 16-bit (or 8-bit) data type can make data access less efficient, especially on IA-64 architecture based systems.

To minimize data storage and memory cache misses with arrays, use 32-bit data rather than 64-bit data, unless you require the greater numeric range of 8-byte integers or the greater range and precision of double precision floating-point numbers.

Avoid Using Slow Arithmetic Operators

Before you modify source code to avoid slow arithmetic operators, be aware that optimizations convert many slow arithmetic operators to faster arithmetic operators. For example, the compiler optimizes the expression `H=J**2` to be `H=J*J`.

Consider also whether replacing a slow arithmetic operator with a faster arithmetic operator will change the accuracy of the results or impact the maintainability (readability) of the source code.

Replacing slow arithmetic operators with faster ones should be reserved for critical code areas. The following list shows the Intel Fortran arithmetic operators, from fastest to slowest:

1. Addition (+), Subtraction (-), and Floating-point multiplication (*)
2. Integer multiplication (*)
3. Division (/)
4. Exponentiation (**)

Avoid Using EQUIVALENCE Statements

Avoid using `EQUIVALENCE` statements. `EQUIVALENCE` statements can:

- Force unaligned data or cause data to span natural boundaries.
- Prevent certain optimizations, including:
  - Global data analysis under certain conditions; see the `-O2` (Linux*) or `/O2` (Windows*) option description for more information.
  - Implied-`DO` loop collapsing when the control variable is contained in an `EQUIVALENCE` statement

Use Statement Functions and Internal Subprograms

Whenever the Intel compiler has access to the use and definition of a subprogram during compilation, it may choose to inline the subprogram. Using statement functions and internal subprograms maximizes the number of subprogram references that will be inlined, especially when multiple source files are compiled together at optimization level `-O3` (Linux) or `/O3` (Windows).

For more information, see Efficient Compilation.

Code DO Loops for Efficiency

Minimize the arithmetic operations and other operations in a `DO` loop whenever possible. Moving unnecessary operations outside the loop will improve performance (for example, when the intermediate nonvarying values within the loop are not needed).

Using Fortran Intrinsics

Intel® Fortran supports all standard Fortran intrinsic procedures and provides Intel-specific intrinsic procedures to extend the language functionality. The Intel-specific intrinsic procedures are provided in `libifcore.lib`. For more details on these intrinsic procedures, see the *Intel® Fortran Language Reference*.

This topic provides an example of an Intel-extended intrinsic that is helpful in developing efficient applications on IA-32, Intel® 64, and IA-64 architectures.

CACHESIZE Intrinsic

The intrinsic `CACHESIZE(n)` returns the size in kilobytes of the cache at level `n`; one (1) represents the first level cache. Zero (0) is returned for a nonexistent cache level.

Use this intrinsic in any situation you would like to tailor algorithms for the cache hierarchy on the target processor. For example, an application may query the cache size and use the result to select block sizes in algorithms that operate on matrices.

Example

```
subroutine foo (level)
integer level
if (cachesize(level) > threshold) then
   call big_bar()
else
   call small_bar()
end if
end subroutine
```

Understanding Run-time Performance

The information in this topic assumes that you are using a performance optimization methodology and have analyzed the application type you are optimizing.

After profiling your application to determine where best to spend your time, attempt to discover what optimizations and what limitations have been imposed by the compiler. Use the compiler reports to determine what to try next.

Depending on what you discover from the reports you may be able to help the compiler through options, directives, and slight code modifications to take advantage of key architectural features to achieve the best performance.

The compiler reports can describe what actions have been taken and what actions cannot be taken based on the assumptions made by the compiler. Experimenting with options and directives allows you to use an understanding of the assumptions and suggest a new optimization strategy or technique.

Helping the Compiler

You can help the compiler in some important ways:

- Read the appropriate reports to gain an understanding of what the compiler is doing for you and the assumptions the compiler has made with respect to your code.
- Use specific options, intrinsics, libraries, and directives to get the best performance from your application.

Use the Math Kernel Library (MKL) instead of user code, or calling F90 intrinsics instead of user code.

See Applying Optimization Strategies for other suggestions.

Memory Aliasing For IA-64 Architectures

Memory aliasing is the single largest issue affecting the optimizations in the Intel® compiler for IA-64 architecture based systems. Memory aliasing is writing to a given memory location with more than one pointer. The compiler is cautious to not optimize too aggressively in these cases; if the compiler optimizes too aggressively, unpredictable behavior can result (for example, incorrect results, abnormal termination, etc.).

Since the compiler usually optimizes on a module-by-module, function-by-function basis, the compiler does not have an overall perspective with respect to variable use for global variables or variables that are passed into a function; therefore, the compiler usually assumes that any pointers passed into a function are likely to be aliased. The compiler makes this assumption even for pointers you know are not aliased. This behavior means that perfectly safe loops do not get pipelined or vectorized, and performance suffers.

There are several ways to instruct the compiler that pointers are not aliased:

- Use a comprehensive compiler option, such as `-fno-alias` (Linux*) or `/Oa` (Windows*). These options instruct the compiler that no pointers in any module are aliased, placing the responsibility of program correctness directly with the developer.

- Use a less comprehensive option, like `-fno-fnalias` (Linux) or `/Ow` (Windows). These options instruct the compiler that no pointers passed through function arguments are aliased.

  Function arguments are a common example of potential aliasing that you can clarify for the compiler. You may know that the arguments passed to a function do not alias, but the compiler is forced to assume so. Using these options tells the compiler it is now safe to assume that these function arguments are not aliased. This option is still a somewhat bold statement to make, as it affects all functions in the module(s) compiled with the `-fno-nalias` (Linux) or `/Ow` (Windows) option.
- Use the `IDVEP` directive. Alternatively, you might use a directive that applies to a specified loop in a function. This is more precise than specifying an entire function. The directive asserts that, for a given loop, there are no vector dependencies. Essentially, this is the same as saying that no pointers are aliasing in a given loop.

Non-Unit Stride Memory Access

Another issue that can have considerable impact on performance is accessing memory in a non-Unit Stride fashion. This means that as your inner loop increments consecutively, you access memory from non adjacent locations. For example, consider the following matrix multiplication code:

Example

```
!Non-Unit Stride Memory Access
subroutine non_unit_stride_memory_access(a,b,c, NUM)
  implicit none
  integer :: i,j,k,NUM
  real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
! loop before loop interchange
  do i=1,NUM
    do j=1,NUM
      do k=1,NUM
        c(j,i) = c(j,i) + a(j,k) * b(k,i)
      end do
    end do
  end do
end subroutine non_unit_stride_memory_access
```

Notice that `c[i][j]`, and `a[i][k]` both access consecutive memory locations when the inner-most loops associated with the array are incremented. The *b* array however, with its loops with indexes k and j, does not access Memory Unit Stride. When the loop reads `b[k=0][j=0]` and then the k loop increments by one to `b[k=1][j=0]`, the loop has skipped over NUM memory locations having skipped `b[k][1], b[k][2] .. b[k][NUM].`

Loop transformation (sometimes called loop interchange) helps to address this problem. While the compiler is capable of doing loop interchange automatically, it does not always recognize the opportunity.

The memory access pattern for the example code listed above is illustrated in the following figure:

Assume you modify the example code listed above by making the following changes to introduce loop interchange:

Example

```
subroutine unit_stride_memory_access(a,b,c, NUM)
  implicit none
  integer :: i,j,k,NUM
  real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
! loop after interchange
  do i=1,NUM
    do k=1,NUM
      do j=1,NUM
        c(j,i) = c(j,i) + a(j,k) * b(k,i)
      end do
    end do
  end do
end subroutine unit_stride_memory_access
```

After the loop interchange the memory access pattern might look the following figure:

Understanding Data Alignment

Aligning data on boundaries can help performance. The Intel® compiler attempts to align data on boundaries for you. However, as in all areas of optimization, coding practices can either help or hinder the compiler and can lead to performance problems.

Always attempt to optimize using compiler options first.

To avoid performance problems you should keep the following guidelines in mind, which are separated by architecture:

IA-32, Intel® 64, and IA-64 architectures:

- Do not access or create data at large intervals that are separated by exactly 2^n (for example, 1 KB, 2 KB, 4 KB, 16 KB, 32 KB, 64 KB, 128 KB, 512 KB, 1 MB, 2 MB, 4 MB, 8 MB, etc.).
- Align data so that memory accesses does not cross cache lines (for example, 32 bytes, 64 bytes, 128 bytes).
- Use Application Binary Interface (ABI) for the Itanium® compiler to insure that ITP pointers are 16-byte aligned.

IA-32 and Intel® 64 architectures:

- Align data to correspond to the SIMD or Streaming SIMD Extension registers sizes.

IA-64 architecture:

- Avoid using packed structures.
- Avoid casting pointers of small data elements to pointers of large data elements.
- Do computations on unpacked data, then repack data if necessary, to correctly output the data.

In general, keeping data in cache has a better performance impact than keeping the data aligned. Try to use techniques that conform to the rules listed above.

See Setting Data Type and Alignment for more detailed information on aligning data.

Timing Your Application

You can start collecting information about your application performance by timing your application. More sophisticated and helpful data can be collected by using performance analysis tools.

Considerations on Timing Your Application

One of the performance indicators is your application timing. The following considerations apply to timing your application:

- Run program timings when other users are not active. Your timing results can be affected by one or more CPU-intensive processes also running while doing your timings.
- Try to run the program under the same conditions each time to provide the most accurate results, especially when comparing execution times of a previous version of the same program. Use the same system (processor model, amount of memory, version of the operating system, and so on) if possible.

- If you do need to change systems, you should measure the time using the same version of the program on both systems, so you know each system's effect on your timings.
- For programs that run for less than a few seconds, run several timings to ensure that the results are not misleading. Certain overhead functions like loading libraries might influence short timings considerably.
- If your program displays a lot of text, consider redirecting the output from the program. Redirecting output from the program will change the times reported because of reduced screen I/O.

  Timings that show a large amount of system time may indicate a lot of time spent doing I/O, which might be worth investigating.
- For programs that run for less than a few seconds, run several timings to ensure that the results are not misleading. Overhead functions like loading shared libraries might influence short timings considerably.

  Use the `time` command and specify the name of the executable program to provide the following:

  - The elapsed, real, or "wall clock" time, which will be greater than the total charged actual CPU time.
  - Charged actual CPU time, shown for both system and user execution. The total actual CPU time is the sum of the actual user CPU time and actual system CPU time.

Methods of Timing Your Application

To perform application timings, use a version of the `TIME` command in a `.BAT` file (or the function timing profiling option). You might consider modifying the program to call routines within the program to measure execution time (possibly using conditionally compiled lines).

For example:

- Intel Fortran intrinsic procedures, such as `SECNDS`, `CPU_TIME`, `SYSTEM_CLOCK`, `TIME`, and `DATE_AND_TIME`.
- Portability library routines, such as `DCLOCK`, `ETIME`, `SECNDS`, or `TIME`.

Whenever possible, perform detailed performance analysis on a system that closely resembles the system(s) that will be used for actual application use.

Sample Timing

The following program template could be run by a `.BAT` file that executes the `TIME` command both before and after execution, to provide an approximate wall-clock time for the execution of the entire program. The Fortran intrinsic `CPU_TIME` can be used at selected points in the program to collect the CPU time between the start and end of the task to be timed.

Example

```
REAL time_begin, time_end
  ...
  CALL CPU_TIME ( time_begin )
  !
  !task to be timed
  !
  CALL CPU_TIME ( time_end )
  PRINT *, 'Time of operation was ', &
time_end - time_begin, ' seconds'
```

Considerations for Linux*

In the following example timings, the sample program being timed displays the following line:

Bourne* shell example

```
Average of all the numbers is:    4368488960.000000
```

Using the Bourne* shell, the following program timing reports that the program uses 1.19 seconds of total actual CPU time (0.61 seconds in actual CPU time for user program use and 0.58 seconds of actual CPU time for system use) and 2.46 seconds of elapsed time:

Bourne* shell example

```
$ time a.out
Average of all the numbers is:
4368488960.000000
real    0m2.46s
user    0m0.61s
sys     0m0.58s
```

Using the C shell, the following program timing reports 1.19 seconds of total actual CPU time (0.61 seconds in actual CPU time for user program use and 0.58 seconds of actual CPU time for system use), about 4 seconds (0:04) of elapsed time, the use of 28% of available CPU time, and other information:

C shell l example

```
% time a.out
Average of all the numbers is:   4368488960.000000
0.61u 0.58s 0:04 28% 78+424k 9+5io 0pf+0w
```

Using the bash shell, the following program timing reports that the program uses 1.19 seconds of total actual CPU time (0.61 seconds in actual CPU time for user program use and 0.58 seconds of actual CPU time for system use) and 2.46 seconds of elapsed time:

bash shell l example

```
[user@system user]$ time ./a.out
Average of all the numbers is:   4368488960.000000
elapsed  0m2.46s
user     0m0.61s
sys      0m0.58s
```

Timings that indicate a large amount of system time is being used may suggest excessive I/O, a condition worth investigating.

If your program displays a lot of text, you can redirect the output from the program on the time command line. Redirecting output from the program will change the times reported because of reduced screen I/O.

For more information, see `time(1)`.

In addition to the `time` command, you might consider modifying the program to call routines within the program to measure execution time. For example, use the Intel intrinsic procedures, such as `SECNDS`, `DCLOCK`, `CPU_TIME`, `SYSTEM_CLOCK`, `TIME`, and `DATE_AND_TIME`.

Applying Optimization Strategies

The compiler may or may not apply the following optimizations to your loop: Interchange, Unrolling, Cache Blocking, and LoadPair. These transformations are discussed in the following sections, including how to transform loops manually and how to control them with directives or internal options.

Loop Interchange

Loop Interchange is a nested loop transformation applied by High-level Optimization (HLO) that swaps the order of execution of two nested loops. Typically, the transformation is performed to provide sequential Unit Stride access to array elements used inside the loop to improve cache locality. The compiler `-O3` (Linux* and Mac OS* X) or `/O3` (Windows*) optimization looks for opportunities to apply loop interchange for you.

The following is an example of a loop interchange

Example

```
subroutine loop_interchange(a,b,c, NUM)
implicit none
integer :: i,j,k,NUM
real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
! loop before loop interchange
do i=1,NUM
  do j=1,NUM
    do k=1,NUM
        c(j,i) = c(j,i) + a(j,k) * b(k,i)
    end do
  end do
end do
! loop after interchange
do i=1,NUM
  do k=1,NUM
    do j=1,NUM
        c(j,i) = c(j,i) + a(j,k) * b(k,i)
    end do
  end do
end do
end subroutine loop_interchange
```

Unrolling

Loop unrolling is a loop transformation generally used by HLO that can take better advantage of Instruction-Level Parallelism (ILP), keeping as many functional units busy doing useful work as possible during single loop iteration. In loop unrolling, you add more work to the inside of the loop while doing fewer loop iterations in exchange.

Example

```
subroutine loop_unroll_before(a,b,c,N,M)
implicit none
integer :: i,j,N,M
real :: a(N,M), b(N,M), c(N,M)
N=1025
M=5
do i=1,N
  do j=1,M
    a(j,i) = b(j,i) + c(j,i)
  end do
end do
end subroutine loop_unroll_before
```

Example

```
subroutine loop_unroll_after(a,b,c,N,M)
implicit none
integer :: i,j,K,N,M
real :: a(N,M), b(N,M), c(N,M)
N=1025
M=5
K=MOD(N,4)  !K= N MOD 4
! main part of loop
```

Example

```
do i=1,N-K,4
  do j=1,M
    a(j,i) = b(j,i) + c(j,i)
    a(j,i+1) = b(j,i+1) + c(j,i+1)
    a(j,i+2) = b(j,i+2) + c(j,i+2)
    a(j,i+3) = b(j,i+3) + c(j,i+3)
  end do
end do
! post conditioning part of loop
do i= N-K+2, N, 4
  do j=1,M
    a(j,i) = b(j,i) + c(j,i)
  end do
end do
end subroutine loop_unroll_after
```

Post conditioning is preferred over pre-conditioning because post conditioning will preserve the data alignment and avoid the cost of memory alignment access penalties.

Cache Blocking

Cache blocking involves structuring data blocks so that they conveniently fit into a portion of the L1 or L2 cache. By controlling data cache locality, an application can minimize performance delays due to memory bus access. The application controls the behavior by dividing a large array into smaller blocks of memory so a thread can make repeated accesses to the data while the data is still in cache.

For example, image processing and video applications are well suited to cache blocking techniques because an image can be processed on smaller portions of the total image or video frame. Compilers often use the same technique, by grouping related blocks of instructions close together so they execute from the L2 cache.

The effectiveness of the cache blocking technique depends on data block size, processor cache size, and the number of times the data is reused. Cache sizes vary based on processor. An application can detect the data cache size using the `CPUID` instruction and dynamically adjust cache blocking tile sizes to maximize performance. As a general rule, cache block sizes should target approximately one-half to three-quarters the size of the physical cache. For systems that are Hyper-Threading Technology (HT Technology) enabled target one-quarter to one-half the physical cache size. Designing for Hyper-Threading Technology

Cache blocking is applied in HLO and is used on large arrays where the arrays cannot all fit into cache simultaneously. This method is one way of pulling a subset of data into cache (in a small region), and using this cached data as effectively as possible before the data is replaced by new data from memory.

Example

```
subroutine cache_blocking_before(a,b,N)
  implicit none
  integer :: i,j,k,N
  real :: a(N,N,N), b(N,N,N), c(N,N,N)
  N=1000
  do i = 1, N
    do j = 1, N
      do k = 1, N
        a(i,j,k) = a(i,j,k)  + b(i,j,k)
      end do
    end do
  end do
end subroutine cache_blocking_before
subroutine cache_blocking_after(a,b,N)
  implicit none
  integer :: i,j,k,u,v,N
  real :: a(N,N,N), b(N,N,N), c(N,N,N)
  N=1000
  do v = 1, N, 20
    do u = 1, N, 20
      do k = v, v+19
        do j = u, u+19
          do i = 1, N
            a(i,j,k) = a(i,j,k)  + b(i,j,k)
```

Example

```
          end do
        end do
      end do
    end do
  end do
end subroutine cache_blocking_after
```

The cache block size is set to 20. The goal is to read in a block of cache, do every bit of computing we can with the data in this cache, then load a new block of data into cache. There are 20 elements of `A` and 20 elements of `B` in cache at the same time and you should do as much work with this data as you can before you increment to the next cache block.

Blocking factors will be different for different architectures. Determine the blocking factors experimentally. For example, different blocking factors would be required for single precision versus double precision. Typically, the overall impact to performance can be significant.

Loop Distribution

Loop distribution is a high-level loop transformation that splits a large loop into two smaller loops. It can be useful in cases where optimizations like software-pipelining (SWP) or vectorization cannot take place due to excessive register usage. By splitting a loop into smaller segments, it may be possible to get each smaller loop or at least one of the smaller loops to SWP or vectorize. An example is as follows:

Example

```
subroutine loop_distribution_before(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
  do i = 1, N
    a(i) = a(i)  + i
    b(i) = b(i)  + i
    c(i) = c(i)  + i
    x(i) = x(i)  + i
    y(i) = y(i)  + i
    z(i) = z(i)  + i
  end do
end subroutine loop_distribution_before
subroutine loop_distribution_after(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
  do i = 1, N
    a(i) = a(i)  + i
    b(i) = b(i)  + i
```

Example

```
    c(i) = c(i)  + i
  end do
  do i = 1, N
    x(i) = x(i)  + i
    y(i) = y(i)  + i
    z(i) = z(i)  + i
  end do
end subroutine loop_distribution_after
```

There are directives to suggest distributing loops to the compiler as follows:

Example

```
!DEC$ distribute point
```

Placed outside a loop, the compiler will attempt to distribute the loop based on an internal heuristic. The following is an example of using the pragma outside the loop:

Example

```
subroutine loop_distribution_pragma1(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
!DEC$ distribute point
  do i = 1, N
    a(i) = a(i)  + i
    b(i) = b(i)  + i
    c(i) = c(i)  + i
    x(i) = x(i)  + i
    y(i) = y(i)  + i
    z(i) = z(i)  + i
  end do
end subroutine loop_distribution_pragma1
```

Placed within a loop, the compiler will attempt to distribute the loop at that point. All loop-carried dependencies will be ignored. The following example uses the directive within a loop to precisely indicate where the split should take place:

Example

```
subroutine loop_distribution_pragma2(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
  do i = 1, N
    a(i) = a(i)  + i
    b(i) = b(i)  + i
    c(i) = c(i)  + i
!DEC$  distribute point
    x(i) = x(i)  + i
    y(i) = y(i)  + i
    z(i) = z(i)  + i
  end do
end subroutine loop_distribution_pragma2
```

Load Pair (Itanium® Compiler)

Load pairs (ldfp) are instructions that load two contiguous single or double precision values from memory in one move. Load pairs can significantly improve performance.

Manual Loop Transformations

There might be cases where these manual transformations are called acceptable or even preferred. As a general rule, you should let the compiler transform loops for you. Manually transform loops as a last resort; use this strategy only in cases where you are attempting to gain performance increases.

Manual loop transformations have many disadvantages, which include the following:

- Application code becomes harder to maintain over time.
- New compiler features can cause you to lose any optimization you gain by manually transforming the loop.
- Architectural requirements might restrict your code to a specific architecture unintentionally.

The `HLO` report can give you an idea of what loop transformations have been applied by the compiler.

Experimentation is a critical component in manually transforming loops. You might try to apply a loop transformation that the compiler ignored. Sometimes, it is beneficial to apply a manual loop transformation that the compiler has already applied with `-O3` (Linux) or `/O3` (Windows).

Optimizing the Compilation Process

Optimizing the Compilation Process Overview

This section describes the Intel® compiler options that can optimize the compilation process. By default, the compiler converts source code directly to an executable file. Appropriate options enable you not only to control the process and obtain desired output file produced by the compiler, but also make the compilation itself more efficient.

A group of options monitors the outcome of Intel compiler-generated code without interfering with the way your program runs. These options control some computation aspects, such as allocating the stack memory, setting or modifying variable settings, and defining the use of some registers.

The options in this section provide you with the following capabilities of efficient compilation:

- Compiling efficiently
- Using default compiler optimizations
- Automatic allocation of variables and stacks
- Converting little-endian to big-endian
- Symbol visibility attribute options

Efficient Compilation

Efficient compilation contributes to performance improvement. Before you analyze your program for performance improvement, and improve program performance, you should think of efficient compilation itself.

Based on the analysis of your application, you can decide which compiler optimizations and command-line options can improve the run-time performance of your application.

Efficient Compilation Techniques

The efficient compilation techniques can be used during the earlier stages and later stages of program development. During the earlier stages of program development, you can use incremental compilation without optimization. For example:

Linux* and Mac OS* X

Example

`ifort -c -g -O0 sub2.f90`
`ifort -c -g -O0 sub3.f90`
`ifort -o main -g -O0 main.f90 sub2.o sub3.o`

The above commands turn off all compiler default optimizations, for example, `-O2` (Linux* and Mac OS* X) or `/O2` (Windows*), with `-O0` (Linux and Mac OS X) or `/Od` (Windows). You can use the `-g` (Linux) or `/Zi` or `/debug:full` (Windows) option to generate symbolic debugging information and line numbers in the object code for all routines in the program for use by a source-level debugger. The `main` file created in the third command above contains symbolic debugging information as well.

During the later stages of program development, you should specify multiple source files together and use an optimization level of at least `-O2` (Linux and Mac OS X) or `/O2` (Windows) to allow more optimizations to occur. For instance, the following command compiles all three source files together using the default level of optimization:

Linux and Mac OS X

Example
`ifort -o main main.f90 sub2.f90 sub3.f90`

Compiling multiple source files lets the compiler examine more code for possible optimizations, which results in:

- Inlining more procedures
- More complete data flow analysis
- Reducing the number of external references to be resolved during linking

For very large programs, compiling all source files together may not be practical. In such instances, consider compiling source files containing related routines together using multiple `ifort` commands, rather than compiling source files individually.

Stacks: Automatic Allocation and Checking

The options in this group enable you to control the computation of stacks and variables in the compiler generated code.

Automatic Allocation of Variables

`-automatic` (Linux*and Mac OS* X) and `/automatic` (Windows*)

These options specify that locally declared variables are allocated to the run-time stack rather than static storage. If variables defined in a procedure do not have the `SAVE` or `ALLOCATABLE` attribute, they are allocated to the stack. It does not affect variables that appear in an `EQUIVALENCE` or `SAVE` statement, or those that are in `COMMON`.

`-automatic` (Linux and Mac OS X) or `/automatic` (Windows) may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across routine calls should appear in a `SAVE` statement.

NOTE. Linux: If you specify `-recursive` or `-openmp`, the default is `-auto`.

Windows: The Windows NT* system imposes a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `/Qauto` because arrays are allocated on the stack along with scalars.

`-auto-scalar` (Linux and Mac OS X) or `/Qauto-scalar` (Windows)

These options cause allocation of local scalar variables of intrinsic type `INTEGER`, `REAL`, `COMPLEX`, or `LOGICAL` to the stack. This option does not affect variables that appear in an `EQUIVALENCE` or `SAVE` statement, or those that are in `COMMON`.

The `-auto-scalar` (Linux and Mac OS X) or `/Qauto-scalar` (Windows) option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across subroutine calls should appear in a `SAVE` statement. This option is similar to `-auto` (Linux and Mac OS X) and `/Qauto` (Windows) which

causes all local variables to be allocated on the stack. The difference is that `-auto-scalar` (Linux and Mac OS X) or `/Qauto-scalar` (Windows) allocates only scalar variables of the stated above intrinsic types to the stack.

NOTE. Windows: Windows NT* imposes a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `/Qauto` because arrays are allocated on the stack along with scalars. However, with `/Qauto-scalar`, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty.

`-auto-scalar` (Linux and Mac OS X) or `/Qauto-scalar` (Windows) enables the compiler to make better choices about which variables should be kept in registers during program execution.

`-save`, `-zero[-]` (Linux and Mac OS X) or `/Qsave`, `/Qzero[-]` (Windows)

The `-save` (Linux and Mac OS X) or `/Qsave` (Windows) option is opposite of `-auto` (Linux) or `/Qauto` (Windows). The `-save` (Linux and Mac OS X) or `/Qsave` (Windows) option saves all variables in static allocation except local variables within a recursive routine.

If a routine is invoked more than once, this option forces the local variables to retain their values from the last invocation. The `save` option ensures that the final results on the exit of the routine is saved on memory and can be reused at the next occurrence of that routine. This may cause some performance degradation as it causes more frequent rounding of the results.

NOTE. Linux and Mac OS X: `-save` is the same as `-noauto`.

Windows: `/Qsave` is the same as `/save`, and `/noautomatic`.

When the compiler optimizes the code, the results are stored in registers.

The `-zero[-]` (Linux and Mac OS X) or `/Qzero[-]` (Windows) option initializes to zero all local scalar variables of intrinsic type `INTEGER`, `REAL`, `COMPLEX`, or `LOGICAL`, which are saved and not initialized yet. Used in conjunction with `SAVE`.

Summary

There are three options for allocating variables: `-save` (Linux and Mac OS X) or `/Qsave` (Windows), `-auto` (Linux) or `/Qauto` (Windows) and `-auto-scalar` (Linux) or `/Qauto-scalar` (Windows). Only one of these three can be specified.

The correlation among them is as follows:

- -save (Linux and Mac OS X) or /Qsave (Windows) disables -auto (Linux and Mac OS X) or /Qauto (Windows), sets -noauto (Linux and Mac OS X) or /noautomatic (Windows), and allocates all variables not marked AUTOMATIC to static memory.
- -auto (Linux and Mac OS X) or /Qauto (Windows) disables -save (Linux and Mac OS X) or /Qsave (Windows), sets -nosave (Linux and Mac OS X) or /automatic (Windows) and allocates all variables, scalars and arrays of all types, not marked SAVE to the stack.
